Keywords: Speech Coding Algorithm; Embedded Structure; Ultra-low-bit-rate; Enhanced Mixed Excitation Linear Prediction

Abstract. Ultra-low-bit-rate speech coding algorithm was in great demand for many fields such as underwater speech communications. Underwater speech communication for middle-long distance has the characteristics of narrow bandwidth as well as low transmission rate, which makes the underwater speech communication much difficult. Ultra-low-bit-rate speech coding algorithm plays an important role on this occasion. More over, it will be more flexible for the underwater speech communication system if the speech coding algorithm has an embedded structure. The paper introduced the principle of an embedded speech coding algorithm with dual rates at both 300bps and 400bps based on the enhanced mixed excitation linear prediction model. The results show that this embedded ultra-low-bit-rate speech coding algorithm has satisfactory quality under both DRT and MOS test.

Introduction

Underwater speech communication was in great demand in many fields such as frogman work. The quality of analogue speech communication device wasn't satisfying when used in underwater communication. With the development of modern military as well as the improvement of utilizing the resource of the sea, the research on digital speech communication was getting more and more important and had been extensively studied in recent years [1-4], in which speech coding algorithms played an important role. The enhanced mixed excitation linear prediction (MELPE) model show great advantage in ultra-low-bit-rate speech coding algorithms [5-8], based on which the paper proposed an embedded speech coding algorithm with dual rates at both 300bps and 400bps.

Principle of the Encoder

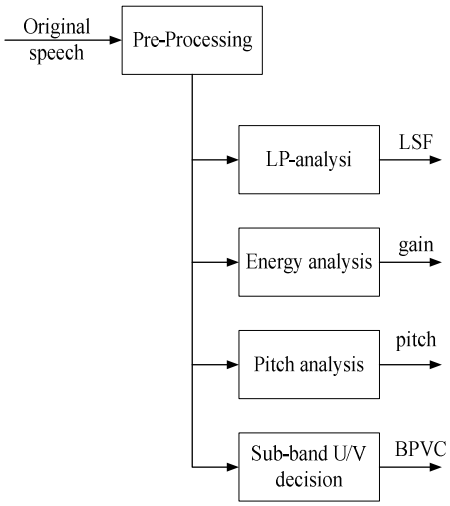

Fig.1. Encoder structure based on MELPE

Four parameters should be extracted for the ultra-low-bit-rate speech coder based on MELPE, which contains linear spectral frequency parameters (LSF), band pass voicing coefficients (BPVC) and pith parameter and gain parameter as shown in Fig.1.

The frame size of the coder introduced is 22.5 ms, the same as for the original MELPE coder. Parameters above are extracted once each frame, but they are usually vector quantized once each super frame combined by several frames because of the fewer bits afforded by the ultra-low-bit-rate speech coder. Each super frame consists of 8 frames, for which the parameters were vector quantized. The super frame is 180ms, and total 54 bits and 72bits could be used for the 300bps and 400bps coder respectively. The bit allocation scheme for this embedded speech coding algorithm is shown as Table 1.

Table 1. Bit allocation scheme for the coder

Parameter	Bit Number	
	300 bps	400bps
BPVC	5	5
Pitch	10	16
Gain	8	11
LSF	31	40
Total	54	72

The BPVC parameter was vector quantized using 5 bits. The corresponding voicing pattern is used to determine the encoding/decoding mode which would be used in the quantization of the other parameters. A weighted Euclidean distance is used to find the optimal voicing pattern, and the corresponding weight vector is applied to the sub-band voicing information {16, 8, 4, 2, 1}.

The LSF parameter took an important role in the synthetic speech quality, so more than half of the bits would be used in the LSF quantization. Suppose the LSF vector of the current super frame was $l_n=\{l_{n,1},l_{n,2},...,l_{n,8}\}$, the quantized LSF vector of the final frame in the last super frame was $\hat{l}_{n-1,8}$,and the DC component of the LSF parameter for current encoding mode was $\bar{l}_n$ .Then the quantization of the LSF parameter could be described as follows:

Step1: Remove the DC component.

$$l'_n = l_n - \bar{l}_n . \tag{1}$$

Step2: Remove the inter-frame prediction.

$$\Delta l_n = l'_n - a_n \cdot \hat{l}_{n-1,8} . \tag{2}$$

Where a_n could be got offline to minimize the prediction error for the LSF parameters in the training speech lib as follows:

$$min\left(\sum_n \sum_{i=1}^{10} \left[l'_n(i) - \alpha(i) \cdot \hat{l}_{n-1,8}(i) \right]^2 \right). \tag{3}$$

Step3: Multi-stage vector quantization with inter-stage prediction would be used on the inter-frame prediction error. More details could be referenced to the paper [8]. The 400bps coder added two other stages to the codebook.

It should be pointed out that the $\hat{l}_{n-1,8}$ in the 400bps coder was got only using the first four stages like the 300bps coder.

Two gain parameters are calculated per frame for the encoder, i.e., 16 gains are obtained for each super-frame. The 16 gain parameters are vector-quantized using 8 bits for 300bps coder and 11 bits for 400bps coder, with a MSE criterion defined in the logarithmic domain. In the 300bps coder, the gain parameter was quantized using only one stage vector quantization with inter-frame prediction, while it would be quantized using two-stage vector quantization with inter-frame prediction in the

400bps coder. As mentioned above in the LSF quantization, the inter-frame prediction of the gain parameter in the 400bps coder would be got only using the core stage book, which was the first stage codebook in the gain quantization.

The pitch quantization was similar to the gain quantization but in the logarithmic domain. The quantizer structures for different parameters under both rates were given as Table 2.

Table 2. The quantizer structures for different parameters

Parameter	Vector Quantization Scheme	
	300bps	400bps
LSF	MSVQ(10, 8, 7, 6)	MSVQ(10, 8, 7, 6, 9)
Gain	VQ(8)	MSVQ(8, 3)
Pitch	VQ(10)	MSVQ(10, 6)

Principle of the Decoder

Four parameters would be unquantized in the decoder part and then used in the decoder based on the enhanced mixed excitation linear prediction model. The decoder used the periodic waveform or random series to represent the periodic or a periodic component of the excitation signal respectively. Then the excitation signal would be passed to the synthetic filter as well as the post filter to get the synthetic speech.

Test results and Conclusion

We have performed several intelligibility tests of the coder using Diagnostic Rhyme Test (DRT). In our tests, the score of the 300bps coder as well as the 400bps coder are 84% and 86% respectively. In addition, we do the MOS test on this embedded coder using P.862 tool and the result could be referenced to Table 3. The synthetic speech waveform and the original speech waveform could be seen as Figure 2.

Table 3. MOS test result

Test speech	MOS	
	300bps	400bps
Wav1.pcm	2.503	2.600
Wav2.pcm	2.442	2.561
Wav3.pcm	2.456	2.551
Wav4.pcm	2.450	2.553

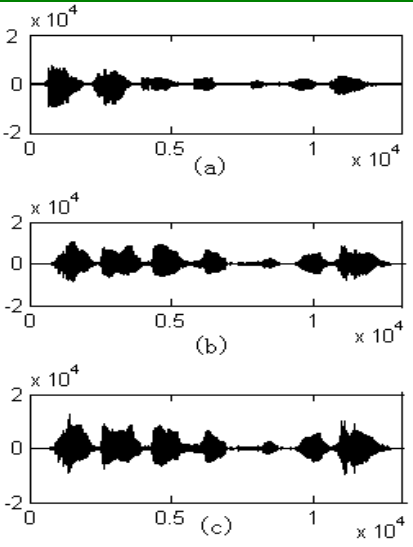

Fig.2. (a) original speech; (b) 300bps synthetic speech; (c) 400bps synthetic speech

Underwater speech communication could be used widely in utilizing the resource of the sea. The implementation of the reliable underwater speech communication was of great difficult because of the low channel rate as well as some other reasons.The embedded coder introduced in this paper could be used in the underwater speech communication. We have done the test in the pool and the whole system works well.

[a]email: malei1999@163.com

Keywords: Materialized View; Evolutionary Algorithm; Data Warehouse;

Abstract. Materialized view is an important topic in data warehouse research, and also affects the query efficiency and maintenance cost. The disk-space view-selection problem is to select a set of materialized views for the purpose of minimizing the total query processing cost and the total maintenance cost. In this paper we introduce evolutionary algorithm using stochastic ranking algorithm, which can enable materialized view selection under disk-space constraint. The algorithm improve the stochastic ranking algorithm, which can find a near-optimal feasible solution. This paper use the algorithm in Police data warehouse.

Introduction

Data warehouse is a subject-oriented, integrated, non-volatile and time-varying data sets, which is used to support decision-making managers. Most of queries are query integrated information in data warehouse, so which need spend a lot of time, in order to avoid accessing data sources and improve query speed, we access some intermediate results to the data warehouse in the process of query, these intermediate results which are stored in the data warehouse are called materialized views.

The aim of this paper is to the minimum cost of processing costs and maintenance cost in selecting materialized views. Currently, Many Algorithms are improved in this field, literature [1] proposed greedy algorithm, literature [2] proposed graph based on and or according to literature [1], these algorithms solved the problem of selection of materialized views, but these algorithms cannot solve the problem when the count of views is over 256. Many improved algorithms[6-9] are proposed in these years.This paper improves the improved algorithm by using random permutation algorithm and improved evolutionary algorithm, the improved algorithm can select materialized view when data warehouse has many views, the cost of selection is linear, which can get the best solution on selection of materialized view.

Basic Concepts and Theorems

Definition 1 Let G be a directed acycline graph. The graph has directed edges and no acycline.

Definition 2 Let qi and qj be query, if the query qi get answer by the use of the results of the query qj, then we call that qi depends on qj, denoted as $qi \leq qj$.

Definition 3 Directed acyclic graph G = (V, E), V represents views in data warehouse, edge $vi \rightarrow vj \in E$ if and only if $vj \leq vi$ and $\neg\exists vk$,satisfies $vj \leq vk \wedge vk \leq vi$, where $vi \neq vk \neq vj$.

For example, a fact table: Suspects table, three dimension tables: Time table, Education table and Case table. Relational model as follows:

Suspects (ID, TID, EID, CID)

Time(TID,Day,Month,Year)

Education(ID,Code,Name)

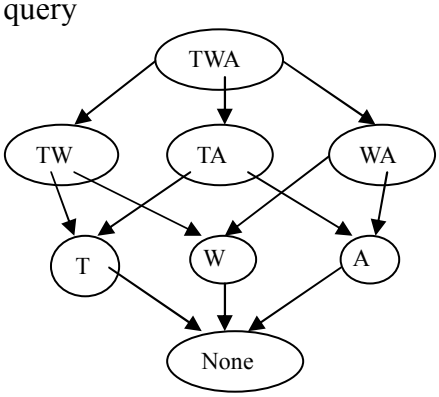
Case(CID,Code,Name)

Based on the above directed acyclic graph structure G=(V, E), where T, W, A respectively represent time dimension, education dimension and case dimension, the directed acyclic graph as shown in Figure 1. Each node in graph represents a query or view in OLAP, for example, W represents the OLAP query of the number of each education's suspects, WA represents the OLAP query of the number of each case's suspects.

In addition, the node and edge in the directed acyclic graph G = (V, E) respectively have the following different weights, Node v∈ V has three rights:

R_v: the size of node v

Q_v: the frequency of node v's query



U_v: v node update frequency

Figure 1 Directed Acyclic Graph

Edge (v, u)∈ E has two weights:

Q (v, u):the cost of querying node u by use of node v

U (v, u):the cost of maintenance node u by use of node v

In this paper, the following assumptions:

1. If v≤u, then $R_u \geq R_v$;
2. Update frequency of each node U_v is equal;
3. The maintenance cost U (v, u) of node u is one-tenth of view R_u's size;
4. The query cost Q (v, u) of node u is smaller than the size Rv of view v.

Let M be a materialized view, M⊆V, q (v, M) represents the minimum query cost,m(v,M) represents the minimum maintenance cost. So all cost C(G,M) with m (v, M) consideration in the selection of storage space constraint materialized view is to choose a set of views M to materialized, so the sum of the cost of maintaining materialized views query processing costs and the minimum total cost of overhead is represented by C (G, M), it the formula is:

$$C(G,M)=\sum_{v\in V} Q_v * q(v,M) + \sum_{v\in M} U_v * m(v,M)$$

Selection Algorithm of Materialized Views

A. Relation Knowledge of the Algorithm

(1)Objective function and penalty function

Materialized view selection under disk-space constraint is to select materialized view set, the cost of querying and maintenance is minimum and the performance is best. So that we can define the objective function is the total consideration overhead function C(G, M), defined as follows:

f (x) = C (G, Mx) where they meet S (Mx) ≤ S

Penalty function is defined as:

Φ (x) = max {S (Mx)-S, 0}

(2) Improved random order algorithm

Randomly arranged in the process, because this sort requires 2P individuals, but at last only need p individuals, so the number of cycles of outer loop need not more than P times, and the inner loop does not need to compare 2P-1 times, by using the principle of bubble sort, the first end of the cycle, you need to compare 2P-1 times, the best of the program into the front, while the second end of the cycle, you need to compare 2P-2 times the second best solution into the queue in front of the second position, so that in turn implemented. And when N> P, P last just a plan, so the outer layer of up to P times just do it.

Literature [7] need N times to sort randomly in outer loop and need 2P-1 times in inner loop. So the complexity of the literature [7] is N*(2P-1) in the worst case, and the complexity of the

improved algorithm is min (N, P) * (2P-1) / 2 in the worst case, so the complexity of the improved algorithm is improved to 1/2.

B. Algorithm decription

The algorithm uses the improved random sorting algorithm and a hybrid of the original algorithm which made some improvements since the original hybrid algorithm to elect two individuals hybridization, so that the algorithm could lead to cycles do after hybridization individuals may have only two, so in the randomly selected individuals, plus a limiting condition, ask for no two individuals are hybrids, so as to ensure that after cycles, generate new P individual makes a good program to get a good reproduction. The algorithm adopts Mutation algorithm which is the same as literature [4] and literature [5].

In each iteration of this algorithm, the first to use crossover operator, makes a good breeding executable program well, generate better individuals; followed by mutation algorithm that can produce before the new group does not exist individuals, so you can verify each of the search space of possible solutions; then calls random sorting algorithm to group the new group and mutation produced a new generation of hybrid solutions put together sort, after sorting, good executable program on the front row in the queue, programs or unenforceable bad came in the back of the queue, and finally remove the sorting queue before P individuals. This has been circulating executed until the termination condition is met.

Crossover Algorithm:

Input: the rate of Group Crossover Pc
output：Crossed Groups G′
repeat
Randomly select two individuals which are no crossover in G
$g_1=(a_1,a_2,\ldots,a_N)$, $g_2=(b_1,b_2,\ldots,b_N)$
select one number in U(0,1)
if u < Pc then
  for each bit i in individual do
    slect r randomly，r=0 or r=1
    if r=1 then
      set the bit i a_i in g_1'
      set the bit i b_i in g_2'
     else
      set the bit i b_i in g_1'
      set the bit i a_i in g_2'
    end if
  end for
else
  $g_1'= g_1$
  $g_2'= g_2$
end if
until i=P/2

Mutation Algorithm:

Input:Groups G Mutation rate Pm
Output：Mutated Groups G′
  for each individual in group do
    for each bit in individual do
      select one number u in U(0,1) randomly
      if u>Pm then
        if the bit is 1 then
          set bit 0
        else
          set bit 1
      end if
    end for
  end for

C. Algorithm example

This algorithm will be applied to the design of Police data warehouse, we select three dimensions in Figure 1 as example for analysis. According to the previous assumption, we give the corresponding weight to nodes and edges in graph. The size of table T, W, A respectively is: 0.2M, 0.03M, 0.1M. According to the assumption : If $v \leq u$, then there exists $R_u \geq R_v$, so the view size of TWA, TW, TA, WA is respectively: 5M, 0.8M, 5M, 6M, we assume that the update frequency of each view in graph is 0.05, the probability of the query view TWA, TW, TA, WA, T, W, A , respectively 0.6,0.3,0.5,0.3,0.2,0.1,0.2, the query cost of node u is less than the size R_v of view v, the maintenance cost of node u is equal the 0.1 size of view u. The storage space S is 0.7 times the constraints of space occupied by all views, $S = S=0.7*\sum_{v \in V} R_v$. Then S = 0.7 * 17.13M = 11.99M. Assuming P_c = 0.002, P_f = 0.4, P_m = 0.001. According to the above set value , the improved algorithm call improved evolutionary algorithm, the assumption of the first generation G(0) is (1110001), (1011111), (0110000), after hybridization and mutation G(3) is generated after the final (1011011) , (1010111) , (1000111) . Set (1011011) meet the cost constraints and the total cost of the minimum set of views , so the materialized views are TWA, TA, WA, W, A.

Conclusion

This paper studies the problem of selecting the data warehouse environment in the storage space constraint materialized views, materialized view selection will directly affect the efficiency of the data warehouse, has important significance. Based on the analysis of the data warehouse system of public security, get a directed acyclic graph, the use of random sorting algorithm using improved evolutionary algorithm, which is a collection of materialized view approximate optimal solution.

Review of Otsu Segmentation Algorithm

Yanxue DONG[1, a]

[1]School of Information, Linyi University, Linyi, 276000, China

[a]email: dyxtmb@163.com

Keywords: Otsu method;Image segmentation; Threshloding

Abstract. Image segmentation is the key step in the process from image processing to image analysis. Otsu method is one of the most successful methods for image thresholding because of its simple calculation. Otsu method can select threshold automatically and divide the object from the background in the image. In this paper, various Otsu algorithm are studied.

Introduction

Image segmentation is technologies and processes that put the image into a number of specific region that have unique nature and propose target of interest. It is one of the most basic problem of image analysis, it is very difficult because of the complex of images and it is an important part of the image processing. In computer vision, image segmentation is the process of converting an image into meaningful regions or objects . Image segmentation is widely applied such as locating tumors or other diseases, measuring volume of tissue, surgery navigated by computer, study on anatomy, objects recognition and so on.

Image segmentation is to subdivide the image into its region and object, according to two properties discontinuity and similarity, we divide the image segmentation methods into two categories and so the segmentation is categorized as segmentation based edge and segmentation based region. segmentation algorithms based on discontinuity of pixel are considered as the technology based on boundary or edge. Edge based segmentation attempts to detect the edges and pixels between the different regions where the pixels have rapid transition in intensity, extract the pixels connect to form a closed object region. The result of segmentation is a binary image. In theory, there are two main segmentation methods based on edge ,one based gray histogram and the other is gradient-based . Region based segmentation algorithm is dividing an image into regions according to some criteria. Region based segmentation algorithm is to divide pixels into categories in which pixels have similar characteristics or properties such as color, intensity,texture e.g. Segmentation methods such as thresholding, region growth, region splitting and merging are all region based.

Thresholding is an technique widely used in image segmentation and its key point is to find an optimal threshold(a gray value) according to its gray-scale distribution which can be used to separate an image's object from its background. although it is easy for humans to separate object from complex background, finding a threshold to separate them is a very difficult task[2].

we usually consider the gray-scale histogram an efficient tool to develop image thresholing algorithms. Assuming T stands for the global threshold of an image, thresholding is to get a binary image by turning pixels below T to zero and pixes about T to one, if f(x,y) indicates an image, g(x,y) is binary image after thresholding, it can be defined as[1]:

$$g(x,y)=\begin{cases}1 & f(x,y)\geq T\\ 0 & f(x,y)<T\end{cases} \tag{1}$$

We define thresholding as:

$$T=M\left[x,y,p(x,y),f(x,y)\right] \tag{2}$$

Where T is the threshold, f (x, y) is the gray value of point (x, y) , p(x, y) denotes some local property of the point.

According to the number of threshold values we can divide threshloding methods into two types:

Global thresholding

When T depends only on f (x, y)(that is, the gray-scale values) and the value of T is only relates to the feature of pixels, this thresholding technique is called global thresholding.

1.Local thresholding

If T depends on f (x, y) and p(x, y), this thresholding is called local thresholding which divides an image into several sub regions, and chooses various thresholds T for each sub region [3].

Otsu method was proposed by a Japanese Scholar Otsu in 1979, it is kind of global thresholding method cause it depend only gray value of the image. Otsu method is simple and effective and so it is widely used[4].

The Otsu method separate an image according to a threshold T counted based a gray scale histogram. For it only consider the gray-level information which is one-dimensional, it can not obtain better segmentation result. And then two dimensional Otsu algorithms was proposed which considers gray-scale information as well as each pixel's spatial correlation information in the

Neighborhood. Experiments show that two-dimensional Otsu method can get better segmentation results when it is applied to noisy images.[8] Otsu algorithm include huge amount of calculation, so many people propose techniques which reduce time complex of computation and still maintain segmentation result. In [9], a fast recursive technique is proposed that can reduce computational time efficiently. Otsu method is better when it is used to divide general images, however, it uses exhaustive search to evaluate the criterion that make the between-class variance maximum. When the number of class in an image increases, the calculation of Otsu method becomes huge and it will take too much time to select multi-threshold[10].

Various Otsu algorithms

1. Improved Otsu Algorithms

In [4], one-dimensional Otsu algorithm is described. It is widely applied because of its simple calculation and stability. as mentioned above, one-dimensional Otsu method only consider the pixel's gray-level information without considering the pixel's spatial information, so it can not get satisfactory segmentation result. when histogram of the image has two peaks vary widely ,this method fails. one-dimensional can not give good segmentation effect when the two classes in an image are very unequal. In this paper, a new algorithm is proposed based on entropy which obtain better segmentation result than one-dimensional Otsu method.

2. Comparative Research on Image Segmentation Algorithm

In literature[5], the authors gives an overview of the main image segmentation algorithms and some characteristics of them. This paper considers that Otsu algorithm is a kind of region based segmentation algorithm, it has high complexity rate and its processing rate is slow, its segmentation result is stable and better. For that, to improve the efficiency, Otsu method should be combined with other algorithm.

3. Improved Otsu Based on Improved Histogram

In literature[6], a fast Otsu algorithm based on improved histogram is proposed, and it efficiently reduce the computation complexity of 1D and 2D Otsu algorithm. In this algorithm, we project the 2D histogram onto the diagonal and apply to 2D Otsu on that histogram and then finde the optical threshold. To validate this algorithm, images added by salt and pepper noise and Gaussian noise are used, the results shows that this algorithm greatly improves the computing speed of threshold and have better noise immunity for salt and pepper noise images, but the results of Gaussian noise images are not good.

4. Otsu and K-Means Method

In literature[7], this idea is proposed that the objective function of Otsu algorithmand it of K means method in multilevel thresholding is equal. They have the same criteria that minimize the within-class variance. Otsu applies to global thresholding and K means method is applicable in local thresholding. For Otsu algorithm, the gray scale histogram should be computed before the algorithm be run, but for K means, not need the histogram computation. The two method can both give good segmentation results but comparatively speaking, the segmentation results of K means method are better because Otsu method take more time and the complexity of the method is more.

Conclusion

Table 1. Comparation of various Otsu method

Paper	Method	Segmentation Result	Limitation
Otsu Thresholding Based on Improved Histogram	Improved histogram	Good	Good at salt and paper noise images but not good at Gaussian noise images.
Comparative Research on Image Segmentati Algorithm	Global thresholding	Good/ stable	High complexity/ low processing rate
Otsu and K-mean	Global optimal threshold	Good	Increased complexity and time
Image Segmentation Based on Improved Otsu Algorithm	Entropy based	Stable	When the global distribution of target image and background vary widely, the performance degrades.

Table 1 gives the comparation result of various Otsu methods studied in this paper, the results and limitation are analyzed as well. Because of its simplicity, Otsu algorithms has been widely applied. Because of the complexity of images, the Otsu algorithm may be combined with other algorithms for different images from different fields.

Keywords: transfer alignment, lever arm, misalignment, estimation, statistic, least square

Abstract. Large misalignment is unavoidable for subsystems which could be deployed randomly on the carriers such as shipborne aircrafts, AUV. Ordinary linear filtering algorithms don't converge fast and accurately in non-linear conditions. It's critical for the accuracy of the transfer alignment. In this paper, a new misalignment and gyroscope bias online estimation method based on angular velocity processing is presented. Sensor measurements of M-SINS and S-SINS will be recorded for a certain period. Misalignment and the gyroscope bias will be calculated from these measurements directly with non-linear least square algorithm. Trust region method with pre-conditioning, subspace and conjugate gradient are applied for faster converge and better accuracy. Simulation results demonstrate the effectiveness of the algorithm.

Introduction

Shipborne aircrafts, UAV (Unmanned aerial vehicle), AUV (autonomous underwater vehicle), etc., are playing a more important role nowadays. Transfer alignment is the most effective method for the initialization of the inertial navigation systems onboard those systems because of its rapidity and accuracy [1]. But such systems could be deployed randomly on the carrier. Large misalignment is unavoidable. Linear system model of the transfer alignment is no longer valid in such conditions.

Non-linear Kalman filter algorithms have been developed to deal with the non-linear equations. Those algorithms require the knowledge of the system model such as gyroscope noise, measurement noise, etc. This makes the sub-system difficult to be adaptive to different dynamic environment and carriers.

In this paper, misalignment estimation method based on non-linear least square is presented. Trust region method with subspace reduction and preconditioned conjugate gradient is applied to make the calculation simpler and faster. The effectiveness of the method is demonstrated by simulation results.

Misalignment estimation based on non-linear least squares algorithm

The gyroscope output curve of the S-SINS differs from the curve of M-SINS because of the misalignment, sensor error and measurement noise. This is described by Eq. (1).

$$\omega_s = C_m^s \cdot \omega_m + \varepsilon + \omega_r \quad \omega_s = C_m^s \cdot \omega_m + \varepsilon + \omega_r \tag{1}$$

where C_m^s is the attitude transformation matrix from M-SINS to S-INS; ω_m, ω_s are the angular velocity outputs of the M-SINS and S-SINS, δK is the gyroscope scale factor error, ε is the gyroscope bias, ω_r is the random walk noise.

The gyroscope scale factor error could be neglected when gyroscopes better than tactical grade ($\delta K \le 100\,ppm$, $\varepsilon < 0.1°/h$, $\omega_r \le 0.01°/\sqrt{h}$) are applied and the angular velocity ω_m of the carrier reach a level of $0.1°/s$, the Eq. (1) could be simplified for least squares estimation:

$$\omega_s = C_m^s \cdot \omega_m + \varepsilon + \omega_r \tag{2}$$

Define:

$$f(\theta,\varepsilon)=\omega_s-C_m^s\cdot\omega_m-\varepsilon \tag{3}$$

where

$$C_m^s=\begin{bmatrix}\cos\gamma\cos\psi+\sin\gamma\sin\psi\sin\theta & -\cos\gamma\sin\psi+\sin\gamma\cos\psi\sin\theta & -\sin\gamma\cos\theta\\ \sin\psi\cos\theta & \cos\psi\cos\theta & \sin\theta\\ \sin\gamma\cos\psi-\cos\gamma\sin\psi\sin\theta & -\sin\gamma\sin\psi-\cos\gamma\cos\psi\sin\theta & \cos\gamma\cos\theta\end{bmatrix} \tag{4}$$

It can be seen that the frame transformation matrix C_m^s is nonlinear. To estimate the misalignment and the gyroscope bias error, define the target function:

$$\mathrm{F}(\theta,\varepsilon)=\min\sum_{i=1}^{m}f(\theta,\varepsilon)^2 \tag{5}$$

Figure (1) illustrates the simulated target function value according to the pitch and roll angle. It can be seen that if the pitch and roll equal the true misalignment angle, the target function will approach the global optimal value.

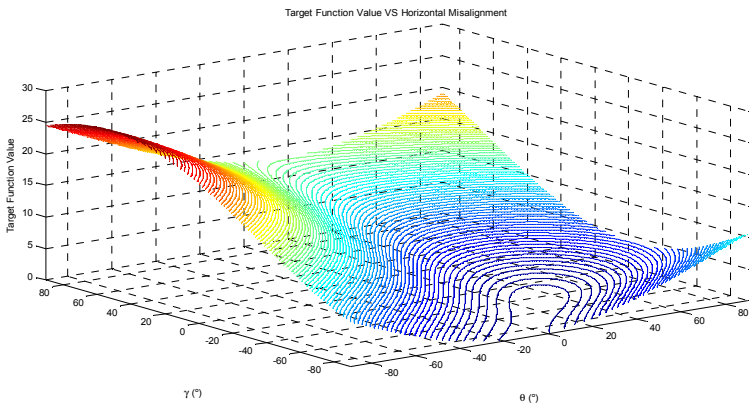

Fig. 1 M-SINS and S-SINS angular velocity amplitude and amplitude difference.

So the problem described in Eq. (5) could be treated like unconstrained minimization problem:

$$\min f(\mathrm{x}):\Re^n\to\Re \tag{6}$$

where it is assumed that f is twice continuously differentiable. The objective function could be rearranged with the form of Eq. (7):

$$F(\mathrm{x}+\mathrm{s})\approx\mathrm{F}(\mathrm{x})+\mathrm{g}^T s+\frac{1}{2}s^T Hs \tag{7}$$

where g is the gradient of F , H is the hessian matrix of F and H is positive symmetric.

Trust region algorithm [2]~[4] is applied to solve the problem described by Eq. (5):

Step 0 Define $0\le\eta_1\le\eta_2<1$, $0<\tau_1<1<\tau_2$, $0\le\varepsilon\le1$. $x_0\in\mathbb{R}^n$ .Set the upper bound of $\tilde{\Delta}>0$, initial trust region radius $\Delta_0\in(0,\tilde{\Delta}]$ and $k:=0$.

Step 1 if $\|\nabla f(x_k)\|\le\varepsilon$, break

Step 2 solve $\min q_k(d_k)=\nabla f(x_k)^T d_k+\frac{1}{2}d_k^T B_k d_k$, $\|d_k\|\le\Delta_k$, where B_k is the k^{th} approximation of Hessian matrix

Step 3 Compute $\Delta q_k = q_k(0) - q_k(d_k)$, $\Delta f_k = f(x_k) - f(x_k + d_k)$, $r_k = \frac{\Delta f_k}{\Delta q_k}$

Step 4 Update trust region radius:

$$\Delta_{k+1} := \begin{cases} \tau_1 \Delta_k & r_k \le \eta_1 \\ \Delta_k & \eta_1 \le r_k \le \eta_2 \\ \min\{\tau_2 \Delta_k, \tilde{\Delta}\} & r_k \ge \eta_2, \|d_k\| = \Delta_k \end{cases}$$

Step 5 if $r_k > \eta_1$, $x_{k+1} = x_k + d_k$, update B_k to B_{k+1}, $k = k+1$, go to Step 1; else $x_{k+1} = x_k$, $k = k+1$, go to Step 2

Good algorithms have been developed to solve the trust region problems more effectively. Subspace and conjugate gradient method are implemented to improve efficiency of the algorithm.

Dimension reduction:

It normally takes a long time to calculate the trust region sub-problem. Subspace reflection is an effective method to reduce the calculation work [5]-[7]. As is described in Eq.(8), the target function is reduced in 2 dimensional subspace.

$$D_k \overset{def}{=} span\{v_1, v_2\}, \text{where } v_1 = \frac{d_k}{\|d_k\|}, v_2 = \frac{g_k}{\|g_k\|} - v_1(v^T{}_1 \frac{g_k}{\|g_k\|}) \tag{8}$$

Normally the estimation is calculated with thousands of data points. With subspace method, the calculation load will be reduced significantly.

Conjugate gradient

The Hessian matrix is second derivative matrix, so the computation cost is extremely high. To avoid Hessian matrix calculation, conjugate gradient algorithm [8]-[11] is applied. Search direction is calculated with Eq. (9).

$$d_k = \begin{cases} -g_k & k = 0 \\ -g_k + \beta_{k-1} d_{k-1} & k \ge 1 \end{cases} \tag{9}$$

$$\beta_k = \frac{r_{k-1}^T z_{k-1}}{r_{k-2}^T z_{k-2}} \tag{10}$$

$$r_k = r_{k-1} - \frac{r_{k-1}^T z_{k-1}}{d_k^T H d_k} H d_k \tag{11}$$

where $Pz_k = r_k$, P is precondition matrix for H and $P = R^2 = A^T A$, A is Jacobian matrix of $f(x)$.

Misalignment estimation

To estimation the misalignment from the sensor measurements, algorithm with the following workflow is implemented.

Step 0 Initialize the target function $F(x)$, set the start point x_0, define $0 \le \varepsilon \le 1$.

Step 1 Calculate the gradient g and the Jacobian matrix A.

Step 2 Calculate the QR factorization of the $A^T A$, $A_k{}^T A_k = Q_k R_k$

Step 3 Calculate and apply the pre-conditioner to gradient g, $z_k = -R_k \backslash R_k{}^T \backslash g_k$.

Step 4 Calculate the conjugate gradient with FR method, Eq. (9)~Eq.(11).

Step 5 Calculate the reflecting subspace with Eq. (8)

Step 6 Solve the Trust Region sub problem to acquire the Step vector:

$min\{\tilde{g}^T s_k + \frac{1}{2} s_k{}^T \tilde{H} s_k, \| s_k \| \leq \Delta\}$, where $\tilde{g} = g \cdot D_k$, $\tilde{H} = D_k{}^T A^T A D_k$.

Step 7 Adjust the Trust region radius:

$$\Delta_{k+1} := \begin{cases} \tau_1 \Delta_k & r_k \leq \eta_1 \\ \Delta_k & \eta_1 \leq r_k \leq \eta_2 \\ \min\{\tau_2 \Delta_k, \tilde{\Delta}\} & r_k \geq \eta_2, \|d_k\| = \Delta_k \end{cases}$$

Step 8 Update the target function F(x), if $F(x_k + \mathrm{s}) < F(x_k)$, update the Step $x_{k+1} = x_k + s$. Go to Step 1.

The complete workflow is described by Figure 2.

Simulation conditions

The signal to noise ratio (SNR) of the measurement is motion intensity related. To evaluate the effectiveness of the algorithm in tougher conditions, shipborne implementation is simulated.

Assuming that, a surface vessel was traveling in normal sea state. The wind wave will cause pitch, roll, surge, sway and heave of the vessel. These motions are considered as periodical cosine form signals in the simulation. Parameters used in the simulation are listed in Table 1.

Table 1 Parameters used to calculate heading, pitch and roll

	Heading	Pitch	Roll
Amplitude	2°	7°	10°
Period	60 s	5 s	6 s

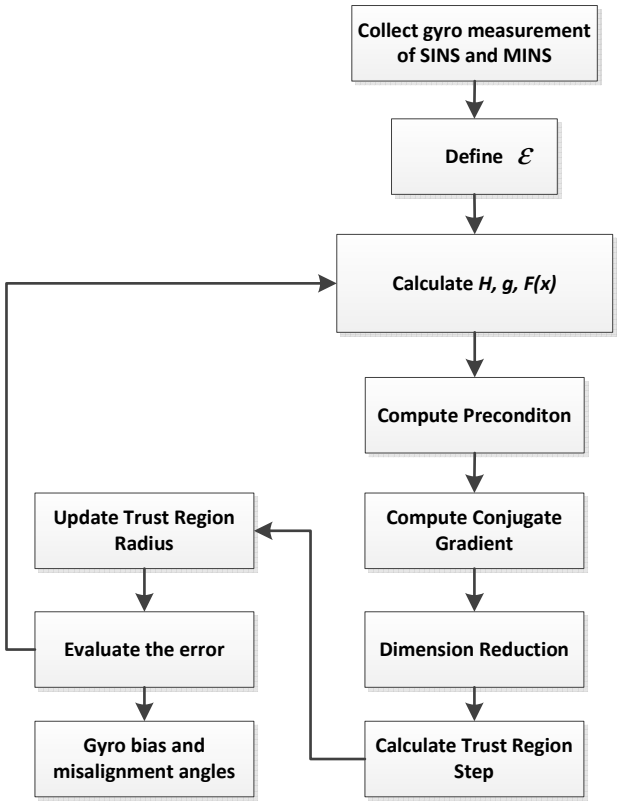

Fig. 2 Misalignment estimation workflow

The M-SINS is normally 1 or 2 grade more accurate than the S-SINS. In the simulation, the error of the M-SINS is ignored. 3 different gyroscope bias errors were simulated. Parameters are listed in Table 2.

Table 2 Sensor accuracy of the S-SINS

	Simulation 1	Simulation 2	Simulation 3
ε_x ($^\circ/h$):	10.5	1.0	0.1
ε_y ($^\circ/h$):	9.5	1.5	0.2
ε_z ($^\circ/h$):	11	2.0	0.3
Random walk ($^\circ/\sqrt{h}$)	10.0	1.0	0.1

To simulate the flexure of the ship deck, a second order Markov process is setup:

$$\ddot{\varphi} + 2\beta\dot{\varphi} + \beta^2\varphi = \eta \tag{12}$$

where φ is the flexure angle and $\varphi = [\varphi_x \quad \varphi_y \quad \varphi_z]^T$ its variance $\sigma = [\sigma_x \quad \sigma_y \quad \sigma_z]^T$; $\eta = [\eta_x \quad \eta_y \quad \eta_z]^T$ is Gaussian while noise and has a variance of $Q = [Q_{\eta x} \quad Q_{\eta y} \quad Q_{\eta z}]^T$, $\beta = [\beta_x \quad \beta_y \quad \beta_z]^T$ is constant.

Q, η, σ and β have the following relation：

$$Q_\eta = 4\beta^3\sigma^2 \tag{13}$$

In the simulations, set $\beta = [7 \quad 8 \quad 9]^T$, 2 different flexure conditions are simulated:

Table 3 Flexure condition parameters

	$\sigma_x(''/s)$	$\sigma_y(''/s)$	$\sigma_z(''/s)$
Flexure Condition 1	0.4	0.5	0.6
Flexure Condition 2	4	5	6

Simulation results

The sampling period of the sensor is 0.005s. Sensor data of 150 seconds is collected and processed to estimate the misalignment and gyroscope bias. The simulation results are listed in table 4~5. The iteration steps under flexure condition 1 are illustrated in figure 3~5.

The simulation results demonstrate that random misalignment could be estimated effectively with the algorithm. The flexure of the carrier will affect the gyroscope bias estimation accuracy.

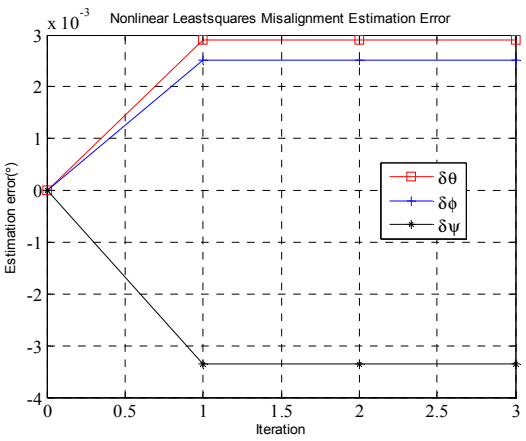

Fig. 3 Non-linear least square interation steps with true value [0,0,0]

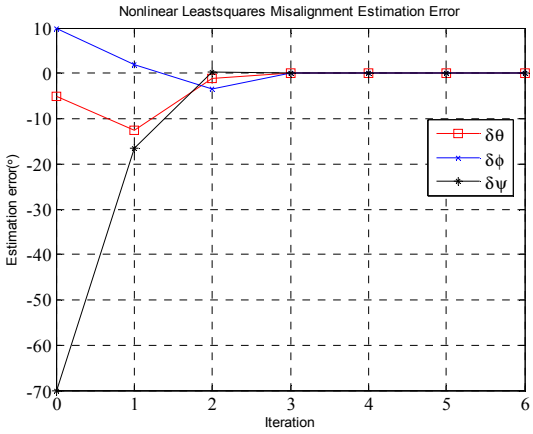

Fig. 4 Non-linear least square interation steps with true value [5,-10,-70]

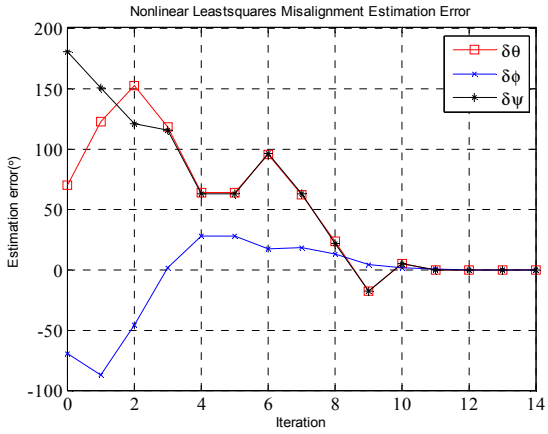

Fig. 5 Non-linear least square interation steps with true value [-70,70,180]

is presented. The estimation requires only gyro scope measurements of the M-SINS and S-SINS. Pre-conditioning, conjugate gradient and subspace technique are implemented to improve the trust region calculation efficiency. Simulation results demonstrate that the large misalignment could be estimated with the method presented in the paper. Gyroscope bias error could be also estimated. But it's sensitive to carrier flexure. Further research would be focused on new sensor bias error adaptive to the carrier flexure.

The method is aimed to estimate the static part of the misalignment and gyroscope bias error in transfer alignment. The dynamic parts could be added to a Kalman filter state vector to improve the alignment accuracy.

Estimation using sensor measurements could avoid the error crossing over the iterations. The data from M-SINS and S-SINS should be collected and processed simultaneously. This requires either a hard-wired connection or RF radio transmission between the M-SINS and the S-SINS. To implement the application in random position, the wireless tactical data link (TDL) such as Carrier Aircraft Inertial Navigation System (CAINS) based on Link-4A communication system is required. The synchronization of the data is also critical. Time mark should be added to the communication protocol. Reference information delay could also be estimated with similar principle [12]

Key words: formal solution, reaction diffusion, singular perturbation, time delay.

Abstract: The singularly perturbed systems for the nonlinear three-species food-chain reaction systems with time delay are considered. By using the method of the stretched variable, the formal asymptotic solution is obtained under suitable conditions.

1. Introduction

The nonlinear singularly perturbed problem is a very attractive study object in international academic circles [1]. Recently, approximate methods have been developed and refined, including the averaging method, the boundary layer method, the matched asymptotic expansion method, and the multiscale method. Many scholars have done a great deal of work [2-7]. However, few of them have studied the nonlinear singularly perturbed with time delay. In view of this, we study the following singularly perturbed systems with diffusion and time Delay.

$$\varepsilon \partial u_1 / \partial t - L_1 u_1 = f_1(u_1(t-\varepsilon r))(\lambda_1 - r_{11}u_1 - r_{21}u_2 - r_{31}u_3), \quad (t,x) \in (0,T]\times\Omega, \tag{1}$$

$$\varepsilon \partial u_2 / \partial t - L_2 u_2 = f_2(u_2(t-\varepsilon r))(\lambda_2 - r_{22}u_2 + r_{12}u_1 - r_{32}u_3), \quad (t,x) \in (0,T]\times\Omega, \tag{2}$$

$$\varepsilon \partial u_3 / \partial t - L_3 u_3 = f_3(u_3(t-\varepsilon r))(\lambda_3 - r_{33}u_3 + r_{13}u_1 + r_{23}u_2), \quad (t,x) \in (0,T]\times\Omega, \tag{3}$$

with the boundary and initial conditions

$$Bu_i = u_i + \alpha_i(x)\frac{\partial u_i}{\partial n} = g_i(x), \quad a_i(x) \ge a_0 > 0, x \in \partial\Omega, i = 1,2,3, \tag{4}$$

$$u_i = h_i(t,x,\varepsilon) \quad t \in [-\varepsilon r, 0] \quad i = 1,2,3 \tag{5}$$

where ε is a positive small parameter, r is a positive constants, $r\varepsilon$ is a time delay, $u_1(t,x)$, $u_2(t,x)$ and $u_3(t,x)$ stand for the numbers of interacting species, respectively. $x \equiv (x_1, x_2, \cdots, x_n) \in \Omega$, and Ω is a bounded domain in R^n with boundary $\partial\Omega$, $\partial / \partial n$ denotes the outward normal derivative on $\partial\Omega$.The above problems (1)-(5) arise from a simple food-chain model describing three interacting species in a spatial habitat Ω [8-9]. The real number λ_i is the net birth rate of the i-th species, and r_{ij} are the density coefficients of the prey and predator populations, respectively. L_i is a uniformly elliptic operator in the form

$$L_i u = -\sum_{j,k=1}^{N} a_{j,k}^{(i)}(x,t)\frac{\partial^2 u}{\partial x_j \partial x_k} + \sum_{j=1}^{N} b_j^{(i)}(x,t)\frac{\partial u}{\partial x_j}, \quad (i = 1, 2, 3). \tag{6}$$

2. Outer Solution

Firstly, we need the following hypotheses:

(H1) There exists a positive number γ such that for any $\xi=(\xi_1,\cdots,\xi_N)\in R^N$, $(x,t)\in\overline{\Omega}\times[0,\omega]$ and $i\in\{1,2,\cdots,m\}$, we have

$$\sum_{j,k=1}^{N} a_{jk}^{(i)}(x,t)\xi_j\xi_k \geq \gamma|\xi|^2 ,$$

(H2) $a_{j,k}^{(i)}(x,t), b_j^{(i)}(x,t), \alpha_i(t)$, $g_i(t)>0$, and $h_i(t,x,\varepsilon)>0$ with respect to variables are Holder continuous in correspondence ranges and $g_i(x)=h_i(x), i=1,2,3$ as $x\in\partial\Omega$.

(H3) $f_i(y)\ (i=1,2,3)$ is continuous differential positive functions.

In view of the biological significance of $u_i(x,t), i=1,2,3$, we have $0\leq u_i(x,t)\leq M_i$, where M_i denotes the environmental carrying capacity.

The reduced problem of the equations (1)-(5) is

$$-Lu_1 = f_1(u_1)(\lambda_1 - r_{11}u_1 - r_{21}u_2 - r_{31}u_3), \tag{7}$$

$$-Lu_2 = f_2(u_2)(\lambda_2 - r_{22}u_2 + r_{12}u_1 - r_{32}u_3), \tag{8}$$

$$-Lu_3 = f_3(u_3)(\lambda_3 - r_{33}u_3 + r_{23}u_2 + r_{13}u_1), \tag{9}$$

$$Bu_i = g_i(x), \qquad x\in\partial\Omega, i=1,2,3. \tag{10}$$

We also assume that the equations (7)-(10) have a positive solution $U_0=(U_{10},U_{20},U_{30})$.

Let the outer solution of the equations (1)-(4) are as follows

$$U_i \sim \sum_{j=0}^{\infty} U_{ij}(x)\varepsilon^j, \quad i=1,2,3. \tag{11}$$

Thus, substituting U_i into Equations (1)-(4), we obtain

$$-L_1U_1 = f_1(U_1)(\lambda_1 - r_{11}U_1 - r_{21}U_2 - r_{31}U_3), \quad x\in\Omega, \tag{12}$$

$$-L_2U_2 = f_2(U_2)(\lambda_2 - r_{22}U_2 + r_{12}U_1 - r_{32}U_3), \quad x\in\Omega, \tag{13}$$

$$-L_3U_3 = f_3(U_3)(\lambda_3 - r_{33}U_3 + r_{13}U_1 + r_{23}U_2), \quad x\in\Omega, \tag{14}$$

$$BU_i = U_i + \alpha_i(x)\frac{\partial U_i}{\partial n} = g_i(x), \quad a_i(x)\geq a_0>0, x\in\partial\Omega, i=1,2,3, \tag{15}$$

Developing $f_i(U_i), i=1,2,3$ in ε, we have

$$f_i(U_i)\equiv F_i(\varepsilon)\sim\sum_{j=0}^{\infty}F_{ij}\varepsilon^j , \tag{16}$$

where $F_{i0}=f_i(U_{i0})$, $F_{ij}=\dfrac{1}{j!}\dfrac{\partial^j F_i}{\partial\varepsilon^j}\Big|_{\varepsilon=0} = f_{iu_i}(U_{i0})U_{ij}+f_{ij}, j=1,2,3\cdots$. It is obvious that f_{ij} are determined functions successively. Comparing the same coefficients of ε^j for equations, we obtain

$$-L_1U_{1j} = \lambda_1F_{1j} - r_{11}\sum_{m,n=0}^{m+n=j}F_{1m}U_{1n} - r_{21}\sum_{m,n=0}^{m+n=j}F_{1m}U_{2n} - r_{31}\sum_{m,n=0}^{m+n=j}F_{1m}U_{3n} \tag{17}$$

$$-L_2U_{2j} = \lambda_2F_{2j} - r_{22}\sum_{m,n=0}^{m+n=j}F_{2m}U_{2n} - r_{12}\sum_{m,n=0}^{m+n=j}F_{2m}U_{1n} - r_{33}\sum_{m,n=0}^{m+n=j}F_{2m}U_{3n} \tag{18}$$

$$-L_3U_{3j} = \lambda_3F_{3j} - r_{33}\sum_{m,n=0}^{m+n=j}F_{3m}U_{3n} + r_{13}\sum_{m,n=0}^{m+n=j}F_{3m}U_{1n} + r_{23}\sum_{m,n=0}^{m+n=j}F_{3m}U_{1n} \tag{19}$$

$$BU_{ij} = g_{ij} \tag{20}$$

where $g_{ij}=\frac{1}{j!}\left[\frac{\partial^j g_i}{\partial \varepsilon^j}\right]_{\varepsilon=0}$, $j=1,2\cdots$. From the linear problems (17)-(20), we can solve $\left(U_{1j},U_{2j},U_{3j}\right), j=1,2,3,\cdots$ successively, and noting that U_0 satisfies the problems (7)-(10), we obtain the outer solution $U_i,(i=1,2,3)$ for the original problem (1)-(4). But it may not satisfy the initial condition (5), so that we need to construct the time delay initial layer functions $\left(V_1,\mathrm{V}_2,\mathrm{V}_3\right)$.

3. Formal Solution

Now we first introduce a stretched variable

$$\tau=\frac{t}{\varepsilon},\ 0<\varepsilon\ll 1 \tag{21}$$

And let $u_i=U_i\left(x,\varepsilon\right)+V_i\left(\tau,x,\varepsilon\right), i=1,2,3$. Substituting them into Equations (1)-(5), we have

$$\partial V_1/\partial\tau-L_1V_1=f_1(\mathrm{U}_1+V_1(t-\varepsilon r))(\lambda_1-r_{11}(U_1+V_1)-r_{21}(U_2+V_2)-r_{31}(U_3+V_3))-f_1(\mathrm{U}_1)(\lambda_1-r_{11}U_1-r_{21}U_2-r_{31}U_3), \tag{22}$$

$$\partial V_2/\partial\tau-L_1V_2=f_2(\mathrm{U}_2+V_2(t-\varepsilon r))(\lambda_2-r_{22}(U_2+V_2)+r_{12}(U_1+V_1)-r_{32}(U_3+V_3))-f_2(\mathrm{U}_2)(\lambda_2-r_{22}U_2+r_{12}U_1-r_{32}U_3), \tag{23}$$

$$\partial V_3/\partial\tau-L_1V_3=f_3(\mathrm{U}_3+V_3(t-\varepsilon r))(\lambda_3-r_{33}(U_3+V_3)+r_{13}(U_1+V_1)+r_{23}(U_2+V_2))-f_3(\mathrm{U}_3)(\lambda_3-r_{33}U_3+r_{13}U_1+r_{23}U_2), \tag{24}$$

$$BV_i=0\quad x\in\partial\Omega, i=1,2,3, \tag{25}$$

$$V_i=h_i-U_i\quad t\in\left[-\varepsilon r,0\right]\quad i=1,2,3. \tag{26}$$

Let

$$V_i\sim\sum_{j=0}^{\infty}V_{ij}\left(\tau,x\right)\varepsilon^j,\quad i=1,2,3, \tag{27}$$

$$f_i(\mathrm{U}_i+V_i\left(t-\varepsilon r\right))-f_i(\mathrm{U}_i)\equiv\overline{F_i}\left(\varepsilon\right)\sim\sum_{j=0}^{\infty}\overline{F_{ij}}\varepsilon^j, i=1,2,3, \tag{28}$$

$$f_i(\mathrm{U}_i+V_i\left(t-\varepsilon r\right))\equiv\overline{G_i}\left(\varepsilon\right)\sim\sum_{j=0}^{\infty}\overline{G_{ij}}\varepsilon^j, i=1,2,3, \tag{29}$$

where

$$\overline{F_{i0}}=f_i(\mathrm{U}_{i0}+V_{i0}\left(t-\varepsilon r\right))-f_i(\mathrm{U}_{i0})=f_{u_i}\left(\mathrm{U}_{i0}+\theta_iV_{i0}\left(t-\varepsilon r\right)\right)V_{i0}\left(t-\varepsilon r\right),0<\theta_i<1,$$

$$\overline{F_{ij}}=\frac{1}{j!}\frac{\partial^j\overline{F_{ij}}}{\partial\varepsilon^j}\bigg|_{\varepsilon=0}=f_{iu_i}\left(U_{i0}+V_{i0}\left(t-\varepsilon r\right)\right)V_{ij}\left(t-\varepsilon r\right)+\overline{f_{ij}}, i=1,2,3,\ j=1,2,3,\cdots,$$

$$\overline{G_{i0}}=f_i(\mathrm{U}_{i0}+V_{i0}\left(t-\varepsilon r\right)),$$

$$\overline{G_{ij}}=\frac{1}{j!}\frac{\partial^j\overline{G_i}}{\partial\varepsilon^j}\bigg|_{\varepsilon=0}=f_i(\mathrm{U}_i+V_i)-f_{iv_i}(\mathrm{U}_i+V_i)\varepsilon r+\frac{1}{2!}f^{"}_{iv_i}(\mathrm{U}_i+V_i)\left(\varepsilon r\right)^2+\cdots.$$

Substituting equations (27)-(29) into equations (22)-(26), developing f_i in ε, and comparing the same coefficients of ε^j for equations, we have

$$\begin{aligned}\left(V_{1j}\right)_\tau-L_1V_{1j}=&\left(\lambda_1\overline{F_{1j}}-r_{11}\sum_{m,n=0}^{m+n=j}\overline{F_{1m}}U_{1n}-r_{21}\sum_{m,n=0}^{m+n=j}\overline{F_{1m}}U_{2n}-r_{31}\sum_{m,n=0}^{m+n=j}\overline{F_{1m}}U_{3n}\right)\\&-\left(r_{11}\sum_{m,n=0}^{m+n=j}\overline{G_{1m}}U_{1n}+r_{21}\sum_{m,n=0}^{m+n=j}\overline{G_{1m}}U_{2n}+r_{31}\sum_{m,n=0}^{m+n=j}\overline{G_{1m}}U_{3n}\right),\end{aligned} \tag{30}$$

$$\left(V_{2j}\right)_\tau-L_2V_{2j}=\left(\lambda_2\overline{F_{2j}}-r_{22}\sum_{m,n=0}^{m+n=j}\overline{F_{2m}}U_{2n}+r_{12}\sum_{m,n=0}^{m+n=j}\overline{F_{2m}}U_{1n}-r_{32}\sum_{m,n=0}^{m+n=j}\overline{F_{2m}}U_{3n}\right)$$

$$+\left(-r_{22}\sum_{m,n=0}^{m+n=j}\overline{G_{2m}}U_{2n}+r_{12}\sum_{m,n=0}^{m+n=j}\overline{G_{2m}}U_{1n}-r_{32}\sum_{m,n=0}^{m+n=j}\overline{G_{2m}}U_{3n}\right), \tag{31}$$

$$\left(V_{3j}\right)_{\tau}-L_3V_{3j}=\left(\lambda_3\overline{F_{3j}}-r_{33}\sum_{m,n=0}^{m+n=j}\overline{F_{3m}}U_{3n}+r_{13}\sum_{m,n=0}^{m+n=j}\overline{F_{3m}}U_{1n}+r_{23}\sum_{m,n=0}^{m+n=j}\overline{F_{3m}}U_{2n}\right)$$

$$+\left(-r_{33}\sum_{m,n=0}^{m+n=j}\overline{G_{3m}}U_{3n}+r_{13}\sum_{m,n=0}^{m+n=j}\overline{G_{3m}}U_{1n}+r_{23}\sum_{m,n=0}^{m+n=j}\overline{G_{3m}}U_{2n}\right), \tag{32}$$

$$BV_{ij}=0,\ x\in\partial\Omega,\ i=1,2,3, \tag{33}$$

$$V_{ij}=h_{ij}-U_{ij},\ t\in\left[-\varepsilon r,0\right],\ i=1,2,3. \tag{34}$$

From the linear problems (30)-(34) when $j=0$, we can easily get $\left(V_{10},V_{20},V_{30}\right)$, then we can get $\left(V_{1j},V_{2j},V_{3j}\right),\ j=1,2,3\cdots$ when $j=1,2,3\cdots$ from (30)-(34). Thus, we obtain formal asymptotic expansion of solution for the Equations (1)-(5)

$$u_i\sim\sum_{j=0}^{\infty}\left(U_{ij}(x)+V_{ij}(\tau,x)\right)\varepsilon^j,\ i=1,2,3.$$

Keywords: DOA Estimation; Linear Canonical Transform; Root-MUSIC

Abstract. An algorithm of DOA estimation based on linear canonical transform is proposed. In this method, the observed signals are first transformed to linear canonical domain, through selecting appropriate transformation parameters, characteristics of the observed signal appear to be energy-concentrated in the corresponding linear canonical domain, and by that, the linear canonical domain steering vector is defined, then root-MUSIC is used to estimate DOA of impinging signals. Simulation examples are provided showing the effectiveness of the presented technique.

Introduction

Direction of arrival (DOA) estimation is widely used in radar, sonar, and communication systems. The technique plays an important role in enhancing the performance of wireless communications. Many DOA estimation algorithms have already been studied like root-MUSIC, Maximum Likelihood Estimation, Time-frequency MUSIC and so on[1-7]. These algorithms generally achieve high accuracy, but also have many deficiencies, such as only based on narrow band hypothesis, complex computation and only applicable for LFM signals.

The linear canonical transform (LCT) is an important time-frequency analysis tool, some scholars have done many works on it[8-11]. Comparing to the fractional Fourier transform and the Fourier transform, the LCT is more flexible for signal processing due to its four transform parameters. So a novel approach to direction finding of wideband time-frequency signals in LCT domain is introduced. By using linear canonical transform and the unique concentration signature of the wideband time-frequency signal in a certain linear canonical transform domain, the LCT domain time-invariant vector is given, and then, the signal DOA can be estimated by root-MUSIC[1]. Theoretical analysis and simulation results show that, this method can solve the DOA estimation problem of wideband time-frequency signal, and can obtain good estimating performance.

Array Signal Model and Problem Statement

Let a ULA of M sensors spaced d apart receive Gaussian pulse signals impinging from the K ($K<M$) unknown directions $\{\theta_k\}_{k=1}^{K}$. Suppose the reference point is the first unit, then the output of the ith sensor can be expressed as:

$$x_i(t)=\sum_{k=1}^{K}s_k(t-\tau_{ik})+n_i(t) \quad , \qquad i=1, 2\ldots M. \tag{1}$$

Where, $\tau_{ik}=\frac{(i-1)d}{c}\sin(\theta_k)$, $s_k(t)=e^{-(\frac{t}{p_k})^2}$, k=1, 2… K. $\{s_k(t)\}_{k=1}^{K}$ are source waveforms, $\{n_i(t)\}_{i=1}^{M}$ are the additive Gauss white noises. The source signals and the noises are assumed to be statistically independent. τ_{ik} is the path delay of the plane wave from the source. C is the light speed.

Combining (3) and (1), we obtain

$$x_i(t)=\sum_{k=1}^{K}e^{2t\tau_{ik}/p_k^2}e^{-\tau_{ik}^2/p_k^2}s_k(t)+n_i(t). \tag{2}$$

From (2), it can be seen that, the direction vector of the Gaussian pulse signals is associated with the direction θ_k and the time index t. So the DOA's of the Gaussian pulse signals cannot be estimated directly by root-MUSIC algorithm.

The Linear Canonical Transform

The linear canonical transform(LCT) is also known as the ABCD transform, generalized Fresnel transform and the Collins formula etc.. This transform proposed by Moshinsky and Collins is gradually attented in signal processing.

The LCT with parameters(a, b, c, d) of a signal $f(t)$ is defined as:

$$F_{(a,b,c,d)}(u)=L_{(a,b,c,d)}(f(t))=\begin{cases}\sqrt{\frac{1}{j2\pi}}\cdot e^{\frac{jd}{2b}u^2}\int e^{-\frac{j}{b}ut}e^{\frac{ja}{2b}t^2}f(t)dt, & b\neq 0;\\ \sqrt{d}\cdot e^{\frac{jcd}{2}u^2}f(du), & b=0.\end{cases} \tag{3}$$

Where, parameters(a, b, c, d) are real numbers satisfying $ad-bc=1$. The LCT is a unitary transform and has many special cases. Choosing appropriate parameters, the LCT coincides with the conventional Fourier transform(FT), the chirp multiplication operation, the fractional Fourier transform(FRFT) and the scaling operation etc..

The LCT has three free parameters. Comparing to the FT with no free parameter and the FRFT with one free parameters, the LCT is more flexible. The FRFT which has only one free parameter, can be interpreted as a rotation by an angle in the time-frequency plane, while the LCT with three free parameters has not only the rotation, but also the twisting and stretching in the time-frequency plane. By changing transform parameters, the LCT can easily change the shape and position of the signal time-frequency distribution. Therefore, we can prove that, for a given signal, when selecting suitable transform parameters, the LCT will result in the concentration of the signal energy in a certain LCT domain[8][11].

DOA Estimation in Linear Canonical Transform Domain

According to the definition of the LCT, we can obtain the LCT of the reference sensor output $s_k(t)$ as

$$s_{k1(a,b,c,d)}(u)=\sqrt{\frac{1}{j2\pi}}\,\mathrm{e}^{j\frac{d}{2b}u^2}\int_{-T/2}^{T/2}\mathrm{e}^{-\frac{j}{b}ut}e^{j\frac{a}{2b}t^2}e^{-\left(\frac{t}{p_k}\right)^2}dt=\sqrt{\frac{1}{j2\pi}}\,\mathrm{e}^{j\frac{d}{2b}u^2}\int_{-T/2}^{T/2}\mathrm{e}^{-\frac{j}{b}ut}e^{\left(j\frac{a}{2b}-\frac{1}{p_k^2}\right)t^2}dt \tag{4}$$

where T is the observed time of the signal.

From (4),it can be seen that, if $a/(2b)=1/jp_k^2$, the expression (4) can be expressed as

$$s_{k1(a,b,c,d)}(u)=\sqrt{\frac{1}{j2\pi}}\,\mathrm{e}^{j\frac{d}{2b}u^2}\,T\frac{\sin[(u/b)T/2]}{(u/b)T/2} \tag{5}$$

From the above expression, we can prove that, when $a/(2b)=1/jp_k^2$, $s_{k1(a,b,c,d)}(u)$ has the best energy-concentrated performance, and the peak of $s_{k1(a,b,c,d)}(u)$ is

$$s_{k1(a,b,c,d)}(u_{1m})=\sqrt{\frac{1}{j2\pi}}\,\mathrm{e}^{j\frac{d}{2b}u_{1m}^2}\,T. \tag{6}$$

Therefore, for a given signal, the LCT will result in the concentration of the signal energy in a certain LCT domain.

Through the same analysis, we know that, the LCT $s_{ki(a,b,c,d)}(u)$ of the *i*th sensor output $s_k(t-\tau_{ik})$ will still produce energy concentration when $a/(2b)=1/jp_k^2$, and the peak of $s_{ki(a,b,c,d)}(u)$ is

$$s_{ki(a,b,c,d)}(u_{im})=\sqrt{\frac{1}{j2\pi}}\,\mathrm{e}^{j\frac{d}{2b}u_{im}^2}\,e^{-\frac{\tau_{ik}^2}{p_k^2}}T=e^{j\frac{ad}{b}u_{1m}\tau_{ik}}s_{k1(a,b,c,d)}(u_{1m}) \quad . \tag{7}$$

Where , the time delay τ_{ik} is very small, and τ_{ik}^2 can be ignored.

Here, we define the LCT domain steering vector of the signal $s_k(t)$ as

$$\mathbf{A}_{(a,b,c,d)}=[1,\mathrm{e}^{j\frac{ad}{b}u_{1m}\tau_{2k}},\cdots,e^{j\frac{ad}{b}u_{1m}\tau_{Mk}}]^T. \tag{8}$$

The value of $\mathbf{A}_{(a,b,c,d)}$ is only associated with time delay, that is, it is only associated with the direction θ_k. So, we can use root-MUSIC algorithm to estimate the signal DOA in the corresponding LCT domain.

Simulation Results

To verify the predictions, an example of computer simulation is given. We assume a ULA of *M*=10 sensors and two Gaussian pulse sources $s_1(t)$ and $s_2(t)$ impinging from $\theta_1=20^o$ and $\theta_2=30^o$, the spacing of the array elements is $d=0.15m$. The frequencies of the Gaussian pulse $s_1(t)$ and $s_2(t)$ are 10kHz and 20KHz, the bandwidth and the sampling frequency of both signals are 60% and 1MHz. The data length is *N*=379 snapshots. At each level of the SNR, we run 100 Monte Carlo simulations, and the MSE's obtained are shown in Figure.1.

From Figure.1, it can be seen that, the proposed technique in this paper can accurately estimate the DOA's of the observed signals and has good estimating performance.

Conclusion

A new method based on LCT for estimating DOA of the wideband time-frequency signal is presented. In this method, the LCT domain time-invariant steering vector is defined by LCT and the concentration signature of the signal in the corresponding LCT domain, then, the root-MUSIC algorithm is used to estimate the DOA of the signal. Theoretical analysis and simulation results show that, this approach is not only to solve the DOA estimation problem of wideband time-frequency signal, and can obtain good estimating performance. Due to the high degree of flexibility and broad applicability, this method greatly enriches the DOA estimation theory and extends the applications of the LCT in signal processing.

Keywords： High-speed PCB; Board-level EMC; Three-line Coupling Model; Via Holes

Abstract: Aim at the multi-faceted nature and universality of the EMC problems in high-speed PCB, based on a three-line coupling model and considering the influence of via holes caused, board-level EMC problems of PCB were researched on point for point. In this paper, the research and simulation were launched by a kind of software named Hyperlynx, and a 6-layer PCB model was built and used. Our Research was focused on the EMC problems existed in hierarchy and layer medium. On the basis of the simulation results, and combined with previous experience in the PCB design, some effective measures for improving EMC in high-speed PCB design were summarized, which could be taken as a clearly reference in design of high-speed PCB.

0. Introduction

High-Speed PCB (High - Speed Printed Circuit Board) usually refers to these Printed Circuit Boards of which the clock frequency more than 50 MHZ. The so-called EMC (Electromagnetic Compatibility), refers to the equipment or system can work properly in the electromagnetic environment, and the ability that doesn't cause the unsustainable electromagnetic disturbance to anything in the environment.[1]The design and using process in High-speed PCB will inevitably meet EMC problems, especially along with the rapid development of electronic products, previous design experience was often difficult to cope with the changing of the EMC requirements.[2] Therefore, this paper uses the simulation software named Hyperlynx for EMC research in the high-speed PCB, concluded scientific and effective improved design techniques and measures for board-level EMC.

1. Building of board-level EMC model

In high speed PCB layout, factors directly related to board level EMC involves dielectric thickness between boards, distance and isolation performance of signal layers, VCC layer's influence on signal layer, via hole, etc. The theoretical basis for simulation and analysis of board level EMC: [3]

$$i=\mathbf{C}\frac{\mathbf{du}}{\mathbf{dt}} \quad (1)$$

$$u=\mathbf{L}\frac{\mathbf{di}}{\mathbf{dt}} \quad (2)$$

Therefore, this paper study board level EMI degree by observing the simulation result of far end and near end voltage signal. The via hole's EMC analysis study the discrepancy in electromagnetic interference from different aperture D and depth H, and its theoretical basis is: [4]

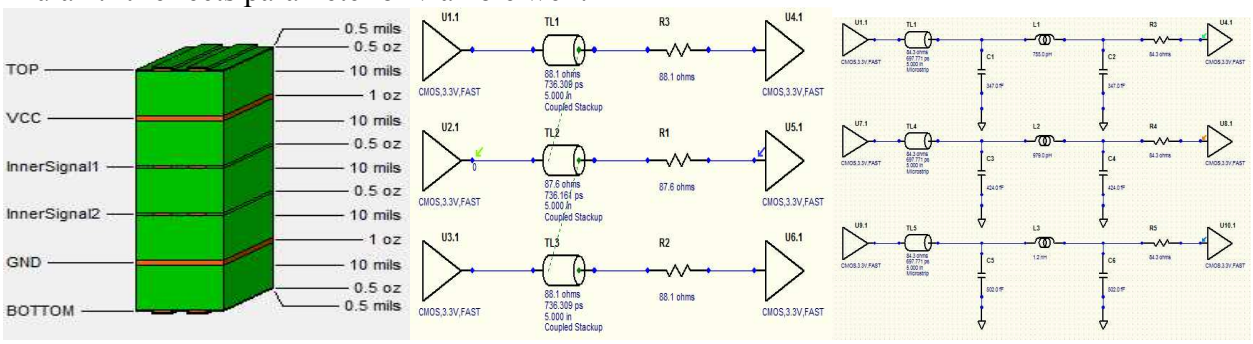
$$C=\frac{1.41\varepsilon TD1}{(DZ-D1)} \quad (3)$$

$$L=5.08h[ln(4h/d)+1] \quad (4)$$

In the type: C is parasitic capacitance to GND; ε is relative dielectric constant of PCB;D1 is pad diameter surrounding via hole; D2 is mesopore diameter in GND layer; T is thickness of PCB board; L is inductance of via hole; d is diameter of via hole; h is length of via hole.

Board level EMC model is showed in Figure1(a).PCB board has 6 layers which VCC layer and GND layer are placed at each side of signal layers to study the VCC layer 's interference degree in

signal layers. The reason for making two signal layers adjoining is that compare the difference of interference in adjoining layers and separated layers. Wiring in layer is coupled three-line model, showed in Figure1 (b).Two sides [5] are offensive wire and victim wire is in the middle. This model simulates the electromagnetic interference in board more veritably [6], showing great research value. Equivalent circuit of via hole is showed in Figure1(c)[7], which is according with Formula 3 and Formula 4. It reflects parameter of via hole well.



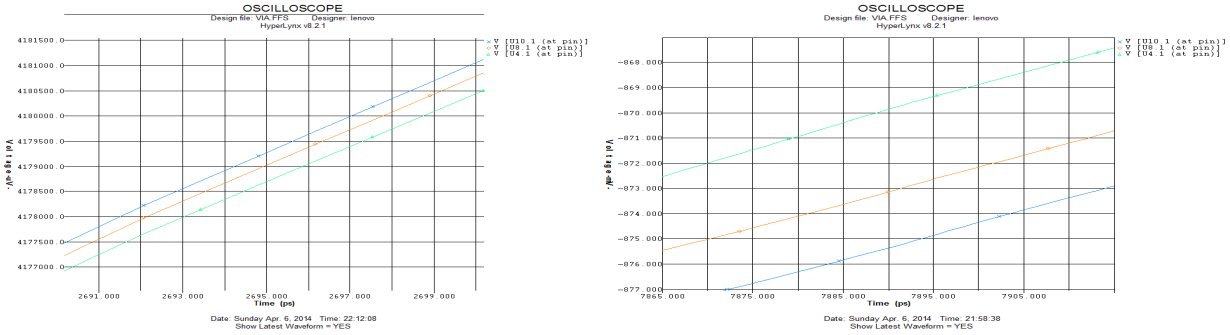
(a)Layer structure model (b) Coupled three-line model (c) Via simulation model

Fig.1. The simulated models

2. Simulation and analysis of board level EMC

This paper uses Hyperlynx8.2.1 to simulate and analyze board level EMC. Hyperlynx, developed by Mentor Graphics, is a kind of high-speed PCB simulation software. It can design and simulate EMC and SI of PCB board at different frequency. By means of changing parameters to simulate the above three models, the analysis of board level EMC has been achieved.

Via is PTH (Plating Through Hole) or named via hole. In high speed multilayer PCB, via is used to connect printed conductors in different layer or fix components. There are three types of via generally: buried via, through via and blind via. Through via is in common use because of its simple processing. This paper mainly analyze the through via diameter d and through via depth h to study via EMC.



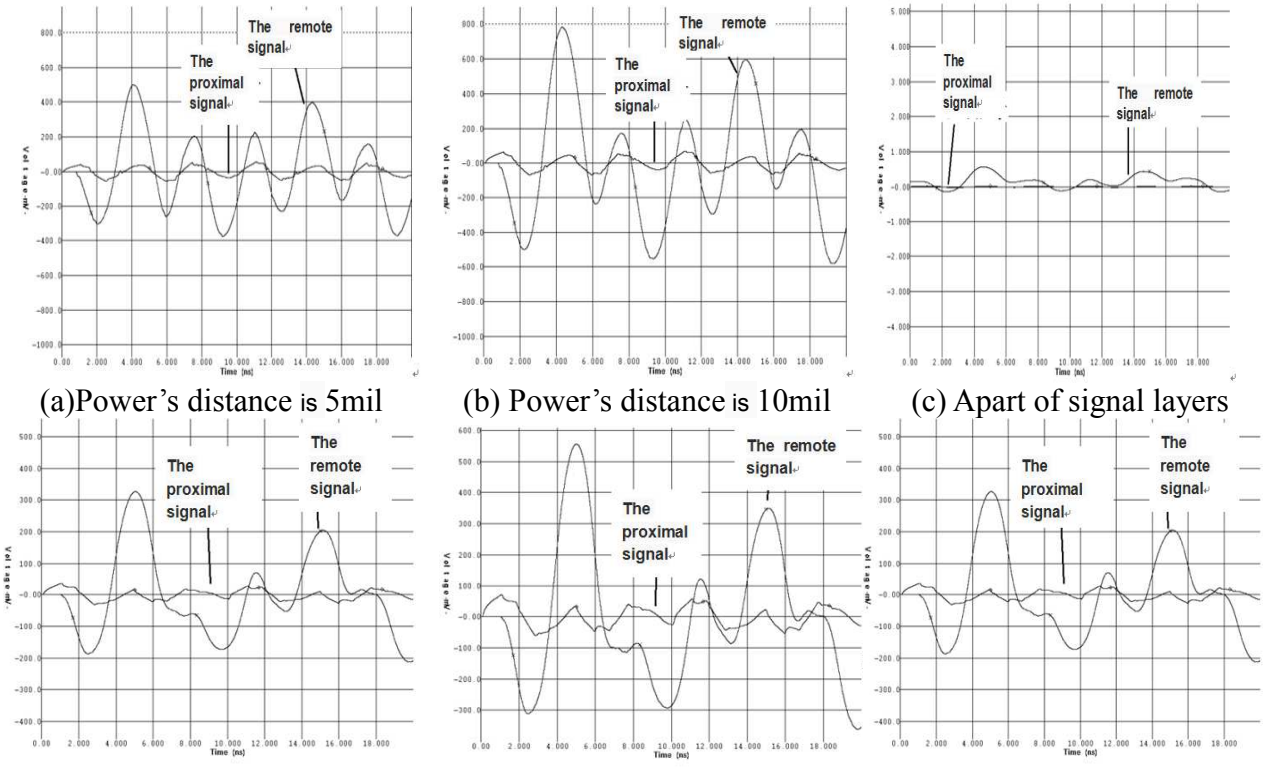
(a)Different via diameters (b) Different via depths

Fig.2. The results of vias' EMC simulation

Figure2 (a) shows electromagnetic disturbances with different via diameters, which are 10mil, 15mil and 20mil from top to bottom. Thus, the smaller diameter it is, the greater disturbance.

Figure2 (b) shows there are diverse disturbances with different via depths. The depths are 65mil, 55mil and 45mil from top to bottom. By comparison, the hole is longer, the disturbance of signal is greater.

Lamellar layer model analysis is based on three-line coupling model, to compare electromagnetic interference among different layers. Mainly for the thickness of the dielectric between the plates of electromagnetic interference, differences electromagnetic interference caused by signals of different spacing of adjacent layers, differences between adjacent signal layers and separated layers, and effects of the power supply layer and the signal spacing layer.



(a)Power's distance is 5mil (b) Power's distance is 10mil (c) Apart of signal layers

(d) Adjacent signal layers (e) Layers' interval is 5mil (f) Layers' interval is 10mil

Fig.3. The results of layers' EMC simulation

This article assumes that the power level of the signal layer significantly interfere with signal transmission, therefore, to observe its effects by adjusting the layer spacing. The simulation results are shown in Figure3 (a), Figure3 (b). Comparison shows that there is little difference between near-end signals although the distance between the plates is not the same. We can see that signal interference is slightly larger when they apart from 10mil.Remote signal interference significantly different. When the power supply layer and the signal layer separate from 5mil, remote disturbance signal's maximum value of peak to peak is V5p-p=812.61mv, but when the power supply layer and the signal layer separate from 10mil, remote disturbance signal's maximum value of peak to peak is V10p-p=1270.60mv. It can be seen that the closer signal layers to the power supply layer, the smaller electromagnetic interference.

Assuming adjacent signal layers are InnerSignal1 and InnerSignal2, separated layers are Top and InnerSignal1.From Figure3 (c) and Figure3 (d) we can see, when the signal layers separated, there is almost no near-end signal disturbance, the maximum value of peak to peak of remote disturbance signals is less than 1mv. When comes to adjacent signal layers, the maximum value of peak to peak of near-end signals is Vnearp-p=55.24mv, the maximum value of peak to peak of remote disturbance signals is Vremotep-p=513.69mv. We can conclude that adjacent signal layers' interference is larger when signals transmitted simultaneously, so signal layer should be clothed in a position apart when clothing boards.

This paper makes the spacing reference value between adjacent signal layers 10mil, using the spacing of 20mil signal disturbance simulation to contrast with it. From Figure3 (e) and Figure3 (f).we can see that when the distance of adjacent signal layers is 10mil, the maximum value of peak to peak of near-end signals is V10p-p=124.08mv, the maximum value of peak to peak of remote disturbance signals is V20p-p=862.60mv. When the distance of adjacent signal layers is 10mil, the maximum value of peak to peak of near-end signals is V10p-p' =60.49mv, the maximum value of peak to peak of remote disturbance signals is V20p-p'=508.74mv. We can conclude that the smaller the spacing between adjacent signal layers, the greater the intensity of the signal interference between each other.

3. EMC improved measures in high-speed PCB

According to the above results, together with previous experience in high-speed PCB design and material, conclusions can be drawn as follows:

(1). Minimize non-essential vias when designing PCB

(2). Appropriate to increase the power and ground connection vias to minimize impedance, and minimize the diameter of the vias if lower cost and crafts are allowed.

(3). Reduce the length of the vias In the design of the acceptable range, maximize the use of micro-holes and Back-Drilling Technology[8], and try to weaken the implications of the hole on the EMC

(4). Possible to reduce the thickness between the signal layer and power layer, a ground layer of the dielectric layer when doing stack design, in order to reduce the magnitude of crosstalk noise[9]

(5). Try to avoid signal layer adjacent when designing the hierarchy of PCB, if it cannot be avoided, we should also increase the distance between two adjacent signal layers to reduce signal interference between each other.

4. Conclusion

In view of a series of EMC problems in the design, testing, using process of high-speed PCB, on the basis of the relevant theoretical research, the lamellar model, the three-wire coupling model and the vias model were built and simulated by Hyperlynx in this paper, coherent analysis of the factors which mainly affect board-level EMC was made, to give the corresponding effective measures to improve board-level EMC of PCB. The results provided effective guidance on Multilayer design, wiring and layout design and anti-interference research.

Keywords: texel; pixel; texture mapping; Creator.

Abstract: In the visualized simulation, the application of texture mapping technology can significantly improve image fidelity and superimpose the rich texture details to the surface, making the scene more realistic with real-time and fast invocation. This paper introduced the principle of texture mapping, the mapping process and implementation in software, and described in detail the implementation process of multi-layered texture mapping by example.

Introduction

There are usually surface details or texture on the surfaces of three-dimensional objects in the real world. The texture can be divided into color texture and geometric texture. Wherein, color texture can show the surface details through the changes of color or brightness while geometric texture refers to the microscopic geometry of the object surface. However, this will add to the amount of calculation of the imaging system. Therefore, texture mapping technology is usually applied to achieve this goal. Texture mapping technology is of the fastest growing 3d technology in recent years, it has become the most recognized can measure 3d image quality technical standards, all graphics standard provides support for texture mapping[1-4].

Texture mapping principle

The nature of texture mapping is to deal with 3D objects by two-dimensional parameters, which is to determine two-dimensional parameter values of any point on the surface of a three-dimensional object, then get the texture value at that point, and finally create the texture image of the 3D image surface. Texture mapping is mainly to identify the mapping relationship and deal with the anti-aliasing of texture so that the highly realistic effect of image can be realized with less time and space. The core problem during adding texture pattern to the smooth surface is mapping, therefore, texture mapping can be simplified as the transformation from one coordinate system to another one. Wherein, there are at least two mapping: first, mapping from texture space to scene space, sometimes called curved surface parameterization; second, mapping from scene space to image (screen) space, namely the viewing transformation. These two kinds of transformation are usually integrated as one.

If the texture pattern is defined within an orthogonal coordinate system (u, v) in the texture space, and the curved space is defined within the orthogonal coordinate system (x, y, z) in the scene space, which is represented as x (θ, φ), y (θ, φ), z (θ, φ) in the parameter space (θ, φ). Then, the addition of texture to the curved surface will relate to the determination of a mapping function between two curved surfaces. For example, the mapping from the texture space to parameter space is:

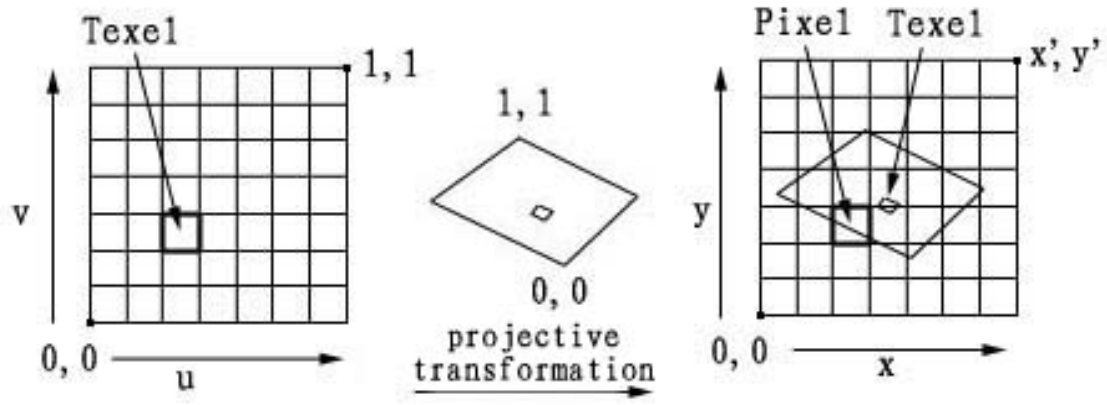
$$\theta = f(u, v), \varphi = g(u, v) \tag{1}$$

and the reverse mapping from the parameter space to texture space is:

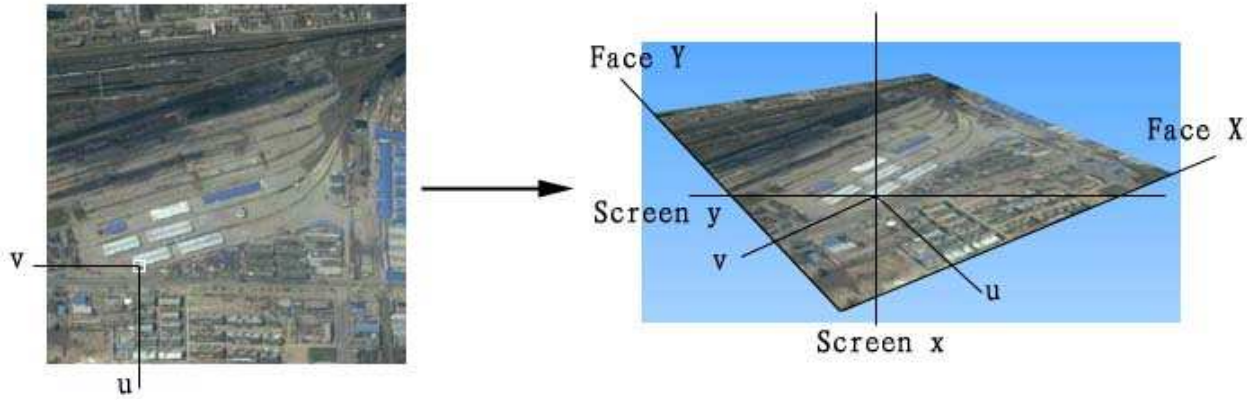
$$u = r(\theta, \varphi), v = s(\theta, \varphi) \tag{2}$$

The texture space is a coordinate space that takes u, v as the horizontal and vertical axis respectively. In the coordinate space, the coordinate values of the upper-right corner of the texture image are (0, 0) and (1, 1) respectively. The minimum unit of the texture image in texture space is texel as shown in Fig. 1 (a). And the smallest unit in the terminal display screen coordinate space is pixel as shown in Fig. 1 (b). The two-dimensional texture image will finally be mapped to the

three-dimensional surface model and the actual size of the texel is determined by the resolution and scaling of the texture mapping process in the two-dimensional texture image as shown in Fig 1 (c).



(a) The texture space coordinates (b) Screen space coordinate system



(c) The texel displayed on the screen space coordinate system

Fig.1 Schematic Texture Mapping

As the viewpoint in the simulation process will be changing, the size of model object after mapping to the screen space will also be changing. There will be three different scenes of the texture mapped on the model object surface in the actual process of rendering: first, one texture image texel properly corresponds to one pixel on the screen which is an ideal situation that the texture image is a full-size mapping; second, multi-texture image texels are mapped to a same screen pixel; third, one texture image texel is mapped to several screen pixels. For the second situation, the minification filter is conducted to the texture image. For the third situation, the magnification filter is needed to deal with the texture image. When the viewpoint position changes, through corresponding filter, the texture images can be softened, sharpened or fused so as to obtain better rendering effects.

Texture mapping Process and Implementation

Texture Mapping Process. Texture images that are read are generally two-dimensional. The texture coordinates are used to define the mapping from image to geometry. The u, v coordinates of the texture are mapped to screen space coordinates and the colors of texture, the polygon and the material are fused. Then the appropriate texture processing, such as the nearest neighborhood filtering, bilinear interpolation and Mipmap is carried out. The nearest neighborhood filtering is to choose the nearest texel for each pixel while the bilinear interpolation is to interpolate with the nearest four texels for anti-aliasing and optimization effect which is better than the method of nearest neighborhood filtering. The optimal treatment is Mipmap, which can pre-process the texture and construct the data structure of fast approaching calculation for multi-texel covering single pixel.

From the Angle of storage structure of the texture, texture is actually a storage array of two-dimensional image color information, and grain element is composed of color channel. Store one

color channel need eight bits, which is a size bytes . According to different color channel number and the way of compression, the texture image can be stored for a variety of formats, Creator can support a variety of universal standard image formats, main formats including: contains only one gray channel INT, contains a grayscale channels and a transparency of INTA, including red, green and blue three color RGB channels; Include red, green and blue three color channels and a transparency RGBA; As well as TGA, JPEG, TIF, GIF, BMP format. In addition, the Creator also supports CT (clip texture) and other advanced special format textures. Some format of the texture while in the Creator can normal use, but can not be displayed correctly in the real-time system.

Before the real-time system should map the texture used by the model database, the corresponding texture image should be uploaded in the texture memory in advance.

The necessary texture memory = the texel size in X direction × the texel size in Y direction × the number of color channels

Texture memory is designed for loading and storing texture image memory space, most of the real-time system has a dedicated texture memory, and some real-time system directly to the texture image loaded into the system memory. In order to more effectively utilize the texture memory and the system can ensure real-time texture mapping is done correctly, the two directions in the texture image size must be a power of two sizes, such as 16 × 16,8 × 32,64 × 16,128 × 256, etc., the length and width may not be the same. If the texture does not meet this requirement using the image, then before mapping textures, real-time system will automatically adjust the texture image to the nearest power of a larger two forms, although this does not affect the final texture mapping results, but will reduce the efficiency of the texture memory.

The memory capacity of the real-time system texture is limited, so the size of the texture image used in the process of creating model database must be moderate. If the size is too small, the visual effect may be influenced and if it is too big, the texture memory space will be wasted.

The Realization of Texture Mapping in Software. Creator is a professional 3D modeling software developed by Multigen-Paradigm. It can be used to complete the three-dimensional model simulation system[5]. First, Creator is run, then the needed texture images are transferred to the texture palette and the current texture is specified. Then, the target surface is chosen and the current texture is mapped to the polygon with the texture mapping tool in the texture toolbox or the setting texture tool in the property toolbox. Creator can also provide texture mapping palette to store and reuse the texture mapping information. After the texture image fodders are uploaded into the texture palette in the model database, the above tools can be used to map the texture images to the surface of the polygon and preview the real-time texture mapping effects.

Must first be transferred to the desired texture image texture palette, specify the current texture, and then select the target surface, using texture mapping tool in the toolbox or properties set the texture tool in the toolbox to the current texture mapped onto polygons. After the image is loaded into the model texture palette, users can use a texture toolbox or properties of various tools in the toolbox, the texture image is mapped onto the polygonal surface model of the object. Enabling view panel displays in texture button, you can preview the effect of texture mapping model objects in a graphical view. For a model of texture images containing transparent channel must be enabled in order to view panel transparency blending function correctly displayed in the graphical view of the transparent texture mapping.

The texture mapping of Creator can be divided into the following categories: Put Texture can determine texture mapping by setting the selected three points on the plane and can modify the number of affixed textures to change the elaboration and change the shape of the textures to realize special effects; 4 Point Put Texture can determine the basic differences between texture mapping, function and three-point plane mapping; Surface Project Texture conducts texture mapping to the selected object or plane according to plane and the elaboration of the texture can be adjusted directly; Spherical Project Texture conducts texture mapping from the symmetrical center of the object top and bottom surfaces; Radial Project Texture conducts texture mapping radially from the object top surface center; Geo-Put Texture changes texture shapes according to the ground surface situation so as to

perfectly integrate the texture and ground; Environment Map Texture shows the scenes around the object by a pattern and maps to the curved surface that encloses the object, without affixing patterns or specular reflective texture. The texture changes as the direction and perspective of the object change. Different methods of texture mapping correspond to different geometrical models and the specific situations should be determined by the specific shapes of the models.

In Creator, in addition to these above single texture mapping methods, multi-level texture mapping may also be used to represent the complex local details of the model object without adding any extra polygon. Multi-level texture mapping is highly efficient with high distinction. With examples below, we will describe its realization. To simulate the mottled marks on the walls and vegetation, we only need to map three levels of different textures on the wall polygon and then we can realize the necessary effects as shown by Fig 2. In Creator, these three different levels of textures are read into the texture panel. In the view panel, we select the texture layer of Layer0, Layer1, Layer2 and the wall geometrical polygon surface. Then Put Texture is applied for texture mapping. Layer0 adopts the wall brick pattern (Fig. 2(a)); Layer1 uses the mottled marks texture (Fig. 2(b)), and Layer2 adopts vegetation texture (Fig. 2(c)). The Texture option in the view panel is modified to Blend so that the wall simulation effects of three-level texture mapping can be observed in real time (Fig. 2(d)).

(a)wall brick texture (b) mottled marks texture (c) vegetation texture (d) three-level texture mapping simulation wall

Fig. 2 Multi-level texture mapping

Conclusions

The texture mapping technology is an important part of photorealistic, and its application can guarantee the representing of rich details of three-dimensional objects with fewer polygons, which both meets the real-time need and better realizes the sense of object reality. In practical application, the multi-level texture mapping can better show the advantages of model surface details description. The technology will definitely be widely applied to the visualized simulation system.

The Discussion on The Improved Association Rules Algorithm in Data Mining

Wen Tao, Sun Li, Zhu Li
Jiangxi Science & Technology Normal University Nanchang, China
191200933@qq.com

Keywords: association rules; data mining; algorithm improvement

Abstract: The data mining can help to extract the information and knowledge with potential application value from a huge amount of data. In order to do the date mining scientifically and efficiently, this article provides an improved algorithm based on the classical association rules Aprior algorithm, taking advantage of which, we can engage in the association rules mining of the database to obtain the useful information. The improved algorithm avoids pattern matching and reduces the number of times of visiting the database, thus improves the speed of date mining to some extend.

Ⅰ. INTRODUCTION

The data mining is based on the knowledge finding in the database. This is the process of exacting the potentially useful information from the database and by digging out the underlying information, offering the knowledge and rules with value to the decision maker. The association rule is like the rule below:" Among the young customers who bought the beer and cigarette, there are 60% buying the baby diapers" (beer+butter+baby diapers). The main object of association rule mining is the transactional database. In the aspect of sales data application, a transaction usually includes the customer id NO., the purchase items, the time spend, etc.

Ⅱ. THE METHOD OF ASSOCIATION RULES MINING

A. The general steps of association rules mining

Find out the preliminary data related to the task. Deal with the specific problem properly and form the normalized database. Generate the frequent item set. Retrieve the frequent item set from the normalized database, namely the rules with the support no less than the minimum support set by the user. Output the visualization rules. Find out the rules that meet the requirement of the minimum support set by the user from the frequent item set and then conduct the visualized output of the rule set.

B. The description of the association rules.

Definition 1. If the item set Y has the number of m items, we call the length or the size of Y m. Then the item set Y can be described as m item set.

Definition 2. If the support of the item set Y is more than the minimum support, then we call the item set $Y \in I$ the frequent item set.

Ⅲ. THE PROBLEMS IN APRIORI ALGORITHM

A. Apriori algorithm

The frequent item set method of the Apriori algorithm has become the efficient tool to dig out the association rules in large database. By the way of iterative method, this algorithm generates the smaller frequent item set L[m] which then generates the bigger candidate frequent set C[m+1]. Then by searching the transactional database, the algorithm determines which candidate item set is frequent or not. This cyclic process continues until it can not generate the candidate set.

Algorithm: Apriori

Input (1). The format of the transactional database D is (TID,Item_set), TID is the transaction identifier, Item_set is the item set corresponding to the transaction. (2) The user's minimum support: min_sup.

Output: the whole frequent item set

```
begin
  L1={frequent 1-item_set}
    for(i=2;Li-1<>Φ;i+ +){
        Ci=apriori_gen(Li-1)
        for all transaction j∈D do{
          Cj=subset(Ci,t)
            for all Candidate   c∈Ci do   c.count++}
        Li-1={c∈Ci   c.count>=min_sup}
}
    answer=YiLi-1
end.
```

Apriori_gen is the function generated from the candidate item set with the frequent item set as the independent variable. This function returns the superset of all frequent item set m.

TID	Item_set
11	ACD
12	BCD
12	ABCD
14	BE

Fig.1 The transactional database D

B. The defects of the Apriori algorithm

Large redundancy. For example, assume the association rule that "cake" can derive ("milk","fruit") [confidence=76%]. It means 76% of the people who buy the cake will buy milk and fruit. However according to the Apriori algorithm, it will generate several association rules below:"cake" derives "milk" [confidence=83%]. It means 83% of the people who buy the cake will buy milk. "Cake" derives "fruit" [confidence=87%]. It means 87%of the people who buy the cake will buy fruit. {"Cake", "milk"} derives "fruit" [confidence=80%]. It means 80% of the people who buy the cake and milk at the same time will buy fruit. {"Cake", "fruit"} derives "milk" [confidence=89%]. It means 89% of the people who buy the cake and fruit at the same time will buy milk. There are some differences in the meaning in these association rules. However the association rule that "cake" derives {"milk" "fruit"} actually includes the four rules above, which means in another way that the association rule of "cake" deriving {"milk", "fruit"} can automatically derive the four association rules above.

It is easy to generate worthless rules or even the incorrect results. Take the 5000 high school students' activities of doing morning exercise for example. The investigation shows that 1500 students attend the activity of "playing basketball", 4500 students attend the activity of "running", and 1000 students attend the activity of both "playing basketball" and "running". If we assume that min_sup=15%，min_conf=60%, according to the Apriori algorithm, we can get the association rule: "playing basketball" derives "running" [support=15%，confidence=75%].

It means that if there are 75% of the students attending the activity of "playing basketball", they will attend the activity of "running" too. It is totally reasonable to reach this conclusion from the

derivation, but this rule is actually misunderstanding for the reason that the proportion of the students who attend the activity of “running” in the total students is as high as 90%, which means it is sure that 90% of the students will attend the activity of “running”. However the proportion of 90% outstrips the minimum confidence of 60% and also exceeds the rule confidence of 75%. Thus the information conveyed by the rule is worthless.

Ⅳ. THE IMPROVED ASSOCIATION RULE MINING ALGORITHM

A. The thinking for the improvement.

In the view of the above problems, we improve the algorithm accordingly. On one hand, we adjust the data structure. Namely we change the currently common used flat data structure into the data structure where the item vertically corresponds to the transaction. This vertical data structure is composed of the item set and the transaction table which contain the set of item. Change the picture 1 the transaction database D into the picture 2 blow.

C
11
12
13

D
11

E
12
13
14

Fig.2 The expression of the database with the item vertically corresponding to the transaction

Definition 3: Given the item set Y and the transaction database D, the vertical database D’ is {X，M}, and X ∈Y, M={TID1,TID2,…,TIDn}. The transaction TID in D is TIDi(i=1,2,…,n), which contains the item set Y.

This structure solves the problems caused by the flat data structure. The reasons are following: Obtain the frequent item set through database searching. When we identify the candidate item set AB which is consisted of the item set A and item set B whether is the frequent item set or not, we can get the support of the item set AB by calculating the number of the same transactions in the transaction set of item A and item B, which can avoid the pattern matching. Visit the database only once. It is only at the beginning it requires to visit the whole database. When m>1, if we calculate the support of the candidate item set in Cm, it only requires to visit the frequent item set Lm-1 . And with the increasing of m, the frequent item set gradually decreases. In this way the amount of the data that the algorithm needs to visit will shrink.

B. The improved algorithm.

Algorithm: Apriori_new

Input: the format of the transactional database D is (TID, Item_set). TID is the transaction identifier; Item_set is the item set of the transaction; min_sup is the user’s minimum support.

Output: the whole frequent item set.

```
begin
    f_genf1(min_sup)
    m=1
    do
        m++
        f_genf(m-1,min_sup)
        move record from D' where item_num=m-1
    loop while |Lm| >1
end
```

F_genf1 is the function used to generate a frequent item set. Firstly the function converts the transactional database D into the database with item corresponding to the transaction. Then query the converted database in order to get the support of all the items. Add the items that meet the criteria into the frequent item set and delete all the information of the item that do not meet the criteria from the converted database.

By the way of giving the same segment number to the frequent item set with the same prefix, we can get a certain frequent item set. Select the frequent item set and pick up items with the same segment number to form the candidate set and in this way, it can speed up the generation of the candidate set. Initially set the segment number of the frequent item set as 0, which means any two items can form a candidate item set with the length of 2. As for the item set with the same segment number, select the most front items to form a set firstly. Then set segment number of the candidate item set which is formed by the set mentioned before same. When the former item of the candidate item set changes, the segment number adds one. At the time of realizing this algorithm, calculate the frequency of the candidate item set as soon as it is generated. In this way, it can reduce the memory usage and increase the efficiency of the Algorithm.

Ⅴ. CONCLUSION

Based on the deep research of the characteristic of the association rules, this article finds that the association rules have the defects of large redundancy and tend to generate the rules in which the user is not interesting. In the light of the existing problems of the Apriori Algorithm, this article puts forward with the Aprior_new Algorithm. In the process of examining the database, we assume that every transaction contains four items and every item has 50 initial numbers. The tuple number of transaction in database examining starts from 400 and then taking the amplification method successively increases to 1500. The minimum support is set to 4% and the confidence is set to 55%. It is proved that the Apriori_new Algorithm is much more efficient than Apriori Algorithm. Apriori_new Algorithm also is tested in the environment of windows by the means of Delphi 2010. The run results prove that the improved Apriori_new Algorithm is correct and efficient.

An information classification optimization model based on improved ant colony algorithm

HAO Chun-mei[1]

[1]Department of Computer Science, Harbin Finance University, Harbin Heilongjiang 150030, China

[a]may_hao@126.com

Keywords: improved ant colony algorithm ; data management ; Information Classification

Abstract. In the information management process, it is necessary to classify all information optimization to provide the support for quickly query the search target providing this, a classification optimization method based on improved ant colony algorithm is proposed in this paper. That is, extract the characteristics of information attribute, and then establish the optimization classification model based on the characteristics to achieve the classification of information. Experimental results show that using the improved algorithm for classification information, the classification accuracy can be improved to meet the actual demand data management.

Introduction

With the continuous development and popularization of computer vision technology, computer data management technology has been gradually applied to different areas, played a huge role[1]. Faced with a flood of information, how to select the information that users need has become the focus of information management issues that need to be studied[2]. Thus, the method to classify a massive information become an important subject in computer field[3].At this stage, the main methods for massive information include the massive information classification method based on K-means clustering and the massive information classification method based on Gaussian model. Among them, the most commonly used method is the massive information classification method based on Gaussian model. Considering the fact that the methods for massive information classification have a vast space of development, therefore, it attracts attention of many experts and has a board development potential.

Related principles of Information classification optimization methods

A. Extract attributes characteristics of information

Let $a=(a_1,a_2,\cdots,a_r)^T$ be the set that contains all the attribute characteristics, $U_a=H[aa^T]$ be the matrix that stands for all the information attribute characteristics, the set contains the difference of above information attribute characteristics is $F_a=H[(a-\overline{a})(a-\overline{a})^T]$. Using the following formula to calculate all information attribute characteristics:

$$b=X^Ta=(x_1,x_2,\cdots,x_r)^Ta=\begin{bmatrix}x_1^T\\x_2^T\\\vdots\\x_q^T\end{bmatrix}a \tag{1}$$

In above formula the value of $b_l=x_l^Ta$, $l=1,2,\cdots,r$, a can be calculated by following formula:

$$a=(X^T)^{-1}b=X_bb=X^Ta=(X^T)^{-1}b=X_b$$

When extracting the attribute characteristics of information, it is necessary to use following formula to calculate the weight:

$$\hat{b} = \sum_{m=1}^{r} cy_m + \sum_{m=r+1}^{s} fy_m \tag{2}$$

The extraction of information can be done by following formula:

$$M = \sum_{l=q+1}^{r} [x_l^T F_a x_l - w_l (x_l^T x_l - 1)] \tag{3}$$

In above formula, w_l stands for the matrix of all information attribute characteristics, x_l stands for eigenvectors of the corresponding information.

The procedure of the improved ant colony algorithm is:

nc←0；

According to the heuristic factor $P_i(t)$, update factor τ_{ij} ,step factor $\Delta\tau_{ij}$ and start the initialized process;

Put the initial position of m ants respectively at the ninformation classification targets.

Record the initial position of the m ants and add into the set of initial positions;

Using the improved ant colony algorithm to transfer the k-th ant based on the transition probability.

After the initial search, record thecrawling length L_k of each ant.

Record the optimal solution among the all the ants.

According to the heuristic factorupdate formula update the heuristic factor.

nc←nc+1;

If nc< λ (scheduled times) then go to step 2);

Out put the final results.

Thus, the ant colony searchbased on the personalized service items can finally complete the establishment of classification optimization model, which improved theaccuracy and effectivenessof information classification.

Simulation and Analysis

In order to verify the effectiveness of the proposedinformation classification method based onimproved ant colony algorithm, it is needed to perform aexperiment.In the experiment, MATLAB can be used to build to simulation environment.

Respectively use the traditional algorithm and the proposed algorithmto performinformation classification optimization process, the obtained results can be shown as following two graphs.

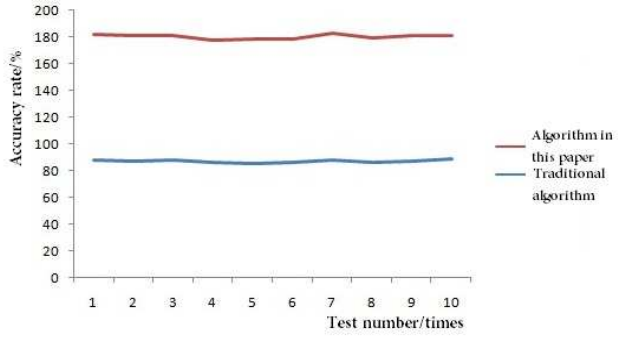

Figure 1. Comparison of accuracy of different algorithms

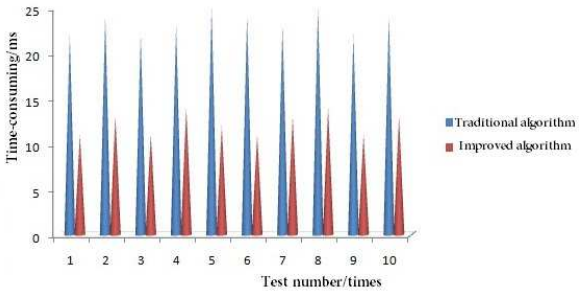

Figure 2. Comparison of time consumption of different algorithms

Summarize the above experimental data, table 1 and table 2 is shown below:

Table 1. The experimental data of traditional algorithm

Times	Accuracy (%)	Time(ms)
1	88	22
2	87	24
3	88	22
4	86	23
5	85	25
6	86	24
7	88	23
8	86	25
9	87	22
10	89	24

Table 2. The experimental data of proposed algorithmby this paper

Times	Accuracy(%)	Time (ms)
1	94	11
2	94	13
3	93	11
4	92	14
5	94	12
6	93	11
7	95	13
8	94	14
9	94	11
10	92	13

Using the proposed algorithm to performinformation classification experiment, the accuracy of classification is higher then the traditional algorithm, besides, the time consumption is also shorter, the advantage of the proposed algorithm can befully demonstrated.

Conclusions

This paper presents a method based on improved ant colony optimization algorithm information classification. Extract the characteristics of information attribute, and then establish the optimization classification model based on the characteristics to achieve the classification of information. Experimental results show that by using the improved algorithm for classification of information accuracy of the classification can be improved,the time consumed on classification can be shorten which means the improvement of efficiency in information classification.Hence, the resultis satisfied.

Simulation analysis of a statistical model for herd mentality trend

Pan Shiying

Sichuan college of architectural technology,sichuan,618000

Keywords: herd behavior; herd mentality; herd consumption

Abstract: Herd mentality is a universal, objective social psychological phenomenon in humans describing how people are influenced by their peers to adopt certain behaviors even against their wishes. Herd mentality has a dual nature. This paper analyzes the performance and causes of herd mentality, and makes appropriate adjustment strategy, which has great significance to both the individual and national development.

1 Introduction

Herd mentality is a universal, objective social psychological phenomenon in humans describing how people are influenced by their peers to adopt certain behaviors even against their wishes [1]. Herd mentality has a dual nature, positive factor and negative factor. The positive factor is that it makes individual cognition and behavior complying with community, social norms, is conducive to increase the activities and objectives of efficiency, helps to learn the wisdom of and experience of others, expands horizons, and overcomes opinionated and modify the way of people's thinking. On the other hand, it also has negative factor which refers to inhibit the development of personality, structure thinking, and make people non-assertive and blindly [2]. Herding is a tendency people consciously or unconsciously make their behavior and reactions consistent with others, in objective or psychologically ambiguous situations [3]. Individuals in the population are often unwittingly subjected to groups' pressure, and tend to has same behavior, perception, judgment, and beliefs with most people in the population [4].

With the rapid development of media technology, media, social environment have a broad and profound impact on public ideology, ways of thinking, values, behavior, etc., and also the performance characteristics of public's herd mentality [5]. Under the new historical conditions, studying the phenomenon and characteristics of herd mentality and actively guiding the public have guiding significance for doing social work [6]. Based on previous studies, combined with the characteristics of today's society, the paper presents a comprehensive in-depth analysis of the causes and performance of herd mentality, and gives some appropriate means of regulation.

2 Herd mentality statistical model

Getting some results related to the topic through network, learning some useful information, we use SPSS statistical software to conduct mathematical statistics, and finally get the required data in this article.

We uses Markov chain to describe the evolution of the herding. In order to more easily obtain a balanced distribution, we use a reversible Markov chain with one-step transition probabilities as

$$P_{k,\,k+1}=\frac{N-k}{N}\bullet\left[\varepsilon+\delta\bullet P\left\{\eta\ \rangle\frac{M}{2}\right\}\right] \quad (1)$$

$$P_{k,\,k+1}=\frac{k}{N}\bullet\left[\varepsilon+\delta\bullet P\left\{\xi\ \rangle\frac{M}{2}\right\}\right] \quad (2)$$

$$P_{kk}=1-P_{k,\,k+1}-P_{k,\,k-1} \quad (3)$$

As shown in formula (1) and (2), we add a small probability ε on the herd transition probabilities $\delta\cdot P\{\eta>\frac{M}{2}\}$ and $\delta\cdot P\{\xi>\frac{M}{2}\}$ of two types of people to avoid k=0 and k=N being absorbing wall of Markov chain.

Balanced distribution of the Markov chain is

$$\pi_k = \begin{cases} \pi_0 P_{00} + \pi 1 P_{10} & k = 0 \\ \pi_k P_{kk} + \pi_{k-1} P_{k-1,\ k} + \pi_{k+1} P_{k+1,\ k} & k = 1,\ \ldots,\ N-1 \\ \pi_N P_{NN} + \pi_{N-1} P_{N-1,\ N} & k = N \end{cases} \quad (4)$$

According to Kolmogorov reversible criteria, this Morkov chain is reversible that means a balanced distribution satisfies

$$\pi_i P_{ij} = \pi_j P_{ji},\ \ j = i \pm 1 \quad (5)$$

So we have $\frac{\pi_k}{\pi_{k-1}} = \frac{P_{k-1,\ k}}{P_{k,\ k-1}}$ (6)

Mark $V_k \frac{\pi_k}{\pi_0} = \begin{cases} 1 \\ \prod_{i=1}^{k} \frac{\pi_i}{\pi_{i-1}} \end{cases}$ (7)

$$V_k \frac{\pi_k}{\pi_0} = \begin{cases} 1 & k = 0 \\ \prod_{i=1}^{k} \frac{\pi_i}{\pi_{i-1}} & k \neq 0 \end{cases} \quad (8)$$

We can get $\pi_k = \frac{\pi_k}{\pi_0 + \pi_1 + \ldots + \pi_N} = \frac{\frac{\pi_k}{\pi_0}}{1 + \frac{\pi_1}{\pi_0} + \ldots + \frac{\pi_N}{\pi_0}} = \frac{V_k}{V_0 + V_1 + \ldots + V_N}$ (9)

3. Simulation and Analysis

3.1 The simulation

Taking a secondary school for example, we distribute store posters at the school gate. There are many factors that affect the experimental results: store posters, product category, selling list. Then, observe and analyze changes of herd behavior trends of college students impacted by the sales volume charts.

According to the assumption, we choose supermarket as experimental place.

(1) Product Selection: some kinds of food and drinks

(2)The influence of the best selling products sorting on the real situation: slight change and before and after order is reversed.

Following are the detail information about the experiments.

Choose five kinds of products in the supermarket in male dormitory: Pepsi cola, sausages, instant noodles, peanuts, sliced bread, statistic each day's sales (of three days) and total rankings (the real ranking are Pepsi cola, sausages, instant noodles, peanuts, sliced bread)

According to the total sales of the three-day, we present Sales Rank on posters (make slight changes), and then statistic the Sales in the following three days.

3.2 Experiment results

Table 1 Effect of sales posters

Products	before distributing posters			after distributing posters		
	1st day	2nd day	3rd day	1st day	2nd day	3rd day
sliced bread	2	1	2	13	10	15
peanuts	2	3	2	8	13	10
instant noodles	5	6	6	15	14	22
sausages	1	1	0	7	5	8
Pepsi cola	3	3	2	15	13	18

Note: It can be seen that the Sale ranking has a certain effect on the purchase behaviors, but has difference in different products.

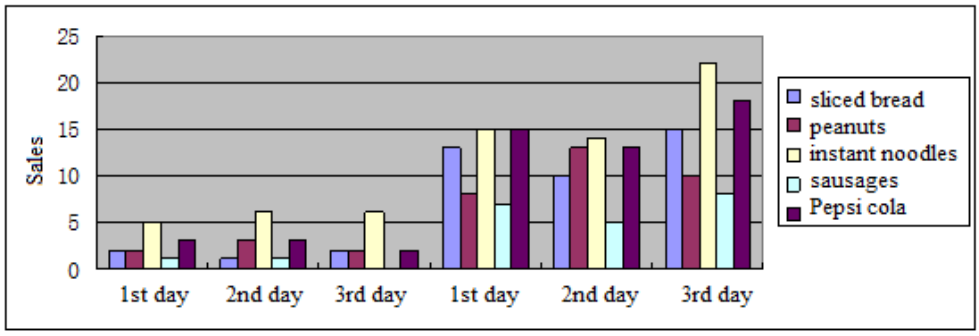

Figure 1 The change in sales before and after posters distributed

Description: From table 1 we can infer that: first, before distributed posters, sales of some products are not stable; second, after distributed posters, sales of most products have increased; third, sales of sausages and cola keep increasing, and sales of other products are fluctuate; fourth, sales of cola and sausages have the largest increase.

Exploratory factor analysis is needed to be carried out to the data, in order to purify the measurement project aims. Therefore, we must first examine the correlation, since higher correlation is more suitable for factor analysis. Use SPSS 17.0 to carry out KMO measure and Bartlett Sphere test for sample data to determine the relevance, the result are shown in Table 2.

Table 2 Results of KMO and Bartlett test

KMO and Bartlett test		
Sampling enough degrees of Kaiser - Meyer - Olkin measurements		0.646
Bartlett sphericity test	The approximate chi-square	0.646
	df	2007.533
	Sig	.000

As inferred from Table 2, the KMO value is 0.646 and the Bartlett value is notable on 0.000, which mean the date is suitable for factor analysis.

3.3 analyses

Studies have shown that when faced with uncertain choices, people are easier to conduct herd behavior to avoid wrong choice. General psychology of consumers might be: the goods most people chosen will not too bad, in another words, the probability of error is very low.

As the sales trend after posters, the sales of original first and second products have significant increases and continue maintaining the rank. Since the ranking is real, selling promotional information and is consistent with and reinforce routine information, thereby greatly enhancing the possibility of herd behavior. As Elliot Aronson mentioned in "social animals": the result of observe and comply with other people in order to obtain information on how to conduct properly will be more powerful than just to get away from punishment or reward to comply with others. Experimental results fit the theory.

4 Conclusions

Based on summing up the theory of social psychology and group behavior theory research results, this study presents a statistical model of herd mentality trend, and uses empirical research to validate the model. From simulation and analysis of a college, we can see that college students have significant herd behavior when shopping.

Herd mentality has a dual nature, positive factor and negative factor. It makes helps individual to learn the wisdom of and experience of others and expand horizons, but inhibits the development of personality, structure thinking, and make people non-assertive and blindly. Therefore,

understanding the impact of related factors of herd behavior has a strong practical significance on both individual and community.

Virtual simulation of aerobics movement based on vision

Wang Xiaohui

Henan Radio and Television University zhengzhou Henan 450000,China

Keywords: 3D motion reconstruction, neighborhood correction, Feature points

Abstract: In aerobics, the motion state randomness of key feature points is great, so it is difficult to establish an accurate dynamic model for sports' shape base. Traditional 3D reconstruction algorithms use fixes shape base which hardly expresses the change parameters of complex movement and motion law of large-scale dynamic features, thereby leading to non-realistic reconstruction results. The paper proposes a new reconstruction algorithm for aerobics 3D motion images that corrects the neighborhood system of feature points by motion parameters until the parameter is stable to ensure accuracy and the stability of correction. The simulation results show that, the proposed algorithm avoids drawbacks of sports reconstruction results caused by the great randomness of aerobics' motion state, thereby complete 3D reconstruction for aerobics' motion images.

1 Introduction

With the improvement of people's living standards, more and more people continue to pursue good health. As a modern fitness method, aerobics has accepted by many people. Aerobics is an emerging sport in our country. It is originated in life pursuing both health and beauty [1,2] and combining aerobic, dancing and music. Therefore, physical beauty evaluation method is essential for aerobics. [3]

Computer Vision Graphics method is a computer-aided tool rapidly developed along with modern computer technology, and is well applied to a variety of occasions. The method analyzes physical beauty of aerobics through the combination of computer vision and image processing is in the initial stage of research. Different from rigid body motion, there is great motion state randomness of some key features points in aerobics and severe deformation in body. Traditional non-rigid motion reconstruction algorithm concerns the feature point motion parameters are fixed in the calculation process, such as factorization method. However, during exercise, the non-rigid objects cannot guarantee the feature points in the time domain have the same motion parameters [4], even feature points meeting the neighborhood relationships, their motion parameters still may be different. This assumption results in unrealistic of three-dimensional image reconstruction of traditional methods.

2 Correction for the three-dimensional reconstruction of moving image in neighborhood system

2.1Feature points position correspondence

Before adopting correction neighborhood system algorithm, we need to clear the correspondence between feature points of different frames of 3D motion images. The ordered set of feature points' positions is $W = \{1, 2, ..., E\}$, where E is the number of feature points. Generally, the arrangement of feature points is random, which means W is a random position set. The motion parameters of image feature points can be used to mark the moving position of the feature points.

$S_i^t = (x_i^t, y_i^t, z_i^t)^T$ is the 3D spatial coordinates of the *i*th feature point at time t of the non-rigid object. $S_i^{t+1} = (x_i^{t+1}, y_i^{t+1}, z_i^{t+1})^T$ is the 3D spatial coordinates of the *i*th feature point at time t+1 of

the non-rigid object. The moving situation of feature points in 3D spatial can be described by formula (1).

$$\begin{bmatrix} X_i^{t+1} \\ Y_i^{t+1} \\ Z_i^{t+1} \end{bmatrix} = K_i \begin{bmatrix} X_i^t \\ Y_i^t \\ Z_i^t \end{bmatrix} = \begin{bmatrix} a_{i1} & b_{i1} & c_{i1} \\ a_{i2} & b_{i2} & c_{i2} \\ a_{i3} & b_{i3} & c_{i3} \end{bmatrix} \begin{bmatrix} X_i^t \\ Y_i^t \\ Z_i^t \end{bmatrix} \tag{1}$$

k_i is the motion parameter of the ith feature point in 3D space, that is the identification of position i. Then

$$k_i = (a_{i1}, a_{i2}, a_{i3}, b_{i1}, b_{i2}, b_{i3}, c_{i1}, c_{i2}, c_{i3})^T \tag{2}$$

According to the continuity feature of moving objects, the motion parameters of a feature point and some points in its neighborhood is similar. Therefore, comprehensively analyzing motion parameters of feature points in its neighborhood, we can get the marking area of k_i is $H_i = \{k_i \mid i \in E_i\}$.

2.2 Correcting neighborhood parameter

Differences exist in parameters of different feature points and in moving parameters of feature points and neighborhood feature points. Therefore, there is certain error in moving parameters of feature points obtained in 2.1 and the position identifiers of corresponding feature points are invalid. We take these position identifiers as an original location identifiers' set. In iterative analysis, location identifier of feature points are constantly changing, so the identity regions of the feature points are continually being adjusted.

According to formula (1) and (2), the neighborhood of a feature point is determined by the position of the motion parameter in the image. The original image neighborhood is composed by position of the first frame of image feature points. Actually, the position of feature points in 3D moving image has random relationship with motion parameters of feature points. So timely correctness is needed to make sure the moving position of each feature point only has neighborhood relation with the location has the same identity. Usually we adopt variable neighborhood approach. Analyzing the intermediate optimal solution between i the position of feature point and j the position of its original neighborhood system, we obtain prediction error value wc_{ij}, and then calculate the error sum of squares of moving parameters of the two feature points' position by formula (3)

$$\Delta K_{ij} = \sum_{K=1}^{9} \left(K_{im} - K_{jm} \right)^2 \tag{3}$$

If i and j satisfy either condition in (4)

$$\Delta k_{ij} > \beta \quad or \quad wc_{ij} = \max_{i' \in E_i} wc_{ii'} \tag{4}$$

We determine that j is not a neighborhood point of i, and delete j in E_i (the neighborhood system of i). Through (3) and (4), we can obtain all the neighborhood position of i and get E_i' the new the neighborhood system of i.

wc_{ij} in formula (4) indicates determination error. Since the motion of non-rigid objects with a persistent feature, so we need to constantly modify the position of the feature point by determination error function. The new correctness process are: get the position of the object feature points, then correct content of position j in its neighborhood E_i with content of i, and finally use (5) and (6) to calculate error wc_{ij}.

$$
\begin{aligned}
wc_{ij} = \sum_{t=2}^{H} & \left[\left(x_i^t - g\frac{\hat{X}_i^t}{\hat{Z}_i^t} \right)^2 + \left(y_i^t - g\frac{\hat{Y}_i^t}{\hat{Z}_i^t} \right)^2 \right. \\
& + \left[\max\left(0, \hat{Z}_i^t - \left(\hat{Z}_i^{t-1} + Z_{i\boldsymbol{\beta}}\right)\right) \right]^2 + \left[\max\left(0, \left(\hat{Z}_i^{t-1} - Z_{i\boldsymbol{\beta}}\right) - \hat{Z}_i^t\right) \right]^2 \\
& + \left[\max\left(0, \hat{x}_i^t - \left(x_i^t + x_{i\boldsymbol{\beta}}\right)\right) \right]^2 + \left[\max\left(0, \left(x_i^t - x_{i\boldsymbol{\beta}}\right) - \hat{x}_i^t\right) \right]^2 \\
& \left. + \left[\max\left(0, \hat{y}_i^t - \left(y_i^t + y_{i\boldsymbol{\beta}}\right)\right) \right]^2 + \left[\max\left(0, \left(y_i^t - y_{i\boldsymbol{\beta}}\right) - \hat{y}_i^t\right) \right]^2 \right]
\end{aligned} \tag{5}
$$

$$
\begin{bmatrix} \hat{X}_i^{t+1} \\ \hat{Y}_i^{t+1} \\ \hat{Z}_i^{t+1} \end{bmatrix} = \boldsymbol{U}_j \begin{bmatrix} \hat{X}_i^t \\ \hat{Y}_i^t \\ \hat{Z}_i^t \end{bmatrix} + \boldsymbol{T}_j \tag{6}
$$

Let $wc_{ik} = \min_{j \in E_i \text{ or } j=i} wc_{ij}$, the content of k can be taken as that of position i.

3. Results analysis

To verify the effectiveness of the proposed 3D image reconstruction algorithm for aerobics, the paper builds a system to simulate the image sequence through MATLAB version 7.1 and Drect3D 9．0SDK. We choose 50 feature points, according to which simulate 2 continuous image frames as shown in Figure 1. It can be seen that there are 3 forms of motion parameters in the images sequence respectively indicated by U1, U2, U3. And the values of 3 forms of motion parameters are shown in Table 1.

Figure 1 Aerobics image sequence

s_{12}	U2	$\begin{bmatrix} 0.99724925 & 0.0027394127 & 0.073914270 \\ 0.0027394127 & 0.99725643 & -0.073914270 \\ -0.073914270 & 0.073914270 & 0.99452946 \end{bmatrix}$	0.0000009457013

The image sequence according to the experimental results in table 2, 2 and 3 of the frame for three dimensional motion parameter prediction, to obtain the parameters of the predicted values match the table 2. And the system image motion leveled off.

4 Conclusions

Through the analysis above, we can obtain that the number of mistake clusters is reduced and the effectiveness of prediction is enhanced in the aerobics image sequence. The original position of feature points and the number of feature points in each region in the image sequence together determine the amount of mistake clustering. The number of iterations in the experiment is reduced from 140 to 125, indicating that using the corrected neighborhood system to adjust aerobics image sequence simulation system can improve the operational efficiency of the system, increase the authenticity of the three-dimensional image reconstruction aerobics, and achieve good experimental results.

The research of key data classification optimal mining methods for massive data

Li Yinying, Wang Yunze

HeBei institute of communictions, ShiJiazhuang Hebei 050071, China

Keywords: inter-cell classification; mathematical model; fuzzy; convergence

Abstract: The data classification is an important issue in massive data classification. This paper proposes an inter-cell classification algorithm based on phase recombination neighbor points convergence which analyzes the convergence value weights of inter-cell characteristic points and filter the interferences of the minority local optimal characteristic points. The proposed algorithm can promote the convergence of the inter-cell classification data neighbor points. The simulation experiments testify the models by three types of actually collected data sets which illustrate the models have better classification performance.

1 Introduction

The data classification is a hot issue in data mining area. The existing classification algorithm, such as K- centers, is simple and easy to implement. However, the time complexity of the algorithm is high, and it's easy to fall into local optimum [1]. In order to solve this problem, the literature [2] proposed an improved fast K-center classification algorithm which generally divides the data into groups. Then the classification center in each group is optimized. The rough division of the algorithm has no quantitative parameters' analysis and the algorithm may not always find the optimal central sample points. The literature [3] proposed a classification algorithm based on granular computing in which the granular computation is introduced to evaluate the similarity of the samples. The k particles with most similarities are used as the classification center. However, for the sample network data sets with different densities, the similarity thresholds are different and the obtained classification centers are different which cause the classification performance are quite different. The literature [4] proposed the improved particle swarm optimization classification which uses the fitness value of particles to stochastic optimize the particles and uses weighted distances to improve the classification effects of the specific particles. However, the thresholds in the algorithm for different objects will affect the accuracy of the classification and the calculated particles' center may not correspond to the true position of the sample. The literature proposed a density classification method based on the differences in the samples which uses the weighted fuzzy algorithm to classify the differences of the samples. However, the operation efficiency of the algorithm is affected by the differences of the network data attributes. Due to the increasing complexity of network data attributes, the properties can be used to classify will increase greatly. The traditional network data classification algorithm is very sensitive to the initial data center which will result in lower efficiency of the algorithm execution.

2 The classification model for massive data

2.1 The extraction of the classification features

In order to accurately classify the data, the data features should be accurately indexed first. The data indexing is the procedure to extract and integrate the data features so that the data which are need to be indexed will maintain stable within a center range. The specific method is as follows.

（1）The data features are extracted by the following equation.

$$t = \sum_{i=1}^{n} t_i / n$$

In the equation, t_i denotes the single feature of the data, n denotes the amounts of the data features, t describes the final features of the data by calculation.

（2）The key feature t of the data acquired is proofread and adjusted by the following formula to obtain the characteristic deviation $\nabla e(t)$ of the data.

$$\nabla e(t) = t - t_0$$

（3）The characteristic deviation trimming is finished by

$$u(t) = k_p \nabla e(t) + \beta k_i \sum_{j=0}^{k} \nabla e(t) T + k_d (\nabla e(t) - \nabla e(t-1)) / T$$

In the above equations, k_p describes the characteristics transverse trimming, k_i describes the amount of characteristic trimming coefficients, k_i describes the characteristics longitudinal trimming. The tuning of the three parameters will lightly adjust the key feature $u(t)$ of the data need to be indexed to ensure the data in more accurate change period.

2.2 The classification procedure

The inter-cell classification is well applied as the method for massive sample feature data classification. This paper proposes a phase recombination neighbor point convergence inter-cell classification algorithm which analyzes the convergence value weights of the feature data neighbor points, filter the interferences of the minority of local optimal feature data, promote the convergence of the neighbor points and prevent the issue of local convergence.

The proposed algorithm highlights the high efficient convergence of the characteristic neighbor points in the data set which greatly increases the efficiency of the algorithm for data mining. The variation classification coefficients are merged into each data set in the inter-cell and the convergence contribution factors for the overall ranges are expressed by

$$P(k) = \frac{\sum_{i=1}^{k} (\| p - A_i \|)^2}{N \min(\| A_i - A_j \|)^2} \tag{1}$$

If $V(k) \geq 1$, the classes are in inter-cell, otherwise $V(k) < 1$, the inter-cells will be deleted. By the promotion of the neighbor points, the inter-cell classification convergence will be improved. The procedure considering the phase recombination neighbor point convergence is as follows.

（1）The inter-cell selection to determine the total amounts of inter-cells and the feature sets of the initial data. If the data set is m, Let $A_j(L)$ be the center of inter-cell and $j = 1,2,...,k$. The distances to the center can be calculated to determine the amounts and range of the neighbor points.

（2）K samples are selected in the data set. The inter-cell centers of $F(x_i, A_j(L))$ with $i = 1,2,...,m$ and $j = 1,2,...,k$ are initialized to input into the maximum likelihood estimator.

（3）The inter-cell classification algorithm is used to analyze initially, if

$$D(x_i, A_j(L)) = \min\{D(x_i, A_j(L))\} \tag{2}$$

Then $x_i \in \omega_k$ and it's merged into the phase recombination neighbor points to analyze the weights to obtain the each inter-cell mean.

$$C(l) = \sum_{j=1}^{k} \sum_{k=1}^{n_j} (\| p_k^j - A_j(L) \|)^2 \tag{3}$$

（4）Fuzzy selection operator is used to identify the inter-cell thresholds. If the mean is equal to the evaluation value in the previous iteration that is $\| C(l) - C(l-1) \| < \xi$, the program will be terminated. Otherwise, return to step 3 and let $l=l+1$ calculate the new inter-cell center which is expressed by

$$A_j(L+1) = \frac{1}{n_j} \sum_{i=1}^{k} P_i^j \qquad j = 1,2,...,k \tag{4}$$

In the previous procedure, the inter-cell classification algorithm based on phase recombination neighbor points convergence analyzes the convergence value weights of inter-cell characteristic points and filters the interferences of minority of local optimal feature data. The algorithm promotes the convergence of neighbor points which provides new ways for improving the convergence speeds of inter-cell classification.

3 Experiments and results analysis

This paper compares the classification results by proposed method and the traditional classification methods. 300 pieces of Web files are downloaded from the Internet and 3 times of experiments are carried according to different topics.

Table 1 The topics of the experimental test files

No.	Amounts of Files	Topic
1	100	Data type 1
2	100	Data type 2
3	100	Data type 3

The previous files are classified by different topics first in which the some English words are translated into Chinese in the test sets. Each word in the files is divided to obtain the file-word matrix in which each row denotes one file project. They are classified by K-means after dimension reduction with semantic matrix. The classification results by the proposed method are compared with those in the known files to evaluate the accuracy of the classification which is denoted as Ac . It's expressed by

$$Ac(r,s) = n(r,s) / n_r \tag{5}$$

$n(r,s)$ denotes the amount of correctly classified files in some classification cluster, n_r denotes the total amount of files in the classification cluster. The Matlab programs are used to classify the 300 pieces of files by three classification methods-traditional word frequency method, the semantic classification method and the proposed methods in which the word document matrix decomposition time and documents classified time are recorded. The results are shown in Fig. 1

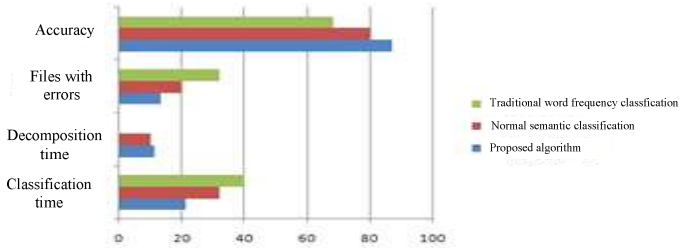

Fig. 1 The performance of different classification methods

In Fig. 1, the classification accuracy is greatly increased in the proposed model while the time consumed for classification is not increased. The results illustrate the advantage of the proposed model.

4 Conclusions

This paper proposes an inter-cell classification algorithm based on phase recombination neighbor points convergence which analyzes the convergence value weights of inter-cell characteristic points and filter the interferences of the minority local optimal characteristic points. The proposed algorithm can promote the convergence of the inter-cell classification data neighbor points. The simulation experiments testify the models by three types of actually collected data sets which illustrate the model has better classification performance.

Keywords: special group line; network hierarchical structure; multiplexing relationship; design

Abstract. The group customer line service has become one of the key businesses for communication operators, and the line PTN technology development currency, the PTN technology application, and the development trend are researched. According to the PTN technology and client group line error correction algorithm, the multi granularity hash correction algorithm is used for data video aware, and when the PTN data is changed fast, the fuzzy block effect happened. The customer line service performance is bad. An improved group customer line correction algorithm is proposed based on PTN technology. The hidden Markov model is used for packet loss rate prediction, and the multiple steps are selected in random, and the data stream iteration algorithm is designed. The tamper detection algorithm is obtained. PTN technology group customer line correction is realized. Simulation results show that the new method can reduce error transmission rate of the PTN group customer line, the customer loss and delay of the data transmission can be controlled, and the peak signal to noise ratio is improved, the error correction performance is better, and it can be effectively applied to communications operator service.

Introduction

At present, with the development of communications technology, customers put forward more and more demand for telecom operators, especially, the requirements of special group line are increasing. Heilongjiang mobile Qigihar branch relies on rich sources of China Mobile, and it provides digital circuit, optical fiber line rental and maintenance services to the enterprises and institutions to the enterprises and institutions. The enterprises and institutions can choose 2Mbps-2.5Gbps bandwidth channel and various interface types, and the security, reliable and high-speed data channel environment is set up, the voice, data, video and other types of businesses are operated based on the service and lines[1].

The common application areas of special group line contain voice special line and data line. Voice special line is he can make the enterprises branch switches interconnected, and connect to the China Mobile switch, quality of voice call, and the cost of long distance is reduced. The data special line can make the enterprises branch network connect, carrying the information interaction, VoIP voice business[2].

According to the current communication service operators, the customer types can be roughly divided into agencies, banks, financial securities type enterprise group, education / campus and hotel / office type. Compared with the general user, the group customers have large volume of business for operators, and business type is complex, quality of service requirement is higher. According to the business development, PTN (Package Transport Network) technology is developed, and the application packet transport network users have a high evaluation, PTN can load the Mobile Backhaul, the QoS services are provided, Metro Transmission Network is converted from TDM to evolved packet network gradually. With the development of the 4G and all the business operation, the IP data services become the main content of city area network, SDH subsided gradually, PTN packet network becomes the core network[3~5].

In this paper, the line PTN technology development currency, the PTN technology application, and the development trend are researched. An improved group customer line correction algorithm is proposed based on PTN technology. The hidden Markov model is used for packet loss rate prediction, and the multiple steps are selected in random, and the data stream iteration algorithm is

designed. The tamper detection algorithm is obtained. PTN technology group customer line correction is realized. Simulation results show that the new method can reduce error transmission rate of the PTN group customer line, the customer loss and delay of the data transmission can be controlled, and the peak signal to noise ratio is improved, the error correction performance is better, and it can be effectively applied to communications operator service.

Technical feature of PTN network hierarchical structure of packet transport network

Packet transport network (PTN) is multi service transport technology based on switched connection orientation, and it not only can bear carrier Ethernet services, but also can support TDM, ATM and IP service. The network reliability satisfied, and OAM is corrected, the network scalability is improved. The QOS transmission with integrated transmission technology based on network attributes is improved. PTN is a level set between the IP service and the underlying optical transmission medium, which is designed according to the sudden and statistical multiplexing transmission for packet traffic requirements. The packet service is the core, and it provides support for multi business. It has efficient bandwidth management mechanism and traffic engineering, and the convenient OAM can make the network management become scalable and high security, etc. It supports TDM service and ATM service, supports clock synchronization and time synchronization, the dynamic control effect is good.

PTN structure is shown in Figure 1, it consists of three layer of PTN network: the virtual channel (VC) layer network, virtual path (VP) network layer and transmission layer network, wherein, the transmission media layer network contains a virtual segment (VS) layer network. For the use of MPLS-TP technology of PTN, VC layer is the pseudo wire (PW) layer, VP layer, LSP layer, VS layer is the LSP section layer. PTN bottom is the transmission medium layer network, the circuit can be adopted by the IEEE 802.3 Ethernet or SDH, OTN connection is used for circuit switching (CO-CS). PTN layer is the customer service layer, it is formed by a single client signals, and customer service layer signal, including PTN network (ETH), TDM (SDH/PDH), ATM, FR, PPP/HDLC etc.

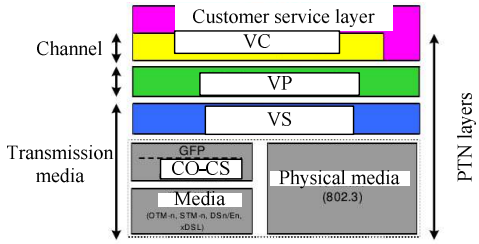

Figure.1 PTN structure

Group customer line correction algorithm design and application based on PTN technology

The special line of group customer has error, and the correcting algorithm is designed, the special line of group customer takes the UDP protocol for the transmission of data packet transmission, the data packets are forced by the link layer of MTU, and the receiving terminal at multilayer nested fragment reassembly in the stream, data stream can cause packet loss and delay, the transmission quality problem should be controlled. The group customer line transmission network structure diagram of PTN technology is shown in Figure 2. Hidden Markov model is designed, eventually realize data transmission and distortion correction.

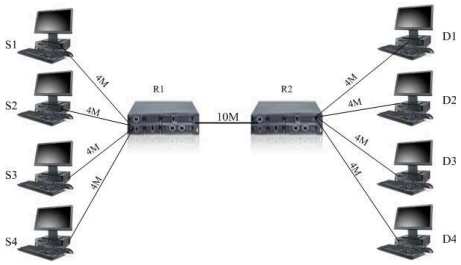

Figure 2. Network structure diagram of group customer special line transmission based on PTN technology

Firstly, the principle of multi granularity hash correction algorithm using video perception is presented, assumed that the structure feature information of network transmission is:

$$V_{ideo}(a_1,\cdots,a_m)=\left(a_i^{j-1}\right)_{i,j=1}^{m} \tag{1}$$

Where, $V(a_1,\cdots,a_r)$ is the block matrix in time domain, $\left(a_i^{j-1}\right)_{i,j=1}^{m}$ is the brightness mean value for each data block, the set of unit step is constructed, and the column orthogonal basis $(a_1,\cdots,a_r)$ and $(b_1,\cdots,b_r)$ is decomposed with $2r$ elements Gauss pseudorandom function, the video sequence with l length is obtained:

$$V(a_1,\cdots,a_m)^{-1}[V(a_1,\cdots,a_m)\,|\,V(b_1,\cdots,b_m)]=[\boldsymbol{E}\,|\,V(a_1,\cdots,a_m)^{-1}V(b_1,\cdots,b_m)] \tag{2}$$

For the PTN data series, the temporal mean brightness is used for hash random overlapped block correction, and the non singular solution is proved, the frequency spectrum characteristic matrix is:

$$(\boldsymbol{A}^{-1})^{(\alpha_1^{-1},\cdots,\alpha_m^{-1})^T}\boldsymbol{A}^{(\alpha_1,\cdots,\alpha_m)}=\begin{pmatrix}\alpha_1^{-1}t_{1,1} & \cdots & \alpha_1^{-1}t_{1,m}\\ \vdots & \ddots & \vdots\\ \alpha_m^{-1}t_{m,1} & \cdots & \alpha_m^{-1}t_{m,m}\end{pmatrix}\begin{pmatrix}\alpha_1 a_{1,1} & \cdots & \alpha_m a_{1,m}\\ \vdots & \ddots & \vdots\\ \alpha_1 a_{m,1} & \cdots & \alpha_m a_{m,m}\end{pmatrix} \tag{3}$$

In the matrix state limited space $V(a_1,\cdots,a_m)^{-1}V(b_1,\cdots,b_m)$, the received stream diversity link layer of MTU high-level code is generated, and the inter layer mode overlapping data are computed, the receiver needs to reconstruct the fragmentation reassembly, the data inter frame prediction and inter layer prediction results respectively are shown as:

$$E_{Tx}(l,d)=E_{(Tx-elec)}(l)+E_{(Tx-amp)}(l,d)=lE_{elec}+l\varepsilon d^{\alpha}=\begin{cases}lE_{elec}+l\varepsilon_{fs}d^2, & d<d_0\\ lE_{elec}+l\varepsilon_{mp}d^4, & d\geq d_0\end{cases} \tag{4}$$

In the formula, d is receiving node distance between the time domain characteristic node and surface sending node, E_{elec} is the energy consumption for each frame of the video data, Using hidden Markov model, a transfer state is expressed as the 2 stochastic process, 5 tuple to describe data transmission sequence model, it is expressed as:

$$\lambda=(X,O,A,B,\pi) \tag{5}$$

Where, X is the hidden state of Markov model, $X=\{x_i,i=1,2,3\cdots,N\}$. O is observation state of group client base on PTN technology, $O=\{o_j,j=1,2,3\cdots,M\}$. A represents the reconstructed state transition probability of matrix, it is a N orders square matrix, $A=\{a_{i,j},0<i,j<N\}$. B is $N\times M$ matrix, and the state transition probability matrix and the confusion matrix are calculated, respectively, they show the tamper detected customer hotline data series and Hashi series, the the mathematical expectation of packet loss rate is:

$$\varepsilon_t(i,j)=\frac{\alpha_t(i)a_{ij}b_j(o_{t+1})\beta_{t+1}(j)}{\sum_{i=1}^{N}\sum_{j=1}^{N}\alpha_t(i)a_{ij}b_j(o_{t+1})\beta_{t+1}(j)} \tag{6}$$

Then, the improved data stream iteration algorithm is designed. The tamper detection algorithm is obtained. PTN technology group customer line correction is realized.

Simulation experiment

In order to test the performance of algorithm for PTN error correction, simulation experiment is taken based on OPNET Modeler 14.5, data size is 11 G, the format of CIF, and the acquisition time interval parameters U and F are10 s and 25 s respectively, the simulation time is 3600 s. GOP structure is IBBPBBPBBP, the traditional method and the new method are taken for the comparison, and the Packet loss rate and the Peak signal to noise ratio are computed for performance compassion in group customer line service and data transmission, the simulation results are shown in Figure 3 and Figure 4. The graph analysis shows that the PPLECA algorithm proposed in this

paper can improve the PSNR about 1.6 dB, the packet loss rate is reduced 0.015, the distortion of information is reduced, and it has good performance in group customer special line correction and application.

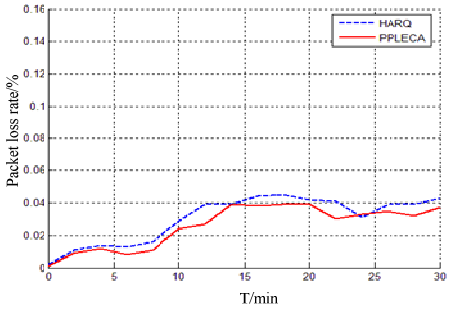

Figure 3 Packet loss rate

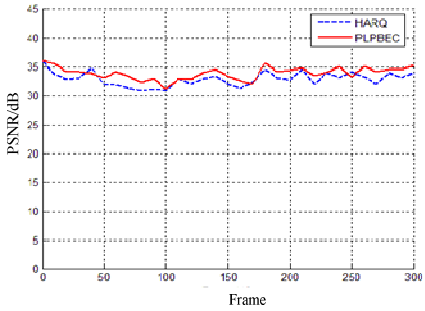

Figure 4. Peak signal to noise ratio

Conclusions

The group customer line service has become one of the key businesses for communication operators, in this paper, and improved group customer line correction algorithm is proposed based on PTN technology. Simulation results show that the new method can reduce error transmission rate of the PTN group customer line, the customer loss and delay of the data transmission can be controlled, it can improve the PSNR about 1.6 dB, the packet loss rate is reduced 0.015, new method can effectively applied to communications operator service

Keywords: key; encryption algorithm, cloud storage; privacy protection

Abstract. The location mobile social networks information privacy protection under the environment of cloud storage and data security of encryption is researched, the traditional data encryption to rank has higher in the length of ciphertext and private key attributes of large matrix, it defines the length of ciphertext data on customer privacy private property and it cannot be revoked. The encryption complexity and security are not good. An improved encryption algorithm based on key attributes of reduced rank agent is proposed, the proxy ReEncryption technology is taken, the ReEncrypt decryption scheme is designed, and private key attributes of bilinear mapping and reduced rank processing is taken, and a communication channel between the user, CSP, trusted third party and data users is established, and the algorithm is obtained. The simulation is taken for testing the customer information data for privacy protection, the simulation results show that it can ensure the length of ciphertext is relatively small, and it has low computational complexity with more security, and it has the very good practical value in encryption communication and privacy protection fields.

Introduction

With the development of computer technology, the development of information technology is developing rapidly, and the network data security problems have gradually emerged, it has become as the bottleneck problem in modern industrial network development[1]. If the security control and defense measures are not reasonable and effective, the network does not have the modernization, information communication capability[2]. Today, the cloud computing and cloud technology are developing rapidly, a lot of data and information are processed through the cloud storage and transmission. At the same time, in the cloud storage terminal, a lot of data leakage and user privacy leakage emerging, for example, in the mobile transform social network, the GPS users upload the location information, but the cloud storage system data protection is weak, the security of data encryption is not good, resulting in of position privacy leak. It causes controversy among the public, Therefore, the research of data information encryption and privacy protection mechanism is important, it has become the hot topic in computer and information technology research areas.

Data encryption is an important mean in network information access and security control, after so many years development[3], the traditional intrusion has been able to protect some intrusion, , but for a new type of network intrusion, the protection effect is not good. So, in the modern information technology development trend, it needs to continuously improve the network intrusion of private key encryption scheme, with the deeper levels of encryption, the network data security is protected, the secret information will not be stolen. The traditional data encryption algorithm uses the attribute length ciphertexts encryption scheme, the private key of user is defined as the length of ciphertext, and the decryption plaintext matrix is constructed with high ranks and high dimensions, which leads to computational complexity is very high, the encryption effect is not good[4].

In view of the above problems, an improved encryption scheme is proposed based on key attributes of reduced rank agent[5], the proxy ReEncryption technology is taken, the ReEncrypt decryption scheme is designed, and private key attributes of bilinear mapping and reduced rank processing is taken, and a communication channel between the user, CSP, trusted third party and data users is established, and the algorithm is obtained. The GPS supplier carries network is taken as the example, and the social network privacy protection system and algorithm are constructed, and the data encryption test is taken, it shows that the algorithm has excellent performance in data encryption and privacy protection.

Encryption model design of secure cloud storage

In the information data encryption of user mobile terminal equipment, it needs to establish a correlation system, the encrypt data characteristics are correlated. We need to have a large number correlation characteristics as the input raw data, on the basis of this, a large number of trainings are taken, and the data features are extracted, finally, the data characteristics correlation processing is completed.

The cloud storage security model of information data is divided into four parts, including the CSP user authorization center, cloud storage server, GPS information data owners and data user. In the model design, the user information cloud storage data attribute matching management uses scalar time series, the ciphertext is read, in order to realize the adaptive cancellation properties, the position change operation center is required, and the proxy re encryption key is authorized as the private key storage institutions. According to the user and level, authentication mechanism of cloud storage data terminal ciphertext is divided into three levels respectively.

(1) The authorization center of user information data. Authorization center is similar to the CA authentication mechanism, including the registration management server, key generation and key distribution server hardware configuration, in the implementation of encryption and authentication, the private key authentication properties are called for authorizing the Setup replacement algorithm, encryption attribute is generated. Through master key MSK, the encrypted ciphertext is obtained, and it is written to the HDFS framework. The secret key SK_L is generated and the serial number is ser.

(2) The data information owner. As the data owner, user privacy information need to be accessed, and the custom access structure is W, the Encrypt algorithm is designed to obtain the private key attribute CT. CT is put in the cloud storage server to establish the new CHUNKS.

(3) The data users. Data users is put in the GPS service platform terminal, it is at the bottom of the cloud storage network node, by authorization center, MooseFS distributed file system is set copy files, and the encrypted ciphertext CT is accessed, through private property reduced rank proxy encryption algorithm, open source distributed file system is designed, and the adaptive cancellation property ciphertext and change is realized.

Algorithm design and key technology

On the basis of user information data encryption model design as above, the encryption algorithm is improved, and the algorithm is described as follows:

Firstly, the data model is established, assumed the cloud storage information series is constituted by two order sets with p distributed attributes, it is expressed as: $\Omega = \{att_1, att_2, \cdots, att_n\}$.

Where, the order is p, the value of the user information data in attribute att_i can be expressed as: $A_i = \{v_{i,1}, v_{i,2}, \cdots, v_{i,n_i}\}$.

Using adaptive attributes revocation method to obtain the data of mobile social network, the new private key of user authorization information center is: $L = [L_1, L_2, \cdots, L_n]$.

Where, $n_i = |A_i|$, the formula shows that when the user access the authorization center of network information reception, an open source distributed file system should be established, assumed that $L = [L_1, L_2, \cdots, L_n]$ is the private key attribute set, the key attribute certification is recalled, the access codes of certification center is $W = [W_1, W_2, \cdots, W_k]$. By calling the writing position, the bilinear mapping of access strategy in the key attribute is represented as: $e: G \times G \to G_1$. The agent re-encryption technology is designed through the scheme, ReEncrypt decryption scheme is designed, the agent re-encryption key is computed, and the bilinear mapping and reduced rank processing are taken, the computational complexity can be reduced, the process is divided into the following steps:

(1) $Setup(1^k)$: security key parameters are set, and the length of ciphertext is input, the management services are selected in random, defined $h \in G$ and $y \in Z_p$, $t_{i,j} \in Z_p (i \in [1,n], j \in [1,n_i])$.

In the cloud storage data authorization center of user information, the authorization center computed: $T_{i,j} = g^{t_{i,j}} (i \in [1,n], j \in [1,n_i])$, where, $Y = e(g,h)^y$. The private key attributes of parallel network is computed, and formula is: $MPK = (e,g,h,Y,T_{i,j}(i \in [1,n], j \in [1,n_i]))$.The master key of registered management server is: $MSK = (y, t_{i,j}(i \in [1,n], j \in [1,n_i]))$. Write data information by MooseFS, the initial sequence number is obtained, it is: $ser = 1$, and the authorization center is stored as (ser, MSK).

(2) $KenGen(MSK, L)$: The mobile position change information of cloud storage system is input into the user attribute set, because $r \in Z_p$, we calculate h^{y+r}, when $\forall v_{i,j} \in L$, we get $D_{i,j} = (T_{i,j})^r$. The private key of user information is returned:

$$SK_L = (ser, h^{y+r}, \forall v_{i,j} \in L : D_{i,j} = (T_{i,j})^r, g^r, L) \quad (1)$$

(3) $Encrypt(MPK, M, W)$: The information to be encrypted is generated, and access strategy is randomly selected, it is $s \in Z_p$, set: $C_1 = MY^s$, $C_2 = g^s$, and $C_3 = (h^s, \forall v_{i,j} \in W : X_{i,j} = (T_{i,j})^s)$, the attribute matrix of private key is reduced in rank, the output ciphertext is expressed as:

$$\frac{Me(g,h)^{ys} e(g^r, h^s g^{sp})}{e(g^s, h^{y+r}) e(g^s, g^{rq})} = \frac{Me(g,h)^{ys} e(g,h)^{rs} e(g,g)^{rsp}}{e(g,h)^{ys} e(g,h)^{rs} e(g,g)^{rsq}} \quad (2)$$

In the formula, $p = \sum_{v_{i,j} \in W} t_{i,j}$,. $q = \sum_{v_{i,j} \in AS} t_{i,j}$. If the system has attribute update and revoke, the authorization center calls $ReKeyGen$ and $ReKey$ algorithms, the agent re-encryption key and the key corresponding to users are generated. Last, the ciphertext is written as $CT = (ser, C_1, C_2, C_3, W)$, it is uploaded to the cloud storage server. Introduced CSP and the trusted third party, the communication channel between the user, CSP and the trusted third party is established. Check the CT sequence number between the ciphertext and user are consistent, if they are not consistent, the CT is outputted directly, and the redundant bits are processed with retransmission. According to $v_{i,j} \in \beta$, and $v_{i,j} \in W$, compute: $C_3' = (h^{sm}, \forall v_{i,j} \in W : X_{i,j}' = (T_{i,j})^{sck_i})$. Where, $m = \sum ck_i$. Finally, output re-encrypted ciphertext: $CT' = (ser+1, C_1, C_2, C_3', W)$.

Through the above encryption scheme, the data encryption storage and transmission of the position change in social network are realized in the cloud storage terminal, the algorithm is improved.

Simulation test

In order to test the performance of the algorithm, the simulation experiment is take for private key attribute encryption algorithm realization, it is taken based on the Matlab simulation software, the original data are samples from the GPS supplier, the collection period is from 2010 January to 2013 January, in order to protect the privacy and security with position changes in the network, this algorithm is used to encrypt the information, to improve safety performance data in GPS cloud storage data management system, the experimental environment is shown as: Pentium (R) 4 CPU, 3.00GHZ, PC 512M memory, the parameters are set as: $t_{\max}$=1000, M=100, l=256, p_m=0.043, p_c=0.35. In the simulation test, the evaluation parameters such as public parameter (MPK), the master key (MSK), the user private key (SK) and the encrypted message (CT) size are computed for comparison with 4 different algorithms, and the simulation results are shown in Figure 1~4. The results show that using this method, the computation complexity s much lower than the conventional encryption schemes, and the parameters of encryption is better than the traditional method, and this is because this method ensures the length of ciphertext is relatively small and system attributes revocation. Through the cloud storage data encryption scheme, it is applied to the GPS mobile network data information management, and it can effectively protect user privacy security.

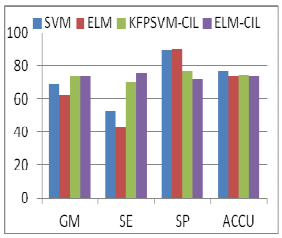

Figure 1. MPK results

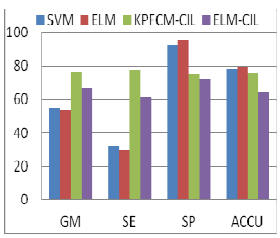

Figure 2. MSK result

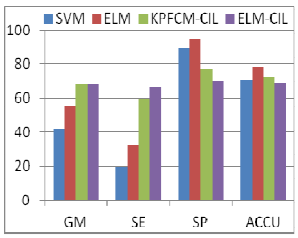

Figure 4. CT results

Conclusion

In this paper, the location mobile social networks information privacy protection under the environment of cloud storage and data security of encryption is researched, an improved encryption algorithm based on key attributes of reduced rank agent is proposed, the data encryption storage and transmission of the position change in social network are realized in the cloud storage terminal, the algorithm is improved. The indexes as MPK, MSK, SK and CT are taken for evaluation, the simulation results show that it can ensure the length of ciphertext is relatively small, and it has low computational complexity with more security, and it has the very good practical value in encryption communication and privacy protection fields.

Keywords:network intrusion detection;support vector machine;model parameters;genetic algorithm

Abstract. Intrusion detection is an emerging area of research in the computer security and networks with the growing usage of internet in everyday life. Parameters selection of support vector machine is a important problems in network intrusion detection. In order to improve network intrusion detection precision, this paper proposed a network intrusion detection model based on parameters of support vector machine (SVM) by genetic algorithm. The performance of the model was tested by KDD Cup 99 data. Compared with other network intrusion detection models, the proposed model has significantly improved the detection precision of network intrusion.

INTRODUCTION

With the increasing popularity and complexity of computer network intrusion, intrusion detection has received more and more attention for the security of computer systems[1].

There are generally two intrusion detection methods: misusing detection and abnormal detection. The foundation of misusing detection is constructing an attack conduct feature base and use feature matching method to confirm attack affairs; Abnormal detection is based on constructing normal conduct model and determine whether the subsequences deviates from the normal conduct model to make intrusion detection[2]. The former researchers injected many kinds of machine learning methods into IDS research, such as neural net, genetic algorithm, etc[3,4]. However, these traditional intrusion detection methods always need perfect and quantity of training data to acquire desirable detection properties and the training time is always too long. Unfortunately, the data sample we can acquire in the intrusion detection field appears variable; small and with high dimension and can not satisfy this kind of requirements. These data sets are too difficult for the traditional machine learning algorithms to deal with [5]. Support vector machines (SVM) is a machine learning method derived from the statistical learning theory, it has shown growing popularity and has been successfully applied to network intrusion detection. SVM provides a generic mechanism that fits the hyper plane surface to the training data using a kernel function. When SVM is used to establish network intrusion detection model, the parameters that should be selected include penalty parameter C and the kernel function parameters.

In order to improve network intrusion detection precision, this paper proposed a network intrusion detection model (GA-SVM) based on SVM parameters by genetic algorithm, and the performance of GA-SVM is tested by simulation experiments using KDD-DUP-99 data sets.

PROPOSED SCHEME

A.Principle of SVM

Let the given training data sets be represented by(x_i, y_i), i=1,2…,n, where $x_i \in R^d$ is an input vector, $y_i \in R$ is its corresponding desired output, and n is the number of training data. In SVM a linear function is constructed:

$$f(x) = \omega^t g(x) + b \tag{1}$$

Where, ω is a coefficient vector and b is a threshold.

The loss function is defined as:

$$\begin{aligned} L^{\varepsilon}(x, y, f) &= |y - f(x)|_{\varepsilon} \\ &= \max(0, |y - f(x) - \varepsilon| \end{aligned} \tag{2}$$

Where, ε is a positive parameter that allows approximation errors smaller than ε. The empirical risk is

$$\mathrm{R}_{emp}(\omega)=\frac{1}{n}\sum_{i=1}^{n}L^{\varepsilon}(y-f(x_i)) \tag{3}$$

Other than the ε-intensive loss, SVM tries to reduce the model complexity by minimizing $|\omega|^2$. This can be described by slack variables ξ_i and $\hat{\xi}_i$.. Subsequently, the SVM approximation is obtained as the following selection problem [9].

$$\begin{aligned}&\min \frac{1}{2}|\omega|^2+C\sum_{i=1}^{n}(\xi_i+\hat{\xi}_i)\\&s.t.\\&\begin{cases}y_i-f(x_i)\le\varepsilon+\xi_i\\f(x_i)-y_i\le\varepsilon+\hat{\xi}_i\\\xi_i,\hat{\xi}_i\ge 0\end{cases}\end{aligned} \tag{4}$$

Where, C is a positive constant to be regulated. By using the Lagrange multiplier method, the minimization of formula (4) causes the problem of maximizing the following dual selection

$$\begin{aligned}\max &\sum_{i=1}^{n}y_i(\hat{\alpha}_i-\alpha_i)-\varepsilon\sum_{i=1}^{n}y_i(\hat{\alpha}_i-\alpha_i)-\\&\frac{1}{2}\sum_{i,j=1}^{n}(\hat{\alpha}_i-\alpha_i)(\hat{\alpha}_j-\alpha_j)K(x_i,x_j)\end{aligned} \tag{5}$$

Where, $\hat{\alpha}_i$ and α_i are Lagrange multipliers, and kernel $K(x_i,x_j)$ is a symmetric function, here the Gaussian function is used as kernel

$$K(x,y)=\exp(-\frac{\|x-y\|^2}{2\sigma^2}) \tag{6}$$

Then the approximation function is represented by Lagrange multipliers, namely

$$f(x)=\sum_{i=1}^{P}(\hat{\alpha}_i-\alpha_i)k(x_i,x_j)+b \tag{7}$$

SIMULATION RESULTS

A.Experiment data

The experiment data are from KDD Cup 99 which sets contains 7 weeks' internet flow rate, about 5,000,000 connecting records and has four categories of attacks: DOS: Denial of service, R2L: Unauthorized access from a remote machine, U2R: Unauthorized access to local super user privileges, Probing: Surveillance and other probing.

B.Comparison models and evaluation criterion

In order to make the detection results of GA-SVM comparable and persuasive, two comparison model are chosen, SVM1: which the parameters of SVM are selected randomly, and SVM2: the he parameters of SVM are selected grid search. The models' performances are evaluation by the three measures called precision, recall, and train times. Precision refers to how the experimental values and observed values are close to each other.

$$precision=\frac{TP}{TP+FP} \tag{8}$$

Where, *TP*, *FP* are the number of True Positives and False Positives respectively.

Recall is defined as the fraction of relevant documents that are retrieved.

$$recall=\frac{TP}{TP+FN} \tag{9}$$

Where, *FN* is the number of False Negatives respectively.

C.Data scaling

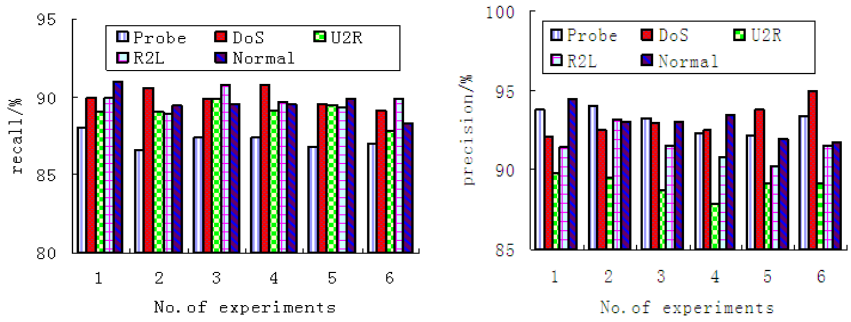
To avoid numerical difficulties during the SVM training, each feature can be linearly scaled to the range [0, 1] by formula (10).

$$x_i^{'} = \frac{x_i - \min(x_i)}{\max(x_i) - \min(x_i)} \tag{10}$$

Where, x_i is original value, $x_i^{'}$ is scaled value, max(x_i) obtains the max value of the feature value, and min(x_i) is low bound of the feature value.

D.Results and analysis

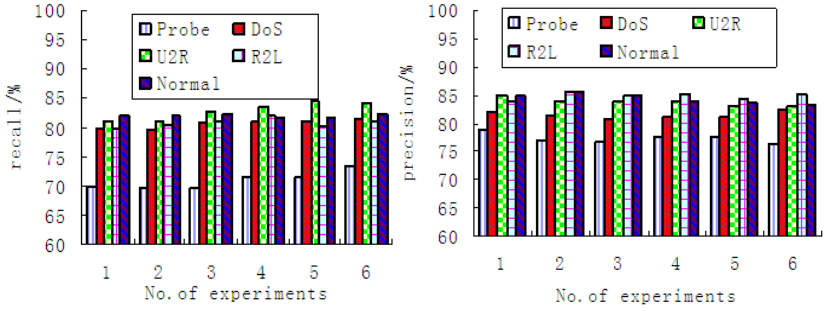
The optimal parameters of SVM are used to establish to the network intrusion detection model, the detection results are shown in figure2. We can see from figure 2 that the GA-SVM can obtain high network intrusion detection precision and recall, and it is an effective network intrusion detection model.



(a) the detection recall (b) the detection precision

Figure2 The detection results of GA-SVM

The detection results of c*omparison mod*els SVM1 and SVM2 are shown in figure 3~4. The experimental results in figure 2~4 are analyzed and conclusion can be obtained that Compared the SVM1, GA-SVM has improved detection precision and recall of network intrusion, so the performance of GA-SVM can be greatly improved to ensure the safe of the network.



(a) the detection recall (b) the detection precision

Figure3 The detection results of SVM1

Figure4 The detection results of SVM2

CONCLUSIONS

Nowadays improving the ability of IDS to detect attacks accurately is the primary problem facing in IDS manufacture. Good setting parameters of SVM are very crucial for network intrusion detection model, and the paper proposed a network intrusion detection model based on SVM parameters by genetic algorithm. The simulation results showed that GA-SVM has a better performance and has wide application prospect in the field of network security.

Keywords: active shape model; feature extraction; texture model; face modeling;

Abstract. The active shape model (ASM) is a statistical parametric model, which is mainly used in image feature extraction. On the basis of the analysis of the original ASM texture model, a new texture modeling method was proposed in this paper. The improved method fully utilized the gray level information of adjacent points in the neighborhood of sampling points, improved the original face modeling method which only used the one-dimensional gray information with model matching accuracy problems. The experiments on Weizmann face database Indicate that, the improved method can obviously improve the feature point positioning accuracy, and accelerate the speed of face model fitting.

Introduction

With the rapid development of computer graphics, facial modeling based on computer graphics developed to the intelligent accurate direction. Face modeling is just to build local texture model and do the face image restoration by means of the accurate facial feature extraction. On the basis of the feature points, the face recognition and computer vision was realized[1]. Study of face modeling and recognition involves image processing, pattern recognition, cognitive science, artificial intelligence and other related science, and now face modeling is widely applied to the field of artificial intelligence, identification, security system design. The research and design of face modeling algorithm based on the local texture model constructing have become the subject of computer image processing topic [2].

In recent years, face feature extraction method based on the statistical model have developed widely. There are two kinds of method typically, one is the active shape model and another is active appearance model. The active shape model (ASM) [3] was proposed by T. F. Cootes in 1995. At the beginning it was put forward to solve the problem of medical image. ASM directly benefits from the variable model of ACM [4], which can extract the target feature points of external shape, and also can accurately extract the target internal shape and feature point. In 1998, Cootes et al. proposed the active appearance model (AAM) based on the ASM algorithm [5]. This model is mainly to add texture model based on shape model ASM, it not only uses the shape information of objects and makes full use of texture information of the target object. At present, these two methods are widely used, and ASM is better than AAM in the location accuracy of feature points, while the AAM is better in image texture matching.

The original ASM method only consider the gray correlation information between a point and its neighboring points, but ignore the standard gray information of other point fixed near the neighborhood in the establishment of local texture model. On the basis of the research of the improved algorithm before, a weighted algorithm is proposed for the sampling points based on neighborhood. First we find a standard around the adjacent point of normal direction, then sample the feature points along the normal direction, obtain the gray information point of the current sampling by weighting method, and we establish a robust local texture model finally. The experiments conducted on the Weizmann face database verified the matching performance of the improved algorithm.

Active shape model

ASM is a feature matching algorithm based on the statistical parameter. The idea is that describing shape with some key feature points through the selection of a set of training samples, and

then constructing the statistical shape model and local contour model on the basis of shape information, finally finding the minimum point of Mahalanobis distance according to the matching principle of statistical model. The shape parameters of ASM model can change adaptability to characterize the shape of uncertainty. ASM algorithm mainly includes three steps: feature point calibration, statistical model establishment and model matching.

A. Feature point calibration

In ASM, an image shape was described and characterized through the calibration point. A set of calibration feature points formed a set called point distribution model (PDM). The calibration points were general selected in the points which can effectively describe the object contour features local, such as corner points, boundary point, line T and so on. In PDM, a human face images can be represented as:

$$s = (x_1, y_1, \cdots x_i, y_i, \cdots x_v, y_v)^T \tag{1}$$

Wherein, (x_i, y_i) is the two-dimensional coordinate of feature point i in the PDM model, and v is a face image calibration point number.

B. Statistical model establishment

In ASM, the statistical model includes statistical shape model and statistical texture model. We first establish a statistical shape model, and eliminate the effects of non shape factor through the shape transformation and alignment, then do the statistical analysis of the training set between shapes, and finally establish a parametric statistical pattern contour model. Principal component analysis (PCA) is a fast, linear transformation method, the maximum variance conditions to find the best method which can reflect a kind of transformation and projection method of original data. A statistical model was established using PCA and the process is shown as:

(1) Calculation of the average shape of face set:

$$\bar{s} = \frac{1}{N}\sum_{i=1}^{N} s_i \tag{2}$$

(2) Calculation of the corresponding covariance matrix:

$$C = \frac{1}{N-1}\sum_{i=1}^{N}(s_i - \bar{s})(s_i - \bar{s})^T \tag{3}$$

(3) Calculation of the characteristic value λ and characteristic vector p of the covariance matrix ,and the characteristic value was put in descending order, the largest characteristic vector $[\lambda_1, \lambda_2, \cdots \lambda_n]$ was selected as such rules:

$$\frac{\sum_{i=1}^{n}\lambda_i}{\sum\lambda_i} \geq \eta \tag{4}$$

Wherein, η is the proportion of first n numbers in all characteristic value, which has a selection in 95%~98%.

(4) Characteristic vectors $p = [p_1, p_2, \cdots p_n]$ corresponding to the characteristic value of n numbers are selected to establish a linear statistical model:

$$s = \bar{s} + Pb \tag{5}$$

Wherein, $\bar{s}$ is the mean shape, P is to convert the vector, b is the shape parameter vector. To avoid over fitting phenomenon, b is limited in:

$$-3\sqrt{\lambda_i} \leq b_i \leq 3\sqrt{\lambda_i} \tag{6}$$

For the point j in the image i, in the normal direction of the point and its neighboring points on the line, we sample k points along the sides which form the gray vector of the point:

$$y_{ij} = [y_{ij,1}, y_{ij,2}, \cdots, y_{ij,2k+1}]^T \tag{7}$$

The local contour model of the training set image can be established according to the method of the sampling gray information, and the average gray vector and covariance matrix are expressed as follows:

$$\overline{y_j} = \frac{1}{N}\sum_{i=1}^{N} y_{ij} \tag{8}$$

$$C_j = \frac{1}{N}\sum_{i=1}^{N}(y_{ij} - \overline{y_j})(y_{ij} - \overline{y_j})^T \tag{9}$$

C. Model matching

The characteristic vectors of local statistical model can be obtained from each calibration point through the above gray sampling method. In ASM matching process, the Mahalanobis distance between the designated local contour and the local contour model and training images are calculated, and the best matching point is the candidate of minimum Mahalanobis distance. For the input test image of a feature point, the Mahalanobis distance is computed by the method of sampling gray:

$$d = (y_j - \overline{y_j})^T C_j^{-1}(y_j - \overline{y_j}) \tag{10}$$

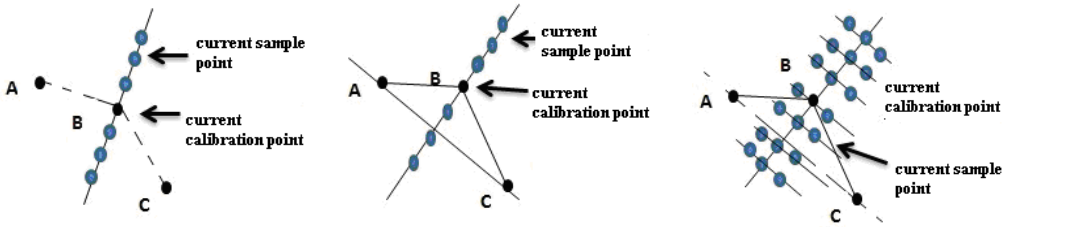
The improved active shape model

The above optimization method has improved ASM matching performance, but through the analysis, the sampling gray points in the normal direction was only took in the direction normal to the sampling point information, and did not consider each point and the neighborhood of point of information. Because of the great effect of the sampling points around the point information of the sampling point, so the points were sampled in the normal sampling point neighborhood in this paper, which can make full use of gray level information of each sampling point neighborhood. This method can better get the texture information of feature point and the neighborhood, so as to provide reliable basis to extract more accurate and face location the key feature points.

The improved method proposed in this paper was specifically shown in Figure 1(b), two gray points were sampled on the nearby of the normal sample points, which were sampled in the vertical direction of normal gray. Suppose the two new sampling points around B are B_r and B_l respectively, the new gray information of point B can be expressed as:

$$Y_B = \alpha . y_{B_r} + \beta . y_B + \gamma . y_{B_l} \tag{11}$$

Wherein, Y_B is the new gray information of point B, α, β, γ are the weight parameters. We often choose the weighting parameters as $\alpha = 0.5, \beta = 0.25, \gamma = 0.25$.

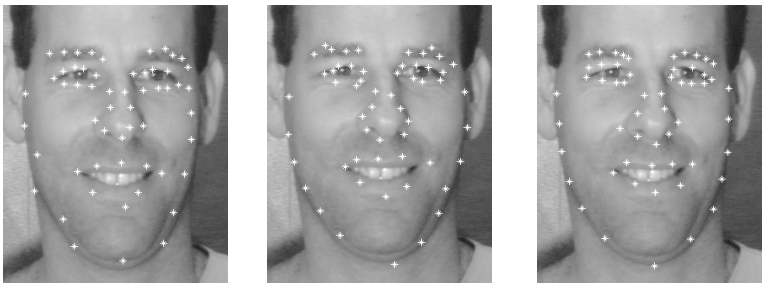


(a) Original method (b) Optimization method (c) Improved method

Figure 1 Building method of local texture model

Experimental results and analysis

The experiment was taken based on the Weizmann face database. This database contained 28 individual, each person has 5 kinds of attitude, 3 lights, 3 kinds of expression. We selected 24 individual, each person had 3 kinds of attitude and 3 lights as training. Calibration feature points on each face were 56. We use different texture model experiment method of constructing ASM, respectively the original method, the optimization method and the improved method. The matching results of the three different texture model construction methods of ASM feature points were shown in Figure 2. Something can be seen from the chart, the original method will bring some errors, and the optimized model can improve the accuracy of feature points with some not well accurate positioning, but the improved method can significantly improve the feature point positioning precision of the ASM.



(a) Original method (b) Optimization method (c) Improved method

Figure 2 Matching results of ASM

Comparison of ASM feature point position of different texture modeling method is given, the average error after 10 times of iterative calculation, the lifting percentage is compared with the original method. It can be seen from the table data, the improved method is better than the original method and optimization method, the improved method has the characteristics of lower matching error, while a higher percentage of the ascension, which can reach 11.69%.

Conclusions

Active shape model has been widely used in face recognition as a statistical modeling method based on parameterization. Local texture modeling method in traditional ASM only took gray information between adjacent features into consideration, which will bring large errors to the face modeling. Based on the analysis of the existing optimization algorithm, and a new method of modeling of local texture with full use of adjacent gray information between sampling points was proposed. The experimental results on Weizmann face database show that, the improved method can improve the location accuracy, reduces the matching error. The fitting rate of the model is improved greatly. Experimental results show that the improved method is very effective in the face modeling application.

Keywords: constraints; information inquiry; database optimization

Abstract. The design of data mining system in database is researched. Vast amounts of information contained in the database, and the data show the diversity of characteristics, resulting in lower efficiency of data mining in database, which database brought greater difficulties to information query. To avoid these shortcomings, database performance optimization method based on cloud computing is proposed. The model of cloud computing data relationship is established to describe the connection between related data inthe database, thus providing the basis for data query. The load state of data nodes is calculated to enable rapid information inquiryin the database. Experimental results show that using this algorithm to optimize data inquiry in database can improve the efficiency of informationinquiry indatabase effectively.

Introduction

With the continuous development of information management technology, the application scope of database are increasing[1]. Information from different fields are integrated together to form a complete database, which can provide valuable information for different industries [2]. Therefore, the database inquiry method, has become a hot issue in the field of information management, and attracts the attention of many scholars [3]. Currently, the main database inquiry methods include database inquiry methodbased on cloud computing, database inquiry method based on spectral clustering algorithm and database inquiry method based on K -means clustering algorithm [4]. Among them, the most commonly used database inquiry method is based on cloud computing. Because the database inquiry method has a wide range of applications, it attracts the attention of many scholars, and becomes a research focus [5, 6].

The optimization methodfor data mining of database

1. A. establishment of cloud computing mathematical relationship model

The number of nodes in the database is set to be p , a data network is constituted by all data nodes , which can be described by the following equation :

$$T = \{t_j \mid 1 \le j \le p\} \tag{1}$$

The data set composed of information from all of the data described by $E(t_T)$, the amount of data information on the node is $n_j = \mid E(t_j) \mid$. Nodes in neighborhood range of specified node t can be describedwith $N(t)$.

The nodes in database is set toconstitute a distributed data network, the set consisted by data in the nodes is $DD = \bigcup_{j=1,2,\ldots,p} ed_j$. ed_j can be used to describe the j -thnode in the database , DD is bandwidth between different nodes in the data network , which can be calculated using the following formula :

$$C = \begin{pmatrix} c_{11} & c_{12} & \cdots & c_{1|ed_p|} \\ c_{21} & c_{22} & \cdots & c_{2|ed_p|} \\ \vdots & \vdots & \cdots & \vdots \\ c_{1|ed_1|} & c_{1|ed_2|} & \cdots & c_{|ed_p||ed_p|} \end{pmatrix} \tag{2}$$

The above formula is required to meet the following conditions:

$$\begin{cases} \forall j,k = 1,2,...,|ed_p| \\ j \neq k \end{cases} \tag{3}$$

Wherein, c_{ij} is the bandwidth value between nodes ed_j and ed_k in the distributed data network.

All the data structures in the database are set to be same, the number of attributes for each data object is n, then the following equation is applied to describe the data elements in the database :

$$ne = (F_1, F_1, \cdots, F_n) \tag{4}$$

Wherein, F_j is the data set composed of all the attributes in the database, and can be describedwith $F_j = \{F_{j,1}, F_{j,2}, \cdots, F_{j,\delta_j}\}$. Therefore, the data object with same data structure can be described by the following equation:

$$F(e) = (F_{1,k_1}, F_{2,k_2}, \cdots, F_{n,k_n}) \tag{5}$$

The related data in the formula required to meet the requirements of the following conditions: $F(e) \in F_1 \times F_2 \times \cdots \times F_n$

Two objects y and z are randomly selected in the database, assuming that the two nodes meet the following requirements, which means that the two nodes are similar.

Rule 1: Node y and z have same value on the F_j property;

Rule 2: similarity attribute of nodes y and z is greater than the similarity threshold, the threshold is usually a constant.

And provided with the corresponding data center of y and z respectively, by the following equation can describe the relationship between two nodes:

$$\begin{aligned} &TP(q,r,F_n,p_j) \to \exists y \in E(q), \exists z \in E(r) \\ &y \neq z \wedge \varpi_{F_j}(F(y)) = p_j \wedge \varpi_{F_j}(F(z)) = p_j \end{aligned} \tag{6}$$

The relationship between above two data centers can be described by the following equation:

$$FP(q,r,y) \to r \neq y \in E(q) \wedge y \in E(r) \tag{7}$$

A data node y is randomly selected in database, the data set constituted of all the equivalent can be described by the following equation: $FPT(q,y) = \{r \mid q \neq r \wedge y \in E(q), z \in E(r)\}$ (8)

2. B. implement database data mining

With cloud computing querying database information, node loads are needed to be tagged in the equivalent node data collection. In the designated time period u, the number of requests for data objects y in data node q is expressed by $M(q,y,u)$,the following equation can be employed to describe the load information of node q :

$$D(q,u) = (M_d, M_v, M_m) \tag{9}$$

M_d, M_v and M_m are load information, the maximum and minimum load capacity of the data node q separately. The following equation is used to describe the overload and under load information of data node:

$$\begin{aligned} Fm(q,y,u) &= \frac{(M(q,y,u) - M_v(q))}{M_v(q)} \\ Ol(q,y,u) &= \frac{(M_m(q) - M(q,y,u))}{M_m(q)} \end{aligned} \tag{10}$$

Combining the above equations, the following formula can be obtained, which can accurately describe the load information data set of equivalent nodes:

$$\begin{aligned} &D(q,y) = \{(r,F,P) \mid r \in F(q,y) \\ &F = Fm(q,y,u), O = Ol(p,x,t)\} \end{aligned} \tag{11}$$

In the above formula, ideally, the load state of data node is $M_m < M_d < M_v$, if $M_d \geq M_v$, the data node is overloading , otherwise , the data node is in idle state.

Experimental results

In order to verify the effectiveness of the proposed method, an experiment is processed. Experimental environment is Visual C + +6.0.

In the process of data mining in database, the related state of experimental sample data can be expressed by the following table:

Table 1 Table of experimental sample data

Data classification	data attribute	attribute data number (ten thousand)
1	Oil	1.2
2	Liquor	2.4
3	Soy source	1.6
4	Automotive	1.7
5	Dairy	2.2
6	Red wine	2.4
7	Cotton	1.8
8	Weather	2.3
9	Industry	2.5
10	Healthcare	0.9

For data with different attributes, traditional algorithms and improved algorithms are employed for data mining separately, the mining results precision can be expressed by the following table:

Table 2 Comparison of precision obtained from different algorithms

Categories of data	Precision ratio（%）	
	Traditional algorithm	Improved algorithm
1	88.7	92.1
2	86.5	93.2
3	88.2	91.9
4	87.2	92.4
5	88.6	93.1
6	85.7	94.2
7	86.2	93.2
8	88.1	91.8
9	86.7	92.4
10	88.2	93.6

According to the data in the above table, with the improved algorithm for database data mining, precision rate is much higher than traditional algorithms, which can provide more accurate data mining results for the database inquiry.

Conclusion

This paper presents a method for optimizing database performance based on cloud computing. The relationship between cloud computing modelsis established to describe the connection between the database data, thus providing the basis for data inquiry. The load state of data nodes are calculated toenable rapid query for information in the database. Experimental results show that this algorithm used for optimizing the database inquiry, can improve the efficiency of database information inquiry.

Keywords: Coherent light; signal processing; compensation; algorithm.

Abstract. In order to use minimal cost to compensate signal distortion caused by fiber dispersion and carrier phase noise etc, this paper mainly puts forward 2 different self-adaption compensation algorithms in algorithm part of digital signal processing, through test and comparative analysis, it indicates that the performance of the best matching and the nature expression based on GCT is the best.

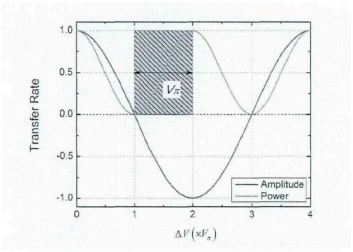
Introduction

With the gradual pursuit of photo-communication on larger bandwidth, longer distance and higher receiver sensitivity, so communication technology of digital coherent light appears as time requires. Communication technology of digital coherent light can not only increase receiver sensitivity, at the same time it can also get the whole light field information, so that it the incomparable advantages that conventional intensity modulation / direct detection (lM/DD) system can not be compared. The repaid development in communication technology of digital coherent light is profits from high-speed development of new modulation technology and DSP. New modulation technology increases availability of frequency spectrum through flexible way of information loading, with the enhancement of DSP in operational speed, the communication system of digital coherent light has become one of the powerful competitors of optical network in the next generation. This paper mainly puts forward different algorithms of self-adaption dispersion compensation in algorithm of digital signal processing, they are respectively based on technology of time-delay sampling and deviation test technology of symbol sampling. Compared with other algorithms, the algorithm based on time-delay sampling technology can provide larger dispersion scanning step and comparative estimated precision, while algorithm based on sampling deviation test can get comparative or higher estimated precision by fewer symbols.

Communication System of Coherent Light

Communication system of coherent light and direct detection light is similar in structure; it can be still divided into transmitting terminal, fiber channel and receiving terminal. Generally speaking, the effect of transmitting terminal (Tx) in light communication system includes source coding, bit to symbol mapping, modulation of optical carrier, certain pre-compensation etc. At present, large capacity and long distance transmission system uses external modulators, such as MZM. It is composed of 2 phase modulators and their modulation principles are based on optical interference. MZM is divided into SD and DD, of which, the driving voltage of upper and lower arm of SD-MZM is the same, SD-MZM operated in push-pull model can be used for AM and two order phases (0, tt), and SD-MZM operated in push-push model is equal to one phase modulator. Figure 1 shows the diagram optical transfer function and energy transfer function of SD-MZM. The abscissa is the upper and lower voltage difference. By setting different voltage bias and peak value, SD-MZM can realize

modulation of ASK and BPSK. Figure 2 shows MZ working under model of push-pull and push-push.



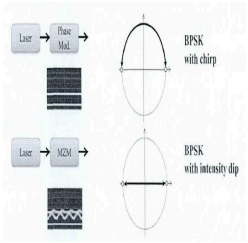


Figure 1 Transfer function of light field intensity and optical energy of SD MZM Figure 2 BPSK signal comparison of phase modulator and MZ modulator

The transfer function of SD-MZM amplitude is the nonlinear function of driving voltage, while most high-order modulation scheme is linear modulation scheme, that means the amplitude of signal I and Q component presents linear distribution relationship. The nonlinear of MZM modulation will result in signal distortion after modulation. In order to eliminate modulation nonlinear of MZM, the transmitter usually needs to make pre-distortion compensation for driving signal of MZM. Figure 3 shows the condition comparison of modulation depth of 16-QAM in signal constellation is respectively 1.0 and 0.3, that means the peal value of driving voltage of MZM is plant: 1.0 time and 0.3 time of T. From this we can see that whether pre-distortion or reduction in modulation depth can all eliminate or reduce nonlinear of MZM modulation, but we should notice that compensation of pre-distortion changes the phase trace among conversion of original symbol.

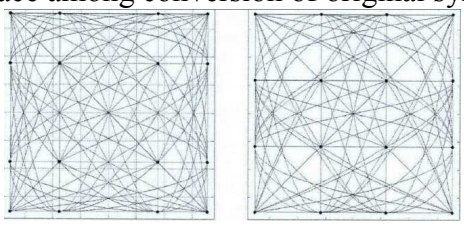

Figure 3 Effect of pre-distortion technology on signal modulation of 16-QAM

The most obvious difference between coherent detection and traditional direct detection lies in that the first one uses self-excitation or laser of phase locking as local oscillator to convert light frequency signal into base frequency or intermediate frequency. Secondly, the balance detector will convert the optical signal after conversion into electric signal; afterwards, analog-digital converter makes sampling for electric signal through certain oversampling ratio. Finally, the digital signal after sampling is transmitted to DSP system to make operations such as distortion compensation, judgment and coding etc.

Algorithm of Fiber Self-adaptation Dispersion Compensation

Self-adaptation dispersion compensation based on MMSE: Add dispersion estimation algorithm in front static dispersion compensation algorithm that means precisely and quickly as far as possible to estimate accumulated dispersion in the link then updates filter coefficients of static dispersion compensation wedge to make corresponding compensation. Because estimated self-adaptation dispersion compensation of MMSE is depend on training sequence. Firstly, its process calculates the dispersion effect of channel through known sequence, and then solves the MMSE answer of filter in time domain or frequency domain. Supposing that channel is dispersion channel and math module of signal is as follows:

$$u = h^T s + n$$
$$E[(s[k])^2] = 1$$
$$E[(n[k])^2] = N_0 \quad (1)$$

Of which, W is the received signal, S is vector of transmission signal, h is response vector of impulse channel, n is noise vector of additivity, the average power of signal is unit power, the power spectral density of noise is N0. The definition of its cost function is as follows:

$$J(w) = E[(e(k)^2] = E[(s(k) - w^T u)^2] \quad (2)$$

Of which, w is the estimated filter coefficient, according to the estimated definition of minimal MMSE, we can get the estimation quantity of W is as follows:

$$\overline{w} = \arg\min\{[(s(k) - w^T u)^2]\} \quad (3)$$

Through certain reduction and dilution, we can finally get representation of A is as follows:

$$\overline{w} = \frac{h^H}{h^H h + 1/\Gamma} \quad (4)$$

Of which, noise-signal ratio is r signal, h is the dispersion channel response calculated by training sequence. We can see that MMSE takes signal noise into consideration when estimating the best filter coefficient. After training sequence estimating impulse response of dispersion channel, it calculates the best filter coefficient, then updates TDE or FFT then updates FDE coefficient. The detailed realization scheme is indicated by figure 4.

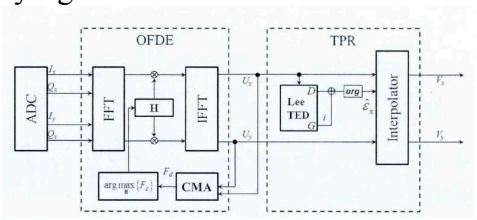

Figure 4 Self-dispersion compensation algorithm chart of OFDE and CMA deviation function

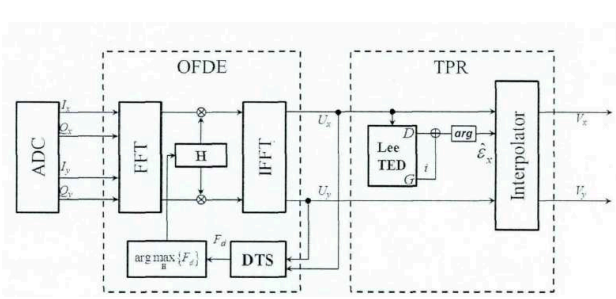
Self-adaptation dispersion compensation based on OFDE and time-delay sampling: Because field of fiber dispersion monitoring is sensitive to cost, time-delay technology generally adopts asynchronous sampling, its principle is very similar to the sampling oscilloscope of test equipment. At this time, supposing driving clock frequency of ADC is fs , the repetition frequency of signal is Rs, sampling interval is T=1/fs.

$$s_1(k) = s(kT + \tau_1)$$
$$s_2(k) = s(kT + \tau_2) \quad (5)$$

At this time, the sampling frequency is far smaller than symbol rate and they need to be integral and multiple relations, it is generally seen that the sampling time interval of ADC 1 and ADC 2 is set as half symbol period. The driving clock of ADC in coherent receiver is proximately 2 times of signal clock, therefore, the time-delay sampling used in coherent system is synchronous time-delay sampling, the relations of sampling rate and symbol rate is as follows:

$$f_s = 2R_s$$
$$\tau_1 - \tau_2 = 1/f_s \quad (6)$$

We can find that the time interval between 2 sampling points of each data is one stable value and it is depend on sampling frequency of ADC. At this time, the date of each polarization state can be understood as the coordinate of certain point in orthogonal coordinate system, the coordinate scheme composed of plenty of points like this is regarded as time-delay sampling scheme. The time-delay sampling scheme produced by X polarization data in zero QPSK system is indicated by figure 5. The self-adaptation dispersion compensation algorithm and principle based on time-delay sampling technology is indicated by figure 6.



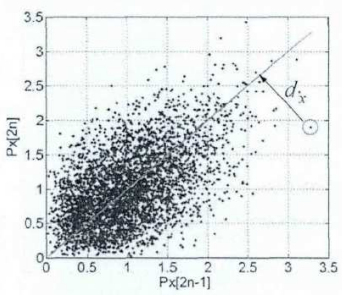


Figure 5 Principle scheme based on OFDE and time-delay sampling technology Figure 6 Time-delay sampling scheme produced by polarization data

If we define the distance from each point to diagonal as one variable d of time-delay sampling scheme, then we can get the following:

$$d_{x(y)} = \left| \frac{|s_{x(y)}[2n]|^2 - s_{x(y)}[2n+1]|^2}{\sqrt{2}} \right| \quad (7)$$

Choose one dispersion estimation parameter from it:

$$Fd=[std(dx)+ std(dy)]/2 \quad (8)$$

Of which, std means the standard difference of data. Dispersion estimated parameter is independently implemented in two polarization state and then eliminate the disadvantaged effect caused by polarization rotation.

Simulation Result and Performance Analysis

In the process of simulation, we use data length of Fd to uniformly set as 512. In addition, considering the feasibility of hardware, this length is respectively the integral time of different FFT length. Figure 7 shows simulation result of 2 kinds of self-adaptation dispersion estimation and compensation algorithm in PDM-NRZ-QPSK system. The simulation has totally carried out 81 independent tests. The sampling phase of receiver is randomly distributed between ±0.5. GCT method adopts GCT power as dispersion estimated parameter. DTS adopts the best matching improvement method of dispersion scanning. The result of precise scanning is subjected to sliding and filter processing of length 10 for one time. The range of precise scanning is rough estimated result ±200ps/nm. We can see that these methods can all get very precise dispersion estimated value in 2 systems. CMA and DTS algorithms have obvious performance degradation in QPSK system when OSNR less than 11db. The algorithm performance based on Lee TRP put forward by this paper is equal to GCT algorithm.

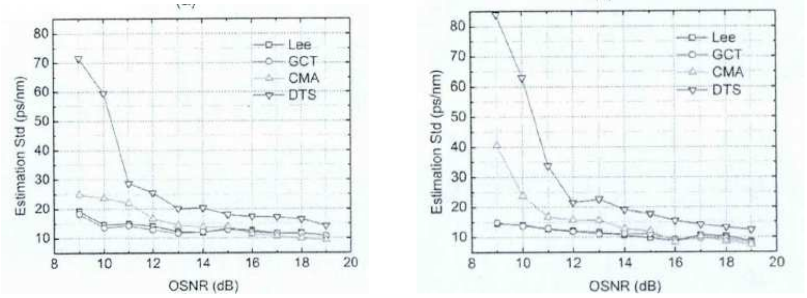

Figure 7 Relations between estimated performance of different self-adaptation dispersion estimation and compensation algorithm and SNRO.

Conclusion

Through theoretical analysis and system simulation, it further finds that these algorithms can be unified the best matching algorithm based on GCT. At the same time, the algorithm nature expression based on dispersion scanning and the best matching of GCT is also introduced in this chapter. The simulation result indicates that nature expression algorithm can get comparative or higher dispersion estimated precision on condition of using the same hardware resources. Through system simulation, this chapter gives the dispersion estimated performance comparison of different algorithms set under

comprehensive channel parameter; the simulation result further indicates that the algorithm performance base on the best matching of GCT and nature expression is the best.

Keywords: Attribute weight; Attribute importance; Mutual information; Rough sets theory; Information entropy

Abstract: There are various evaluation indicators in command information system. It is important to determine the weight of each indicator because it has a direct impact on the final result for evaluation and decision making. The reasonable and accurate attribute weight is helpful to ascertain the status or effect on the policy decision. With analyzing the deficiency of attribute weighting algorithms based on the rough sets theory, the new attribute weight algorithm is proposed in the paper. The proposed algorithm considers objective weight and subjective weight. The objective weight includes three factors, named as the importance of the attribute itself, the increment of mutual information, and its own information entropy. The subjective weight is obtained by the experts with prior knowledge in the field. Experiment results prove that the new method not only overcomes the deficiency of the existing weight methods, but also is more in line with the actual situation.

0 Introduction

The scientific and effective attribute weight is the most important for one system. At the present many scholars are dedicated to researching on it, and a lot of effective methods of assigning weight are produced. Article [1-5] proposed the objective weight method with the rough sets theory, the proposed algorithm only considered the effect of a single attribute on the decision results, and ignored the interactive influence between attributes, so some of the attribute weights with zero weight are necessary for the decision result are 0. Article [6] considers the overall importance of condition attributes, as well as the individual importance of each attribute, but the assigned weight isn't sometimes isn't line with the actual situation. With improving algorithm of article [6], in the paper the author puts forward one comprehensive attribute weighting algorithm, which consists of objective weight which is gotten by the rough sets theory and subjective weight that the experts give by a priori knowledge, such can make sure to realize the unity of the subjective and objective weight, and can improve the rationality of evaluation results. Experiment results also prove that the proposed algorithm is effective and rational.

1 The Basic Attribute Weight Principle Based on the Rough Sets Theory

Each attribute has different effect on the decision results for one information system. As usual we assign one attribute importance depending on the increment after removing an attribute. If the increment is more, we think the attribute importance is bigger. The attribute weight method based on the rough sets theory is mainly through the attribute importance of decision table. The follow is the correlative definitions.

Definition 1: $S=(U,A,V,f)$ is set as an information system. Among them, $U=\{U_1,U_2,\cdots,U_{[U]}\}$ is non empty finite set which is called the domain space, $A=\{a_1,a_2,\cdots,a_{[A]}\}$ is non empty finite attribute set, which is called the attribute set. $V=\cup A_a, a\in A, V_a$ is attribute's domain range, $f:U\times A\to V_a$ is the information function. When x is a , x has unique value in

V_a .On the other side, for sequence $C(c_1(x), c_2(x), \cdots, c_n(x))$ and sequence $D(d_1(x), d_2(x), \cdots, d_n(x))$, $A = C \cup D, C \cap D = \phi$, $S = (U, A, V, f)$ is called as decision table of the information system, $c_1(x), c_2(x), \cdots, c_n(x)$ is called as the condition attribute set.

Definition 2: For the given knowledge representation system $S = (U, A, V, f)$, the in-discernable relationship of any attribute is as follows:

$$IND(B) = \{(x, y) \in U \times U : \forall a \in B(f(x, a) = f(y, a)\} \quad (1)$$

Definition 3: For the decision table $S = (U, A, V, f)$, the degree that the condition attributes depend on the decision attribute is defined as follows:

$$\gamma_B(D) = |POS_B(D)| / |U| \quad (2)$$

Definition 4: For the decision table $S = (U, A, V, f)$, $c \in C$,the importance degree of condition attribute c is defined as:

$$SGF(c) = \gamma_B(D) - \gamma_{C-\{c\}}(D) \quad (3)$$

The weight of the condition attribute is defined as:

$$W(c) = \frac{SGF(c)}{\sum_{a \in C} SGF(a)} \quad (4)$$

According to the above formula we can see that the larger $SGF(a)$ is, the more important the attribute is, so the attribute weight is much greater.

2 Attribute Weight Based on Rough Sets Theory

The researchers utilize the relationship between knowledge and information entropy for rough sets theory, so the main concepts and operation of rough sets theory can be performed by the information theory.

Definition 5: U is set a domain , P and U is two equivalent relation of domain U (knowledge), $U / ind(P) = \{x_1, x_2, \cdots, x_n\}$, $U / ind(Q) = \{y_1, y_2, \cdots, y_n\}$, then the probability distribution that P and Q effect on the U is defined as follows:

$$[X : p] = \begin{bmatrix} x_1 & x_2 & \cdots & x_n \\ p(x_1) & p(x_2) & \cdots & p(x_n) \end{bmatrix}; [Y : p] = \begin{bmatrix} y_1 & y_2 & \cdots & y_m \\ p(y_1) & p(y_2) & \cdots & p(y_m) \end{bmatrix} \quad (5)$$

Among them, $p(x_i) = \frac{|x_i|}{U}, i = 1,2,\cdots,n; p(y_i) = \frac{|y_j|}{U}, j = 1,2,\cdots,m;$ the symbol $|E|$ is the base of E .

Definition 6: According to the information theory, the information entropy of knowledge P is $H(P) = -\sum_{i=1}^{n} p(x_i) \log p(x_i)$,the conditional entropy $H(Q|P)$ of the knowledge P relative to Q is :

$$H(Q|P) = -\sum_{i=1}^{n} p(x_i) \sum_{j=1}^{m} p(y_j|x_i) \log p(y_j|x_i) \quad (6)$$

The mutual information $I(P;Q)$ of the knowledge P relative to Q is:

$$I(P;Q) = H(Q) - H(Q|P); \quad (7)$$

Definition 7 [3] : The attribute importance is calculated by the increment of mutual information with subtracting one attribute, the definition is as follows:

$$SGF_{old}(c) = I(C;D) - I(\{C - c\}; D) = H(D|C - \{c\}) - H(D|C) \quad (8)$$

3 The Improved Attribute Weight Algorithm Based on Rough Sets Theory

Attribute importance in formula (8) only considers each attribute's effect on the whole decision, without considering attribute itself effect on the result of the decision. So the following results appear: the increment of the mutual information is more bigger, and the corresponding attribute weight is higher, so the attribute is considered as more important, but the actual situation is on the contrary, the attribute is maybe less important. So in the paper the author improves on the algorithm of article [6],and proposes one new importance algorithm with considering important degree of the

condition attribute itself, the increment of the mutual information, as well as information entropy of attribute itself on the decision results , the define is as follows:

$$SGF_{new}'(c)=(I(C-\{c\};D)-I(C;D)+I(c;D))/H(D|c)=(H(D|C)-H(D|C-\{c\})+H(D)-H(D|c))/H(D|c)$$

$$=(H(D|C)-H(D|C-\{c\})+H(D))/H(D|c)-1 \quad (9)$$

The weight is defined as: $W_k(c)=\frac{SGF_{new}'(c)}{\sum_{a\in C} SGF_{new}'(a)}$ （10）

From the above formula, we can see that the corresponding attribute importance is much greater when the mutual information increment is equal and $H(D|c)$ is smaller, attribute importance is much bigger.

In addition, in order to avoid the objective weight disaccord with the actual situation, in this paper the author assigns weight from two sides named as the subjective weight and objective weight, the subjective weight is determined directly by the expert's experience, the objective weight is obtained by formula (10), the comprehensive weight is defined as the following:

$$W_z(c)=\alpha W_s(c)+(1-\alpha)W_o(c) \quad （11）$$

Among them: α is called experience factor, which reflects the extent of the attribute importance, α is affected by the expert experience, the greater it is , the expert's subjective experience affects greatly the result of the decision, when $\alpha=1$, $W_z(c)$ is completely decided by the expert subjective weight

Table1 Decision table of information system

Samples	Wired communication capacity（bps）c_1	Wireless communication capacity （bps）c_2	voice quality c_3	transmission quality c_4	decision results d
1	1	1	1	1	1
2	1	1	2	2	2
3	1	1	3	1	3
4	1	1	3	3	3
5	1	4	1	3	4

7	2	2	1	2	2
8	2	3	1	2	3
9	2	4	2	1	4
10	3	3	1	1	3
11	3	4	3	2	4
12	4	2	2	1	4
13	4	2	3	3	4
14	4	3	3	1	4
15	4	4	2	3	4
16	1	3	2	3	4

4 Algorithm Analysis

In order to verify the effectiveness of the above algorithm, we use it into one command and information system, as shown in Table 1. From it, we can see that the system has 4 attributes, 16 experts give those evaluation results, the condition attributes are $\{c_1,c_2,c_3,c_4\}$, decision attributes are $\{d\}$, the value of set C is set as V={1,2,3,4}, The value of D is set as {1,2,3,4}, which corresponds excellent, good, general, poor state respectively. After pretreatment on the original data, we get the decision table shown in Table 1

The below is the processing in accordance with the algorithm of section 3:

We consider Table 1 as an information system, $U=\{x1,x2,x3,x4,x5,x6,x7,x8,x9,x10,x11,x12,x13,x14,x15,x16\}$, $IND(D)=\{\{x1\},\{x2,x7\},\{x3,x4,x6,x8x10\},\{x5,x9,,x11,x12,x13,x14,x15,x16\}$. The important degree of each attribute is calculated according to the formula (9), the objective weight are listed in table 2:

From table 2, we can see that the weight of attribute c_1,c_2,c_3,c_4 obtained by article [6] were 0.242569, 0.235703, 0.231209, 0.290517 respectively. But the weight of attribute is obtained according to the algorithm proposed in this paper is 0.336972, 0.34979, 0.313238, 0.389046 respectively. In addition, we invite the experts in the field of command and information system to assign the subjective weight for four attribute c_1,c_2,c_3,c_4 as (0.35, 0.35, 0.15, 0.15)respectively.

The experts set experience factor $\alpha = 0.4$ in considering of objective data, the comprehensive weight depending on the formula (11) is obtained as follows:

$W_z(c1) = 0.342183 \quad W_z(c2) = 0.349874 \quad W_z(c3) = 0.247943 \quad W_z(c4) = 0.293428$

In the actual command and information system, the quality of wireless communication capacity plays a decisive role on the operational effectiveness of the whole system because of wireless communication is a large proportion of communication in the current battlefield. From the experiment results we can see that the weight value of c_1 and c_2 is the two largest in the all attributes, the weight of c_3 and c_4 are the least in the all attributes, which is completely in line with the actual situation, so the experiment results verify that the proposed algorithm in this paper is rational and effective.

Table 2 The attribute object weight

attribute	$H(D)$	$H(D\|C)$	$H(D\|\{C-c\})$	$H(D\|c)$	$SGF_{old}(c)$	$W_{old}(c)$	$SGF'_{new}(c)$	$W_k(c)$
c_1	4.3923	0	0.2875	1.5558	1.2683	0.242569	1.638385	0.336972
c_2	4.3923	0	0.2875	1.5199	1.2324	0.235703	1.700704	0.34979
c_3	4.3923	0	0.3810	1.5899	1.2089	0.231209	1.522989	0.313238
c_4	4.3923	0	0	1.5190	1.5190	0.290517	1.891573	0.389046

5 Conclusion

In view of the deficiency of the attribute weight method based on the rough sets theory at present, the author proposes one new comprehensive attribute weight algorithm including the objective weight and subjective weight. The subjective weight can correct the deviation caused by the object weight. The objective weigh based on rough sets theory includes three factors, named as the importance of the attribute itself, the increment of mutual information, and its own information entropy change. Experiment results prove that the new proposed method completely avoids the weight 0, and it is more effective and reasonable than the existing algorithm.

Keywords: Task Oriented； Agent； Leaning and Evolution

Abstract. The leaning and evolutionary (L&E) algorithm of Agent for task oriented is deeply researched in this paper. Based on the relationship between tasks and the executive Agent, the importance of the research has been elaborated. Moreover, the algorithm is improved by considering the effect of environment and network structure. Reinforcement leaning and complex network have been introduced into the nonlinear genetic algorithm. Finally, some simulations of equipment acquisition tasks are made to test the validity and capability of the algorithm.

Introduction

Agent based modeling and simulation [1] is widely used to solve kinds of complex issues, such as space launch, equipment acquisition, etc. Leaning and evolution (L&E) is not only the foundation for Agent in “society” or “environment”, but also the main character of adaptability of Agent [2]. Task oriented has been the main solution to solve the problems. Besides, the evaluation of the effect of task completion is greatly decided by the executor. So how the executer learns and evolutes will affect the task completion is becoming more and more important point. Nowadays, most of the research about the L&V focuses on the Genetic Algorithms (GA) or improved GA [3,4]. However, the main defect of the algorithm of Agent L&V is that the consideration of the impact of the environment and network structure is not enough.

In this paper, nonlinear genetic algorithm (NGA) [5] is firstly introduced into the algorithm of Agent L&E. Its main part is that the factor of crossover and mutation probability was designed for adaptive changes according to the hormonal regulation of law, which reflects the adaptive characteristics of Agent. Besides, reinforcement learning [6] was concerned to reflect the effect of environment on Agent. Subsequently, the network structure [7] and the node state of Agent is studied.

The rest of the paper is organized in the following sequence. In section 2, the relationship between task and the executer is introduced in detail. In section 3, the algorithm of Agent leaning and evolutionary is redesigned. In section 4, some simulations of equipment acquisition are made to test the validity and capability of the algorithm. Concluding remarks are summarized in the final section.

The relationship between task and the executer

The relationship between task and the executer is illustrated in Fig. 1.

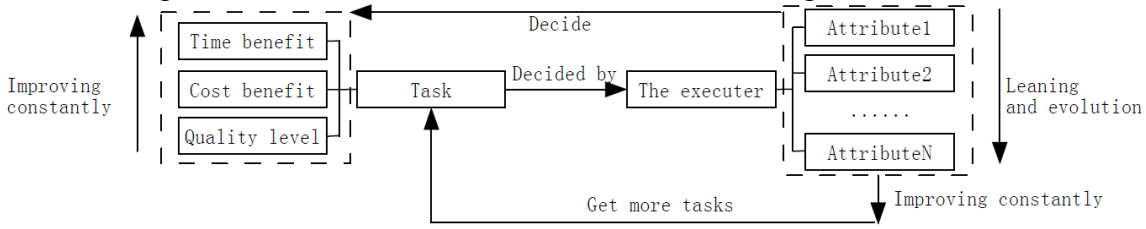

Fig.1 The relationship between task and the executer

1. In the competitive environment, the executer only by constantly improve the relevant properties of its own, to obtain the most objective task, also bring more revenue.

2. Attributes of the executer improved will improve the task completion effect as well.

3. The other executer will get changed, which have supply and cooperate relationship.

Therefore the process of the improvement of executers is abstracted as Agent L&E.

Redesign of the algorithm of Agent L&E

The solution of the redesign is shown in Fig.2.

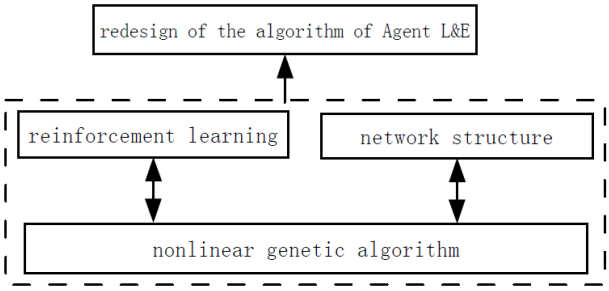

Fig.2 The solution of the redesign

In this section, the redesign is shown as follows:

1. Chromosome and the encoding mechanism

The attributes which mostly reflect the Agent and impact the task completion are selected as the chromosomes. According to the different types of parameters, a hybrid encoding mechanism of decimal and binary is recommended.

2. Fitness function

Fitness function is used to describe the performance of Agent in the environment and the adaptability. Fitness is adjusted according to the performance of Agent and change the corresponding individual fitness value, so as to provide a basis for genetic manipulation and evolution. Fitness function is redesigned from the following two aspects: □The number of tasks completed. Time, cost and quality evaluation of tasks completed. The form of the function can be expressed as follows:

$$fitness = \omega_1 * (1 - a^N) + \omega_2 * (1 - a^{e_time}) + \omega_3 * (1 - a^{e_cost}) + \omega_4 * (1 - a^{e_quality}) \quad (1)$$

where $\omega_1, \omega_2, \omega_3$ and ω_4 represent the weight of each item. The parameter a is the normalized parameters ($0 < a < 1$). N denotes the number of tasks completed. Besides, the symbol 'e_time' is the time evaluation, which can be obtained through the calculation between the actual completed time and the expected time. Similarly, the parameter e_cost can be obtained. And the $e_quality$ is from specify quality evaluation index system.

3. Optimized design of genetic operator

(1)Selection and crossover operator

If the population is fewer, a shock will appear in evolution direction when the individual having largest fitness is not selected. To avoid this situation, two strategies are put forward as follows:

□The best individual should be reserved forcibly, which will bring monotone increasing to the largest fitness.

□When the individual is sorted by fitness, the ones having smaller fitness will be removed in proportion. Subsequently, the individuals having larger fitness will be selected to reproduce cross.

The crossover probability is from the nonlinear genetic algorithm.

$$P_c = P_c^0 (1 + \alpha \frac{(f_{av})^{nc}}{(f_{\max} - f_{\min})^{nc} + (f_{av})^{nc}}) \quad (2)$$

where P_c and P_c^0 denote the crossover probability and initial crossover probability, respectively. The parameters f_{av}, $f_{\max}$, $f_{\min}$ represent the average, the maximum and the minimum fitness of the population. Moreover, α and nc are the coefficient factor, α controls the slope of Hill function.

To the decimal coding parameters, linear cross method is used. The form is as follows:

$$P_{child} = r * P_{parent1} + (1 - r) * P_{parent2} \quad (3)$$

r for a random variable obeying the uniform distribution at the range of $[0,1]$.

To the binary code parameters, two factors of cross location and cross amplitude are used to descript. The cross location is randomly generated. And cross amplitude is the absolute value of difference of individual parameters.

When the crossover operation is carried out, the network structure between Agents should be taken into consideration. In the following step, three principles are proposed.

①Prior to learn from the one with a biggest difference between out-degree and in-degree.

②Prior to learn from the one with the last state was not involved in the crossover operation.

③Prior to learn from the one with the biggest betweenness.

An Agent is one node of the network, so two state variables are added: degree and SIR state [8].

(2) Mutation operator

The mutation probability is from the nonlinear genetic algorithm.

$$P_m = P_m^0(1+\beta\frac{(f_{av})^{nm}}{(f_{\max}-f_{\min})^{nm}+(f_{av})^{nm}}) \tag{4}$$

where P_m and P_m^0 are the mutation probability and initial mutation probability, respectively. Parameter β and nm are the coefficient factor and β controls the slope of Hill function.

To the decimal coding parameters, the form of the mutation amplitude is defined as follows:

$$\Delta P_i = \frac{i}{fitness_i} \tag{5}$$

To the binary code parameters, two factors of mutation location and mutation amplitude are used to descript. The mutation location is randomly generated. And the mutation amplitude is inversely proportional to its fitness. The form is as follows:

$$\Delta P_i = \left[\frac{i}{fitness_i} * M\right] \tag{6}$$

M is the length of the binary code parameter.

Simulation and analysis

In the following step, some simulations of equipment acquisition tasks are made to test the validity and capability of the redesigned algorithm. In the agent based modeling and simulation of equipment acquisition, there are two main types of Agent [9]. They are the agency of equipment acquisition and the defense industry enterprise.

Here, the enterprises are selected to be the executers. The attributes of the enterprises and the coding modes are shown in table 1.

Table 1 Attributes of the enterprises and coding modes

	Attribute	Coding mode		Attribute	Coding mode		Attribute	Coding mode
1	Innovation_ability	binary	3	Quality_level	decimal	5	Credit	decimal
2	Manage_level	decimal	4	Cost_control	decimal			

The initialized values of the attributes are from questionnaires and history data.

The initialized parameters of the redesigned algorithm are shown in table 2.

Table 2 Initialized parameters of the redesigned algorithm

	Parameter	Initialized value		Parameter	Initialized value		Parameter	Initialized value
1	ω_1	0.7	5	P_c^0	0.1	9	nc	2
2	ω_2	0.1	6	P_m^0	0.7	10	nm	2
3	ω_3	0.1	7	α	0.2			
4	ω_4	0.1	8	β	0.1			

If $P_c^0 = P_m^0 = 0$, that is no algorithm used in the simulation.

The whole simulation was designed and implemented on Recursive Porous Agent Simulation Toolkit (Repast) [10].The usage of the algorithm of Agent L&E is shown in Fig. 3.

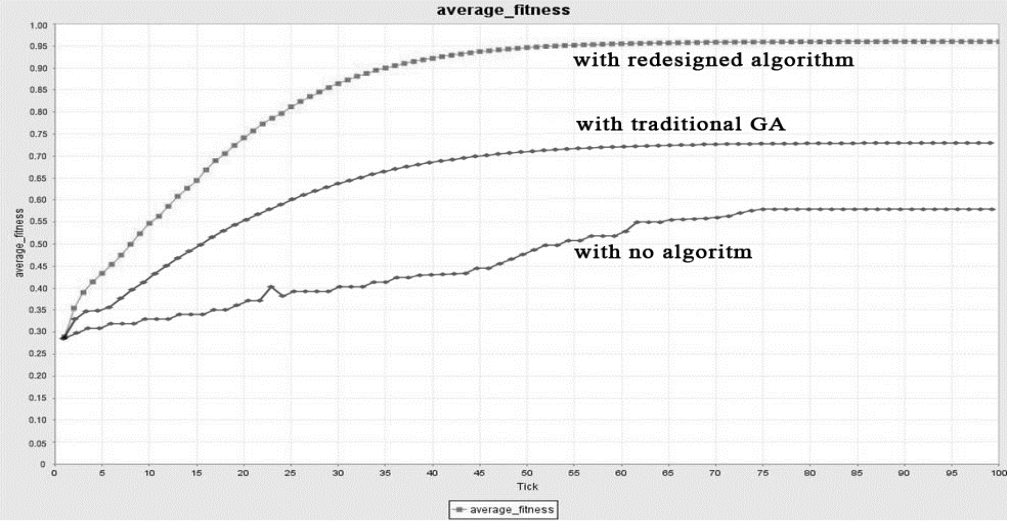

Fig. 3. The usage of the algorithm of Agent L&E

As we can see from Fig. 3, through the contrast curves, due to considering the environment and network structure, the average value of the individuals can quickly reaching a higher maximum by using the redesigned algorithm. Meanwhile, it reflects the overall trend of the equipment acquisition task completion. Under the guide of military, the comprehensive evaluation of time, const and quality of task completion is becoming higher and higher.

Conclusion

In this paper, an algorithm of Agent L&E based on nonlinear genetic algorithm, reinforcement learning and network structure is redesigned. The simulation of equipment acquisition task shows the validity and capability of the redesigned algorithm. With more and more Agent based modeling and simulations, task oriented is becoming the main solution to the issues. The thoughts and methods redesigning the algorithm of Agent L&E will get wider and wider application to solve social problems, such as space launch, economic market, logistics management etc.

Keywords: Major depressive disorder; human brain functional network; modeling; the proportion of the common edges of two networks

Abstract: In order to analyze the gap of function network between Major depressive disorder and health person, this paper studies with modeling approach. This paper analyzes the function network of Major depressive disorder with the model based on anatomical distance and the number of common neighbor. The result shows that the distribution of the optimal brain function network is linear in all volunteer. And the slope of the linear relationship in the patients is less than health, so we hope this point can be as secondary evidence to determine the person whether fall ill. And we also propose two models and those models of brain function are based on anatomical distance or the number of common neighbor. Create the evaluation criteria for select the optimal brain function model network in each class model based on select the maximum value in the proportion of the common edges of two network accounted all edges. Select the model that can simulate the real brain function network by comparison with real data fMRI network. Finally, the results show the best model only is based on anatomical distance .

0 Introduction

Major depressive disorder (MDD) is a frequent heart disorders. Although in recent years, treatment of MDD has been greatly improved, but the relapse rate of MDD was still very high. Functional imaging studies have shown that MDD related to the abnormalities of many areas of the brain.[1-2] These areas include Hippocampus, ParaHippocampal, Precentral, Caudate and so on.

The human brain network is a large and complex network, in the sense of having high metabolic cost relative to its mass.[3] Similarly, the computer network is a typical economy small world network. Its economic characteristics are mainly reflected in the minimization of brain anatomy distance or connection costs.[4] Prior studies indicate that those topological properties of brain network is affected by anatomy distance and cost control. Meunier analyze the modular of resting-state brain function network of healthy volunteers. It was found that the anatomy distances between nodes in the same module are shorter than others.[5] The long distance connection in the same module distributed in the opposite side homotopy area of the node. Studies indicate that the brain region that have more connection in local area have some properties such as clustering coefficient is higher , characteristic path length is longer and connection costs is lower.[6]

On one side modeling of brain function network based on anatomy distance found the relationship between anatomy distance and cost control and topological properties of brain network. On the other hand it is important to reduce the cost of building brain network. Kaiser makes anatomical distance between nodes as the only parameter of the modeling of brain network about cat and rhesus monkey.[7] It found that the anatomical distance between regions which have shorter characteristic path length are shorter normally. Previous study had analyze the gap of function network between MDD and health person in many other way, this paper studies with modeling approach. And propose three models of brain function network with the data of health person in order to analyze the effects that anatomical distance and the number of common neighbor between nodes to brain function network. The three models have two parameters --- anatomical distance between nodes (Euclidean distance between two nodes) and topological properties (the number of common neighbor between nodes). In this article , those models imitate some key topological properties of healthy volunteers' brain function network. In the model based on two parameters, experiments show we can determine the person whether fall ill by the ratio between two parameters.

In other word, the ratio between two parameters of the optimal model have significant different between MDD and health person.

1 Collection and processing of data

1.1 Collection and pre-processing of data

In this study collect 60 subjects and they divided into two groups: MDD group and control group .MDD group including 34 MDD volunteers (evaluable data on n=34; mean age 29; 14 male). They are first onset without medication, and they ranged in age from 17 years to 54 years. Control group including 26 healthy volunteers (evaluable data on n=26 ; mean age 27; 11 male). They ranged in age from 17 years to 63 years. All subjects of Control group had no history of mental or nervous disorders according to Mental Health Screening Table and Neurosis Screening Schedule. All subjects of MDD group are patients with MDD according to diagnosed and statistical manual of mental disorders in united states with fourth edition (DSM-IV).

This study consent was acquired from all participants and signed a written agreement with them.

Collection and pre-processing of data was complete by First Hospital of Shanxi Medical University and us. The experiment using resting-state fMRI (functional magnetic resonance imaging) collect image data. Then research the pattern of resting-state brain functional connectivity. Collection of data was complete in First Hospital of Shanxi Medical University. Scanning was complete by radiologist who qualified in operation of magnetic resonance. During the process of scanning, the subjects were asked to close their eyes, relax, not think about certain things and stay awake.

In order to preprocess the data, experiment use Statistical Parametric Mapping 8(SPM8) which belongs to software Matlab7.8.The process include: time between layers correct; head motion correct; spatial normalization; make multiple linear regression on all time series; remove the false difference caused by head motion.

1.2 Construct brain function network based on time series

In order to construct brain function network based on time series, experiment do steps as following. First, brain was divided into 90 cortical brain regions (each hemisphere have 45 cortical brain regions) according to Anatomical automatic labeling (AAL) templates. Each region is treated as one Regions of Interest (ROI). Each region stand for one node in brain function network, so the number of node in brain function network is 90. Calculate the average time series of all voxels in each region. Then analysis the result with multiple linear regression in order to remove the pseudo differences caused by head movement and global brain signals. Then calculate the pearson correlation coefficient between any two cortical brain regions.

$$r_{ij} = \frac{\sum_{t=1}^{T}[x_i(t)-\bar{x}_i]\bullet[x_j(t)-\bar{x}_j]}{\sqrt{\sum_{t=1}^{T}[x_i(t)-\bar{x}_i]^2}\sqrt{\sum_{t=1}^{T}[x_j(t)-\bar{x}_j]^2}} \quad . \tag{1}$$

Here, X_i is time series of voxel i ; X_j is time series of voxel j; X_i with over line is the average of the time series of voxel i ; X_j with over line is the average of the time series of voxel j. So we get the relational matrix A (90×90) that is about time series. Turn relational matrix into binary matrix according to the pre-set threshold value. In other words, when $r_{i,j}$ larger than the threshold value , the corresponding element of the binary matrix is 1. when $r_{i,j}$ less than the threshold value , the corresponding element of the binary matrix is 0.

Select threshold value. In order to turn relational matrix into binary matrix ,we need to select threshold value for each relational matrix. Each threshold corresponds to a sparsity. Sparsity defined as the ratio of the number of edges that is actually exists in brain network and the number of edges that maximum possible exists in brain network. The selection that we make is a threshold range. Construct brain function network (relational matrix) in each sparsity within the space of threshold. Determine the space of threshold on the following principles:

(1) For all subject, the small-world properties of all brain function network within the space of threshold must be larger than 1.1.
(2) For all subject, the average degree (K) of all brain function network within the space of threshold must be larger than

$2\ln N \approx 9$. Here, $N = 90$。

According to this principle, we select a threshold space that is 8% -32%. Increasing sparsity step by step within the space of threshold, and the gap was 0.1 per step. Construct brain function network for all subject in each sparsity. Finally, calculate the mean brain function network of a group subject within each sparsity.

1.3 Calculate topological properties of brain function network

For each brain function, we measured the topological properties as following: Characteristic path length (The extent of overall routing efficiency of a network. In other word, it is the shortest path length required to link one node to another, averaged overall all pairs of nodes.); Clustering coefficient (The extent of local clustering or cliquishness of a network. In other word, it is the average of the clustering coefficients over all nodes and quantifies the local interconnectivity of a network.); Global efficiency (How efficient of information propagation through the whole network); Local efficiency (How efficient of information propagation over a node's direct neighbors); Assortativity (The tendency of nodes to link those nodes with similar number of edges).

2. The evaluation criteria of optimal brain functional model network

In order to select the optimal human brain function model network of each class human brain function model networks. Experiment selects the best parameter group in each class human brain function model networks and the model network that construct according to the best group parameters closest to the real brain function network that construct according to time series. Here, we select the optimal model network by analyze the percentage of the common side of the two networks.

Firstly, calculated the S value of percentage of the common side between each model network and the real network in a sparsity.

Finally, we sort all S value in the sparsity. Select the brain function model network which S value is the largest and it is the optimal human brain function model network in this sparsity.

3.Model of human brain function network

3.1 Model of human brain function network based on anatomical distance (MAD)

One measure of cost in a spatially embedded network like the brain is the physical distance of connections between nodes: generally, connection costs will increase with distance. In the nervous system of the nematode worm Caenorhabditis elegans, which has been mapped completely at the cellular level of synaptic connections between neurons , most axonal projections are shorter than the average distance between neurons, as expected in response to an economical selection pressure .[8-10] Likewise, in sparsely connected human brain functional networks, short distance connections predominate and are typically associated with greater strength of functional connectivity between regional nodes. In order to investigate the effects of anatomical distance to human brain function network, we design a model: This model consists of $P_{i,j}$ which are the connection between any pair of nodes and $P_{i,j}$ is a function of the anatomical distance between any pair of nodes:

$$P_{i,j} \propto (d_{i,j})^{-\eta} . \tag{2}$$

Here, $d_{i,j}$ is the anatomical distance between node i and node j, η is the only parameter of the model.

3.2 Model of human brain function network based on the number of common neighbor (MNCN)

Growth models for the formation of other real-life complex systems have previously been more successful by including an additional topological term in the connection probability function . Human brain functional networks are embedded in anatomical space and have topological

properties—small-worldness, modularity, fat-tailed degree distributions—that are comparable to many other complex networks. We mainly investigate the effects of number of common neighbor between nodes to human brain function network. More the number of common neighbors between any pair nodes, more similarity between the nodes (Brain regions). We design a model: this model consists of $P_{i,j}$ which are the connection between any pair of nodes and $P_{i,j}$ is a function of the number of common neighbor between nodes:

$$P_{i,j} \propto (k_{i,j})^{\gamma} \quad . \tag{3}$$

Here, $k_{i,j}$ is the number of common neighbor between node i and node j, γ is the only parameter of the model.

3.3 Model of human brain function network based on anatomical distance and the number of common neighbor (MADNCN)

With the above experiments, we analyzed the effects of only anatomical distance or only number of common neighbor between nodes to human brain function network. What result when construct brain function model network based on both anatomical distance and the number of common neighbor between nodes. Whether the brain function model network will be more close to the real human brain function networks? We design a model: this model taking into account anatomical distance and common neighbor between nodes. In other word, this model consists of $P_{i,j}$ which are the connection between any pair of nodes and $P_{i,j}$ is a function of anatomical distance between nodes and the number of common neighbor between nodes:

$$P_{i,j} \propto (k_{i,j})^{\gamma} (d_{i,j})^{-\eta} \tag{4}$$

Here, $d_{i,j}$ is the anatomical distance between node i and node j; $k_{i,j}$ is the number of common neighbor between node i and node j; η,γare the parameters of the model.

In the above three models, the parameters η, γ are the range (0,7] and they changes in steps of 0.1. Firstly, construct a lot of human brain function model network through changing parameters constantly in each class model. Secondly, select the optimal human brain function model network of each class human brain function model networks by the evaluation criteria of optimal brain functional model network. Notice, the optimal human brain function model network in the class model that based on both anatomical distance and common neighbor between nodes is not the only. But, analysis the optimal human brain function model network under the same sparsity , we find that the connection of these optimal model network are same exactly although the parameters of these optimal model network are different. So we recognized those optimal models that based on both anatomical distance and common neighbor between nodes under the same sparsity as one network. Calculate the five kind topological properties of each brain function network in each sparsity within threshold space that is 8% -32% in each class model. The five kind global properties are: characteristic path length, clustering coefficient, global efficiency, local efficiency, assortativity.

4. Results and analysis

Analyze the optimal model network based on anatomical distance and the number of common neighbor of both MDD and health person, we found that the S value of percentage of the common side between optimal model network and the real network increase when the sparsity increase in all object and the increasing trend is linear. (Fig 1)

In addition, create an axis and X-axis represents the parameter γ, Y axis represents the parameter η.when the model network based on anatomical distance and the number of common neighbor ,no matter the data is MDD or health person, we select all optimal model network in a sparsity and these models are placed in the appropriate location in axis. The experimental results show that the distribution of the optimal brain function network is linear in all volunteer. We also find that the slope of linear relationship of two parameters of the optimal brain function network in

control group is greater than the slope of MDD group. Calculate the averages of all slope of linear relationship of two parameters of the optimal brain function network in control group with all sparsity within threshold space that is 8% -32% and the value is 0.9536. And the value of MDD group is 0.8852. So we can modeling the unknown object, select their optimal brain function network and get the slope of linear relationship of two parameters. If the value close to 0.9536 ,the object is health peoson. If the value close to 0.8852 ,the object is MDD.

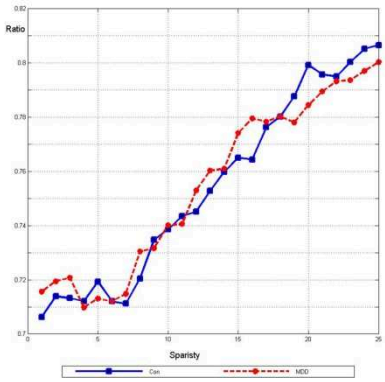

Fig 1 Increasing trend of S value

With the data of control group, calculate AUC value of each topological properties of each network in every sparsity within threshold space that is 8% -32%. Compare the AUC value of each kind topological properties of real human brain function network and five kind topological properties of the optimal model network in each class model. The result show that the human brain function model network only based on anatomical distance is closest to the real resting-state brain function network. (Fig 2)

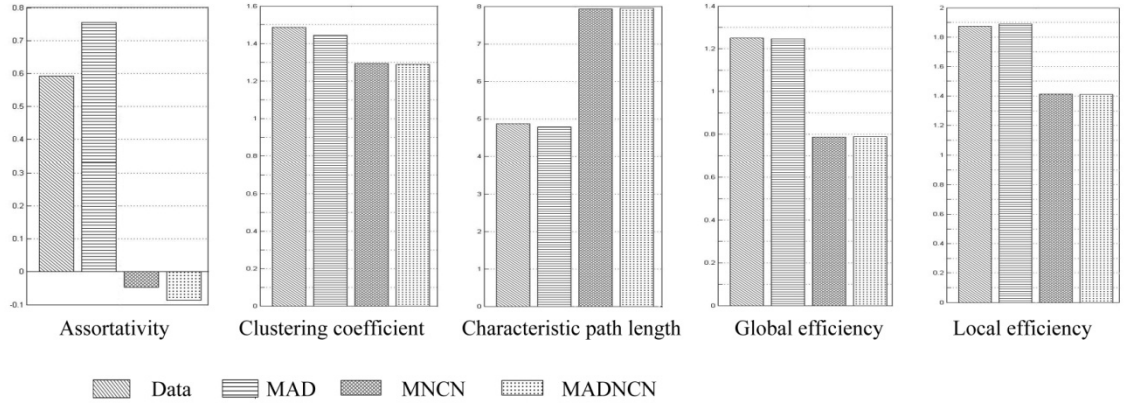

Fig 2 Compare the five kind topological properties of real network and three model

The above experiments show that if the optimal human brain function model network only based on common neighbor between nodes, their characteristic path length will longer, and the efficiency of information transmission in network will lower. In other word, the model network is not a highly efficient network. The optimal human brain function model network based on both anatomical distance and the number of common neighbor between nodes is affected by number of common neighbor between nodes severely. So this kind of model network can not reflect the characteristics of the real human brain function network. The human brain function model network only based on anatomical distance can simulate the real human brain function network in the high degree of accuracy. Their global efficiency and local efficiency are very close to the real human brain function network. This is fit with the experience that brain function network is a highly efficient network in the process of information transmission. Notice, their characteristic path length is very close to the characteristic path length of real brain function network. In other word, their characteristic path length is lower compare with another two kind model network. And it show that short distance connections predominate in human brain function network. At the same time, the

other topological properties —such as clustering coefficient and assortativity — of the human brain function model network only based on anatomical distance also closet to the real human brain function network. When we select a definite template, the anatomical distance between any two nodes is fixed. In other work, the anatomical distance between any two nodes is same to all volunteer and it is common feature. The real human brain function network is mean network in experiment, so the effect of individualized feature is not reflect in result and the effect of common feature is very prominent. And it cause the human brain function model network only based on anatomical distance closet to the real human brain function network in the result directly.

5. Concluding remarks

In this paper, the experiment has proved that the model based on anatomical distance and the number of common neighbor have significant different between MDD and health person. In addition, the model only based on anatomical distance closet to the real brain networks. Future studies can be further analyzed the different between MDD and health person in the field of modeling. We also can analyzed other factor in order to find the model which is closet to real brain function network. In future studies could investigate how to improve the efficiency of the modeling in order to save time and complexity of calculate.

Abstract

Classification of moving military vehicle in battlefield is an important part of information acquirement. Support vector machine is a pattern classification method which is suitable to solve the small sample, non-linear classification problems. This paper uses one-versus-one multi-class SVM to classify military vehicle. This method is based on multi-sensor data including noise signal, the magnetic field disturbance signal, and vibration signal. The parameters of the SVM are determined by using the cross-validation method. The Simulation experiment results show that, compared to AdaBoost algorithm and two-class SVM, the one-versus-one multi-class SVM has higher accuracy.

Introduction

Military vehicles play an important role of modern warfare. The classification of moving military vehicle has become an interesting research field for battlefield intelligence information acquisition. Currently, there are few researches for military vehicle classification. The classification problem of military vehicle is similar to that of traffic vehicle. So classification method of traffic vehicle can be used for reference.

The machine learning algorithms for multi-class classification of moving vehicle include BP neural network classification algorithm[1], AdaBoost algorithm[2], and SVM classification algorithm[3]. HU used three-layer BP neural network for classification of three types of traffic vehicles[4]. Wang employed wavelet multi-scale edge detection and BP neural network to extract image features to classify the vehicle[5]. Chang describes a multi-class classification method based on cascade AdaBoost classifier. The above methods have achieved good results, but there are some problems: (1)BP neural network classification algorithm has some drawbacks such as high computation complexity, overfitting, and local optimum.(2) AdaBoost algorithm has a good real-time performance and high accuracy, however, it may appear data imbalance problem[6] and has long training time when training sample is large. The SVMs have become popular classification approach because of their small samples learning capability.

In solving multi-classification problems, binary-class SVM has larger error than multi-class SVM. Therefore, we deal with military vehicle classification problems based on multi-class SVM. In this work, the sound signal, vibration signal, and magnetic signal of military vehicles are treated as input samples of the classifier, and the multi-class SVM is introduced to achieve the vehicle classification. In addition, The parameters of the multi-class SVM are selected by using cross-validation method. The experimental results show that multi-class SVM has higher accuracy and faster convergence speed than Adaboost algorithm for the military vehicle classification problems.

Multi-class support vector machines

SVM classification algorithm was originally designed for binary classification problems. It has good effects for binary classification problems of small samples. However, for multi-class classification problem, a suitable multi-class classifier is needed. Currently, there are two main ways to solve the multi-classification problems of SVM. One is the direct method: by merging multiple parameters of hyperplane into an optimization problem, the optimization problem is solved to achieve

multi-classification. Such a method is only applicable to the classification problem of small samples. It has high computational complexity, low efficiency and low classification accuracy for the classification problems of large samples. The other is the indirect method: combining multiple binary-class classifiers to construct a multi-classification classifier. This method includes the following two: (1) one-versus-rest[7], in which N binary-class classifiers are built for a N-classification problem. For instance, when training the ith classifier, the ith sample in the training sample set belong to class 1,the rest samples belong to class 2.The classification result is determined by the largest output value of N classifiers.(2)one-versus-one[8], in which a binary-class classifier is built for each two classes. So, there are totally N(N-1)/2 SVMs. The results depend on these SVMs ’ voting. The research shows that one-versus-rest may cause some samples can’ t be classified, and has longer training time than one-versus-one. Therefore, this paper uses one-versus-one method to build multi-class SVM.

Classification method of military vehicles

In this paper, we study multi-classification method for three different types of military vehicles including tanks, armored vehicles, and trucks.

Feature extraction. The feature selection of input samples for SVM is very important. Nowadays, the information of military vehicles is primarily collected by various sensors. in general, military vehicles have their different characteristics, such as sound, magnetic field, vibration, etc. So considering with the actual situation of vehicle detection, we extracted three kinds of military vehicles’ characteristics as input feature vector of military vehicles classification. They are sound decibel, magnetic field induction, vibration intensity. The reasons are as follows: (1) These three characteristics are more easily perceived by sensors; (2) The characteristic differences among these three types of vehicles are obvious; (3) These three characteristics are hardly affected by weather conditions during day and night[9].

1) ? Sound feature

Vehicle noise is generated while the vehicle during moving.The level of vehicle noise has a direct and significant relationship with vehicle type. Sound characteristic value is represented by the noise power of vehicle.Thus the sound value is not be affected by distance between detection point and the vehicle.The noisy power P and distance of sound sensor r have the following relationship:

$$P = 4\pi r^2 I_0 * 10^{\frac{L}{10}} \tag{1}$$

Sound intensity level L is the decibel value which can be detected and exported by the sound sensor. I_0 is the reference sound intensity, and its value is $10^{-12}\,\mathrm{w/m^2}$.

2) Magnetic field feature

Geomagnetic field can be regarded as uniform distribution within a few kilometers. Due to vehicle’s magnetic field properties, when a vehicle passes through the geomagnetic field it will disturb the magnetic fields environment.

Large vehicle having higher metal content, thus its effect on the magnetic field surrounding is obvious. So the amplitude of the waveform has large range and is easy to detect. This characteristic provides a theoretical basis for vehicle classification based on magnetic field sensors. So magnetic field feature can be used as an input variable of military vehicle classification.

3) Vibration feature

The road which military vehicles run on can be regarded as a vibration system. Impact force of vehicle load can be used as an input of road vibration system. Because impact force road surface will produce a corresponding vibration response, the size of road surface vibration and the size of road load have the same trend and magnitude order. Road surface vibration increases with vehicle weight. Therefore, the shock wave of road surface can be detected to identify the corresponding vehicle type. After obtaining the vibration wave, the peak of amplitude can be extract as an input feature vector of vehicle classifier.

Classification algorithm of Military vehicle. Based on the above analysis, we adopt multi-class SVM and one-versus-one method for military vehicle classification. The input of SVM classifier includes three types of vehicle's feature value such as sound, magnetic field, vibration. FIG.1 shows the structure of SVM :

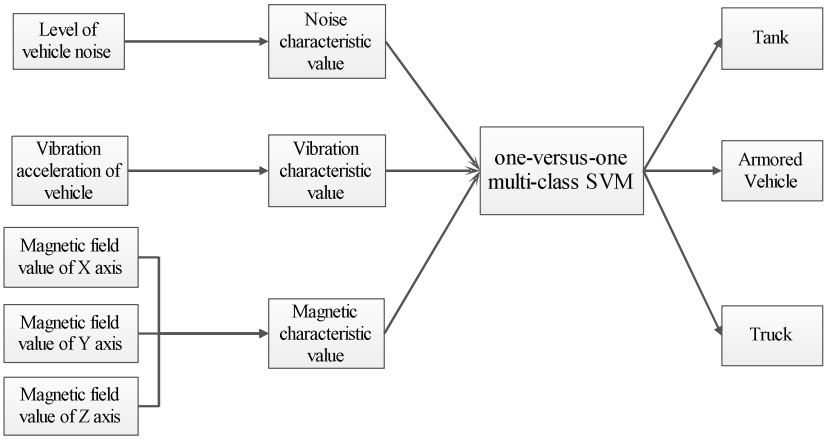

FIG.1 The structure of SVM

Simulation Results and Discussion

Simulation experiment platform. In this paper, the effectiveness of the classification algorithm for military vehicle must be evaluated by experiment. The experiment is based on Military Vehicle and Sensor Network Simulation Platform(MVSNS) which is developed by Intelligent Transportation and Data Fusion Laboratory, Department of Automation, USTC. This simulation platform can build different types of vehicle model and road model. It also can create spread diffusion models of sound, magnetic field and vibration of military vehicle.

The kernel function of SVM has a significant impact on classification result. Parameter C determines the optimal classification hyperplane and classification error. Parameter selection of SVM directly affects the accuracy of classification of military vehicles. In this paper, Gaussian kernel function is used to ensure the best classification result.

In addition, parameter $\sigma 2$ affect the performance of Gaussian kernel. We initially suppose the optimal parameters $\sigma 2 = 0.5$ and $C = 5$, and then use cross-iteration method for the precise search of optimal parameters. Finally, the optimal parameters are obtained, which are $\sigma 2=0.6$ and $C =5$. Two parameters achieve a better balance by using this search optimization method.

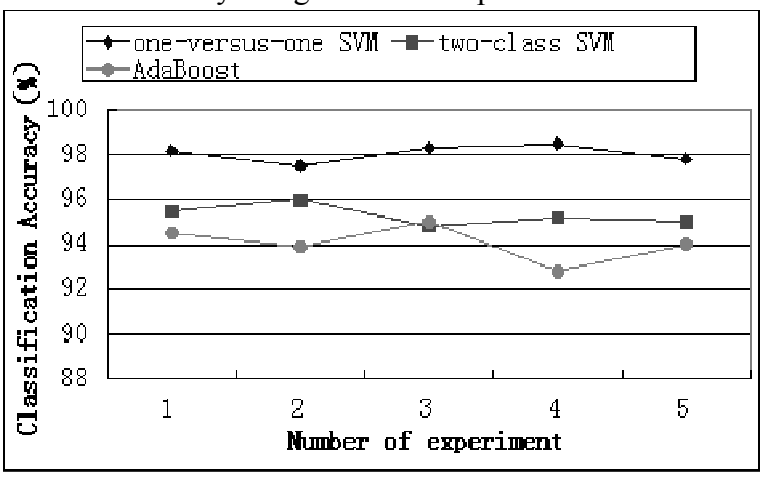

FIG.2 Comparison of their classification accuracy

The experimental results. In order to verify the effectiveness of the classification algorithm for military vehicle, MVSNS was used for classification experiment. In the experiment, the proposed method was implemented and compared with AdaBoost algorithm and standard SVM. AdaBoost algorithm is an iterative algorithm. Its core idea is to build a series of weak classifiers on the same

training sample sets, and then combines these weak classifiers together to construct a stronger final classifier.

In this experiment, the samples are generated by the MVSNS. The Simulation Platform generated 200 military vehicles for three types. The feature values of each vehicle were detected and output by virtual sensors in MVSNS. The classifier used the 600 samples and the experiment results are shown as Fig.2. It can be seen that the one-versus-one SVM classification method has higher classification accuracy than AdaBoost classification method and two-class SVM classification method. The classification accuracy of these three methods is as follows: one-versus-one SVM 98.06%; two-class SVM 95.3%; AdaBoost 94.68%. Therefore, one-versus-one SVM is suitable for military vehicle classification.

Conclusion

In this paper, a classification method of military vehicle classification is studied. The moving military vehicles' characteristics such as sound decibel, magnetic field induction, and vibration intensity are analyzed, which are treated as input feature vectors of one-versus-one multi-class SVM to generate a military vehicle classifier. This algorithm is evaluated on the simulation platform. The experimental results show that one-versus-one multi-class SVM has higher accuracy than AdaBoost and two-class SVM.

Keywords: Clustering Analysis, FFCM, Data Mining

Abstract. Data mining is the general methodology for retrieving useful information from big data. Clustering analysis is a mathematical method of classification for unsupervised machine learning. It can be adopted for data classification in Data mining. This paper combines the clustering process by fuzzy way and then deduces a special clustering algorithm with fast fuzzy c-means (FFCM) method. In summary, the paper illustrates the adoption of a series of fuzzy clustering methods in Data Mining. These methods have improved the computational efficiency with learning as the convergence speed is fast. The methodology of this paper presents significantly meaningful for information retrieval of big data.

Introduction

Over the last decade, people use information technology the ability to produce and to collect data greatly improved. Millions of databases are adopted for business management, government offices, scientific research and engineering development and so on. For making the data truly become a company's resources, the company's own business decisions and strategy development service must be taken full advantage of. Otherwise, big data might become a burden, and even might become garbage. Therefore, data mining and knowledge discovery technologies emerged and flourished, increasingly shown its strong vitality.

Clustering analysis is an important mining method of data mining. That means it calculates similarities among the data from the database, and the data classification of this method is conducted according to the similarities. Furthermore, the data from different classes are as possible as different and the data in the same class are as possible as similar; that means “similar objects are flock together”. Accordingly, it allows the useful information or knowledge implicit in the data to be searched and found by optimizing the large-scale database. Clustering analysis is a mathematical method to study and process a given object classification. Clustering has been widely used as a basic data mining method, such as, similarity search, customer division, pattern recognition, trend analysis and other fields. All clustering methods have their own characteristics. In data mining, clustering algorithms used are the following:

(1) Based on clustering division: first creating k divisions, k represents the number of divisions to be created; then using a loop positioning technology by moving an object from one division to another division to improve the quality of divisions.

(2) Based on hierarchical clustering: creating a hierarchy to decompose a given data set. This method can be divided into top-down (decomposition) and bottom-up (merge) two modes of operations. During the clustering operation based on hierarchical clustering method, it would assume that the data are a one-time offer, that is, it is a non-incremental algorithm, in which, the time complexities of a single connection, all connections and average connection and space technology complexity are O (n^2).

(3) The density-based clustering: according to the density to complete the object clustering, that is based on the density of the growing cluster around an object (such as DBSCAN). Density-based clustering method can be divided into two types: one is based on density clustering of high-density connecting areas; another is based on clustering density distribution function.

(4) Grid-based clustering: first, the object space is divided into a finite number of elements to form a grid structure, and then, clustering is completed by using the grid structure [1].

Fuzzy Clustering Analysis

"People are fetched in groups, similar objects are flock together", the clustering problem is an ancient problem, and is a problem, which is gradually deepening, accompanying the development of human. While human want to understand the world, we must distinguish between different things and recognize similarities among things. Traditional clustering analysis is a hard division, it is the identification of each object of nature to be strictly divided into a class with one or another, the boundary of this classification category is distinct. In fact, there is no strict property of most objects and they exist intermediary in terms of behavior and generic. In other words, it might be suitable for soft division. Fuzzy set theory proposed by [2] Zadeh for such soft division provides a powerful analytical tool, researchers began to use fuzzy clustering method to deal with the problem, and named it as fuzzy clustering analysis. Since samples which fuzzy clustering obtained from uncertainty degree belonging to different categories, it stands for the sample generic intermediary. Namely, the uncertainty description of a sample is established, and it can relatively objectively reflect the real world.

Literatures [3-5] point out that an appropriate classification should match the following three conditions:

(1) Reflexivity: that is any object must own kind: the mathematic definition is $I_{ii} = 1$;

(2) Symmetry: if the object *a* is in the same class to the object *b*, and also *b* is in the same class to *a*: the mathematic definition is $I_{ij} = I_{ji}$;

(3) Transitivity: if the object *a* is in the same class to the object *b*, and the object *b* is in the same class to the object *c*, and then *c* is in the same class to *a*: mathematical definition is $I \cdot I \subseteq I$. While satisfying the above conditions is an equivalence relation, so the fuzzy clustering analysis is conducted based on fuzzy equivalence relation.

The main steps of fuzzy clustering are shown as follows: Firstly, the method is to determine the objects of the classification, and to extract the factor data: setting all classified objects as $x = \{x_1, x_2, \cdots, x_n\}$, and each object x_i consists of a set of data $x_i = \{x_{i1}, x_{i2}, \cdots, x_{im}\}$. Secondly, it is to build the fuzzy similarity relation, namely to describe the similarity of objects x_i and x_j with the value $r_{ij} \in [0,1]$, so that the fuzzy similarity matrix $R = (r_{ij})_{n \times n}$ is obtained, in which, $r_{ij} = r_{ji}$ and $r_{ii} = 1$. There are several commonly used methods to determine r_{ij} the methods, including number product method, correlation coefficient method, maximum and minimum method, arithmetic mean minimum law method, the minimum geometric mean method, the absolute index, the absolute value subtraction method, and subjective evaluation method. These methods are described in detail can be found in the literature [3]. Finally, it classifies according to the fuzzy similarity matrix. In general, the fuzzy clustering analysis should be at a certain level parameter α, thus the α sectional matrix R_α of fuzzy similar matrix R concept is introduced, the elements $r_{\alpha ij}$ of R_α are defined as follows:

$$r_{\alpha ij} = \begin{cases} 1 & r_{ij} \geq \alpha \\ 0 & r_{ij} < \alpha \end{cases} \qquad \alpha \in [0,1]$$

From the definition of fuzzy similarity matrix R, it is obvious that its reflexivity and symmetry can be satisfied, but the transitivity cannot be satisfied. Thus, the α sectional matrix R_α of the fuzzy similar matrix R obtained also satisfy reflexive and symmetric, but not transitive.

In order to obtain R_α satisfied the transitive, that is to get the final classification relationship , there are three algorithms: equivalence closure method , the maximum spanning tree method , and netting method. Equivalence closure is to calculate the power of the fuzzy similar matrix R, such as $R^2, R^4, R^8, \cdots, R^k, R^{2k}$, until $R^k = R^{2k}$ so far. Here, R^k obtained at this time means the fuzzy equivalence relation of the fuzzy similarity relation R, taking its matrix $(R^k)_\alpha$ to get the final classification relationship. This method contains a strict mathematical basis, and it is deduced from the so-called "transitive closure" theory. The proof in detail, see [3]. However, because this method

requires computing power of fuzzy similarity matrix R, which calculations increase exponentially with the number of objects increasing, it is not a good algorithm. Maximum Spanning Tree is directly from the fuzzy similar matrix R to start method by using graph theory to obtain the final classification relationship. It is very intuitive, but it must draw, so it is not suitable for programming applications. Netting Act is from the α sectional matrix R_α of the fuzzy similar matrix R, adopting special drawing mode - netting to solve classification problems. Also, since this method must draw, it is not suitable programming application. Therefore, it is necessary to find a fuzzy clustering algorithm for analysis with small amount of calculation and suitable for programming.

Fuzzy Clustering Method in Data Mining

In practice, the methods based on the objective function are widely applied. These algorithms are generally based on the function of objects between similarity and dissimilarity as the division criteria. By converting the clustering problem into the function optimization problem of the extremum of objective function, the cluster center and membership grade are alternatively iterated in the search space, until convergence presents, which obtained final clustering division. Among the clustering algorithms based on the objective function, the theory of the FCM algorithms is the most perfect, and these algorithms are most widely used. This method classifies the clustering into a nonlinear programming problem with constraints by optimizing the data set obtained and solving fuzzy division and clustering [6-8].

A fast fuzzy C-means clustering algorithm based on the FCM algorithm is presented. Fast Fuzzy C-means clustering algorithm is the fuzzy C-means clustering algorithm by adding a layer in front of hard C-means algorithm. Fuzzy C-means clustering algorithm is developed from the hard C-means algorithm, comparing with hard clustering, fuzzy clustering can get richer clustering information, but the algorithm complexity is significantly increased. Fast Fuzzy C-means clustering algorithm is not only retaining the original fuzzy clustering information-rich C-means clustering algorithm, but also jointing the fast convergence properties of hard clustering. That means it is very meaningful for clustering studies of a large number of data.

Fast Fuzzy C-means clustering algorithm is divided into two layers; steps in detail are as follows:

Determining the number of clusters $c, 2 \le c \le n$ and n is the number of data items;

Setting classification matrix $U^{(0)}$ $\mu_{ik} \in \{0,1\}$, $\sum_{i=1}^{c} \mu_{ik} = 1$ and $1 < \sum_{k=1}^{n} \mu_{ik} < n \quad \forall k$;

Taking $b = 0, 1, 2, \cdots$ in order;

According to $U^{(r)}$ and the following formula $v_i^{(r)}$:

$$v_i^{(r)} = (\sum_{k=1}^{n} \mu_{ik} x_k) / (\sum_{k=1}^{n} \mu_{ik}) \tag{1}$$

Updating $U^{(r)}$; Calculating the updated property function (for all i, k)

$$\mu_{ik}^{(r+1)} = \begin{cases} 1 & d_{ik}^{(r)} = \min\left\{d_{jk}^{(r+1)}\right\} \ j \in c \\ 0 & others \end{cases} \tag{2}$$

Algorithm of the second layer

$$J(U, V) = \sum_{k=1}^{n} \sum_{i=1}^{c} \mu_{ik}^{m} d_{ik}^{2} \tag{3}$$

In that $$d_{ik}^2 = \|x_k - v_i\|^2 = (x_k - v_i)^T A (x_k - v_i) \tag{4}$$

Bringing $v_i^{(b)}$ determined in the algorithm of the first layer to the algorithm of the second layer;

Setting weighted exponent m and the matrix A in (4);

For any fuzzy clustering matrix $U^{(0)}$ $\mu_{ik} \in [0,1]$, $\sum_{i=1}^{c} \mu_{ik} = 1$, $0 < \sum_{k=1}^{n} \mu_{ik} < n$, $\forall k$;

Updating by following methods $U^{(b)}$ for $U^{(b+1)}$ （with $k = 1 \sim n$）：

(a) Calculating I_k and $\overline{I_k}$:

$$I_k = \{i \mid 1 \le i \le c, \quad d_{ik} = 0\} \tag{5}$$

$$\overline{I_k} = \{1,2,\cdots,c\} - I_k \tag{6}$$

(b) Calculating the new membership grade of x_k :

If $I_k \neq \phi$ (empty), then

$$\mu_{ik} = 1 \Big/ [\sum_{j=1}^{c} (d_{ik} / d_{jk})^{2(m-1)}] \tag{7}$$

Otherwise, for all $i \in \overline{I_k}$, set $\mu_{ik} = 0$, and taking

$$\sum_{i \in I_k} \mu_{ik} = 1 \qquad k = k + 1$$

Comparing $U^{(b)}$ and $U^{(b+1)}$ with an appropriate matrix norm;

if $\left\| U^{(b)} - U^{(b+1)} \right\| < \varepsilon$, stop; otherwise, set $b = b + 1$ and return to the step , here ε represents a predefined allowed deviation.

Summry

In the pace with data mining technology growing up, the implied and meaningful knowledge discovery from the databases has become the main objective of data mining. This article discusses how the various types of data in the database are processed, and then apply the theory of fuzzy clustering relationships to gain useful knowledge. Its basis is no longer the FCM algorithm, but presents a fast fuzzy C-means clustering algorithm based on the FCM algorithm. Fast Fuzzy C-means clustering algorithm combines simplicity and speed of hard clustering and complex comprehensiveness of fuzzy clustering, so that it make the improved algorithm not only retaining the original rich fuzzy C-means clustering algorithm clustering information, but also jointing the fast convergence properties of hard clustering. Therefore, the introduction of data mining in this fuzzy clustering method conducts repeatedly scanning against the database without multiple iterations repeated calculations, greatly improving the computational efficiency, and convergence is very fast. It is meaningful for processing big data.

Keywords: femtocell; clustering; game theory; spectrum allocation; power control

Abstract.

In order to mitigate the downlink interference in two-tier femtocell networks, a joint spectrum and power allocation algorithm based on graph and game theory is proposed in this paper. On the premise of ensuring the QoS (Quality of Service) of MUEs (microcell user equipments), we first adopt graph-based clustering algorithm to assign subbands to femtocells. Then, for femtocells of each cluster, their transmitting power is redistributed based on the non-cooperative game theory to further reduce the interference among them. Simulation results show that this algorithm can further improves the performance of the entire system compared with pure clustering strategy and ensures the QoS of MUEs at the same time.

Introduction

Studies show that about 2/3 voice traffic and more than 70% data traffic occur indoors in microcell networks. And this proportion will rise further as people's demand for data services increases [1]. Femtocells have been devised to provide good coverage in indoor environments with stable propagation channels and low mobility [2]. It is installed by users, and possesses the features of small size, low cost and low power consumption. Due to their short transmit-receive distance, femtocells can greatly lower transmit power, prolong handset battery life, and achieve a higher signal-to-interference-plus-noise ratio (SINR) [3].

There exist many challenges before femtocells can be put into large-scale commercial. Due to the self-deployment and close locations of femtocells, their interference environments are more complicated than traditional wireless networks [4]. Because of the limitation of frequency resources, femtocells have to share the spectrum with microcells, which leads to the existence of cross-tier interference. To manage with the interference, we have to distribute the resources reasonably. At present, many literatures have studied the spectrum allocation and power control methods for femtocells. Literature [5] raises an improved graph coloring algorithm: the potential maximum chromatic number strategy. It combines the advantages of Improved SEQ and DSATUR algorithms. The effect is that it saves more frequency resources with little complexity difference from traditional algorithms. One shortcoming is that the proportional coefficient in it needs to be adjusted according to the given situation to get a better performance. Literature [6] proposes a graph-based dynamic frequency reuse method. It designs a kind of cost function which takes into account the usage efficiency of spectrum. First, each FBS (femtocell base station) acquires one subband according to the cost function. Then, this function is used to reallocate subbands which can be reused. Although it has better performance than traditional graph coloring algorithms, it appears to be more favorable to FBSs which suffer more interference. This leads to lower spectrum utilization rate. Literature [7, 8] use graph-based clustering algorithm to allocate subbands to femtocells. Compared with traditional coloring algorithms and the algorithm in [6], clustering can significantly improve the capacity of femtocells. However, the transmitting power of each FBS on each subband it uses is equal and constant. This is not conducive to subbands which suffer less interference and can possibly get more power within the permissible range.

This paper proposes a joint spectrum and power allocation algorithm for femtocells. Assuming MUEs can use all subbands. For femtocells, we first establish their interference graph according to the interference situation of them. Then, subbands are reasonably allocated to FBSs based on clustering strategy. On this basis, each FBS's transmitting power on each subband it owns is further adjusted using game theory. Finally, the MUEs and FUEs' capacity is improved while QoS of MUEs is ensured.

System model

Consider the two-tier network model, where microcells and femtocells share the whole spectrum resources. We study the downlink resource allocation and use Suburban model of which each femtocell's coverage area is a circle with fixed radius and femtocells are randomly distributed within the coverage of the microcell [7].

As shown in figure 1, we only consider one microcell (ignoring the interference from adjacent microcells) with the coverage radius and maximum transmitting power p_m. There are M MUEs and F femtocells deploying randomly in the microcell. Femtocell's coverage radius is r. FBSs' maximum transmitting power is p_f. Each femtocell owns one FBS locating in its centre and one FUE deploying randomly. Without loss of generality, we assume the number of subbands equals the number of MUEs and each MUE is assigned with a different subband. FBS's transmitting power on each subband can be different, but the summation must not exceed p_f.

The Closed Subscriber Group (CSG) configuration mode is adopted. Figure 1 gives the downlink interference situation in two-tier network.

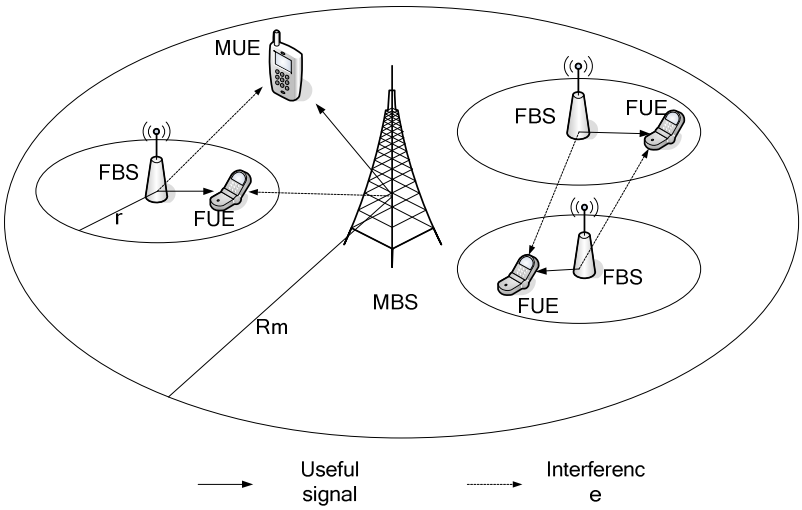

Fig. 1. The two-tier network model

SINR of MUE m on subband i is determined as

$$\gamma_{m,i} = \frac{p_{M,i} * h_m^{MM}}{\sum_{f=1}^{F} p_{f,i} * h_{f,m}^{FM} + N_0 * B} \tag{1}$$

where $p_{M,i}$ is the transmitting power of MBS on subband i; h_m^{MM} is the channel gain between MBS and MUE m; $p_{f,i}$ is FBS f's power on subband i; $h_{f,m}^{FM}$ is the channel gain between FBS f and MUE m; N_0 is the thermal noise density and B is bandwidth of the subband.

Since MUEs use all the subbands, FUEs will definitely be interfered by MBS. So, SINR of FUE f on subband i is written as

$$\gamma_{f,i} = \frac{p_{f,i} * h_f^{FF}}{\sum_{n=1,n\neq f}^{F} \eta_{n,i} * p_{n,i} * h_{nf}^{FF} + p_{M,i} * h_f^{MF} + N_0 * B} \tag{2}$$

where h_f^{FF} is the channel gain between FBS and its accessorial FUE f; h_{nf}^{FF} is the channel gain between FBS n and FUE f; h_f^{MF} is the channel gain between MBS and FUE f. We assign 0 to $\eta_{n,i}$ when FBS n can't use subband i. Otherwise, we assign 1 to it.

When MUE m's SINR reaches its threshold, the interference it suffers from femtocells can be written as

$$I_{fth} = \frac{p_{mr}}{SINR_{mth}} - N_0 * B \tag{3}$$

where p_{mr} is the m's received power; $SINR_{mth}$ is MUE's SINR threshold. Based on fairness, we assume that each of the FBSs which use the same subband as m causes the same amount of interference to it. The interference from each of them is $I_{fpth} = \frac{I_{fth}}{F}$. Then, we can obtain the maximum transmitting power these FBSs can use on the subband used by MUE m: $p_{mi} = \frac{I_{fpth}}{h_{f,m}^{FM}}$.

The calculation formula of spectral efficiency is based on literature [6]. This paper only considers large scale fading. Channel propagation model is based on literature [8].

Joint spectrum and power allocation algorithm

Spectrum Allocation. Spectrum is allocated to femtocells according to graph-based clustering strategy [7]. In the beginning, FBSs can use all the subbands and power allocated on each subband is equal. First, we establish the interference graph of femtocells. Then, we use clustering to allocate subbands to FUEs based on the interference graph. More details will be given in the next section.

Power allocation. After clustering, each cluster represents the corresponding subband and MUE. Only FBSs in the cluster can cause interference to the MUE which the cluster corresponds to. To increase system's performance, we redistribute the power of each FBS on their available subbands based on game theory.

The utility function is based on literature [9]

$$u_f = \ln(\gamma_m - \gamma_{thm}) + \ln(\gamma_f - \gamma_{thf}) - k * p_f * (h_{f,m}^{FM} + \sum_{n=1,n\neq f}^{F} h_{f,n}^{FF}) \tag{8}$$

where γ_m and γ_f represent the SINR of MUE m and FUE f individually; γ_{thm} and γ_{thf} represent the SINR threshold of MUE and FUE individually; k is the weighting factor to balance the two parts of the equation. FBSs included in the utility function are elements of the cluster which m represents. Then, we can get the iterative formula as follows [9]

$$p_f^{(n+1)} = \frac{\gamma_{thf} * p_f^{(n)}}{\gamma_f^{(n)}} + \frac{1}{k * (h_{f,m}^{FM} + \sum_{n=1,n\neq f}^{F} h_{f,n}^{FF}) + \frac{(\gamma_m^{(n)})^2 * h_{f,m}^{FM}}{(\gamma_m^{(n)} - \gamma_{thm}) * p_{mr} * h_m^{MM}}} \tag{9}$$

s. t. : $p_{f\min} \le p_f^{(n+1)} \le p_{f\max}$

where n and $n+1$ represent the number of iterations; $p_{f\min}$ is obtained by dividing FBS's maximum transmitting power by the number of all subbands; $p_{f\max}$ is written as

$$p_{f\max} = \min(p_{fm}, p_{mi}) \tag{10}$$

of which p_{fm} is obtained by dividing FBS's maximum transmitting power by the number of subbands it has access to use.

Algorithm Process

The algorithm's steps are given as follows.

Step 1. Adjust FBSs' color sets according to MUEs' SINR. When a MUE's SINR does not meet the requirement, remove the FBS which causes the maximum interference until the SINR exceeds the threshold. Those removed FBSs cannot use the same subband as this MUE.

Step 2. Adjust FBSs' color sets according to the interference they suffer from the MBS. If MBS causes serious interference to a FBS that this FBS's SINR cannot meet the requirement, then this FBS has no subband to use.

Step 3. Establish femtocells' interference graph. When a FBS does not meet the requirement of SINR, remove the FBS which causes the maximum interference to it until its SINR exceeds the threshold. Also, there will be edges established between this FBS and the FBSs removed. That means both sides cannot use the same subband.

Step 4. Use clustering strategy to distribute subbands to femtocells based on the interference graph we establish in step 3. Each color represents a cluster. Elements in the cluster can use the subband the cluster represents. If there exists a edge in the cluster, then keep deleting the FBS which owns the maximum adjacent FBSs until no edge exists in the cluster. In this way, we accomplish the clustering. FBSs belonging to the cluster will get the subband it represents.

Step 5. Assuming that the original power of each FBS on each subband is its maximum transmitting power divided by the number of all subbands.

Step 6. Take each cluster as a unit, iterate the power of FBSs on their accessible subbands with equation (10).

Step 7. After iteration if there exists one FBS's power exceeds the power before iteration by 10^(+8)w, then the convergence is reached and the algorithm terminates. Otherwise, return to step 6.

Of which, step 1 to step 4 are steps of allocating spectrum, and step 5 to step 7 are steps of allocating power.

Simulation results and analysis

Simulation scene of this paper is one microcell with three sectors. Because those sectors have the same distribution, so we only consider one sector. Assuming that femtocells are randomly distributed in a annular region which is R_f far from MBS, and M =60.

Part of the parameters to calculate the path loss are based on literature [6] and [8]. The rest of them are listed in table 1.

Table 1 Simulation parameters

$R_m, R_f, r[m]$	500, 250, 30
$P_m, P_f[dBm]$	46, 20
$N_0[dBm/Hz], B[Hz]$	-174, 0.18*10^(6)
$\gamma_{thm}, \gamma_{thf}[dB]$	6, 8

We compare three kinds of algorithms. The first one only considers clustering. Power allocated on each subband is equal. The second one considers clustering at first. The power of each FBS on each subband it owns is transformed to its maximum power divided by its accessible subbands. The third one is the algorithm we have proposed. These three algorithms are referred as algorithm 1, algorithm 2 and algorithm 3 in the remaining parts of the paper.

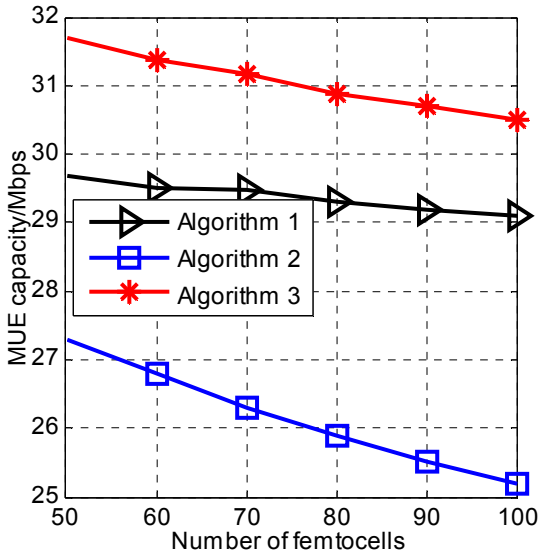

Fig. 2. MUEs' capacity with different number of FBSs

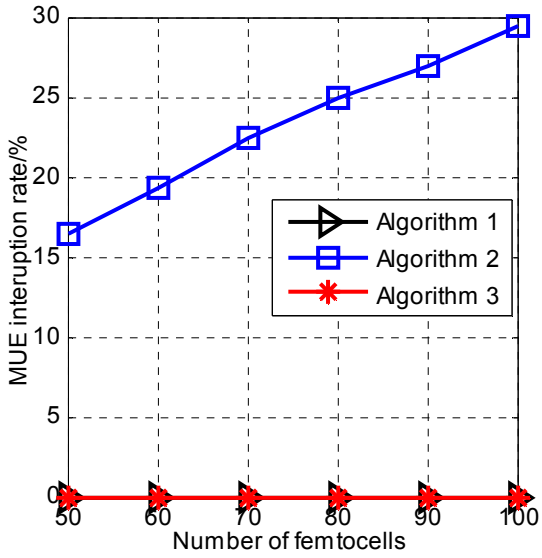

Fig. 3.MUEs' interruption rate with different number of FBSs

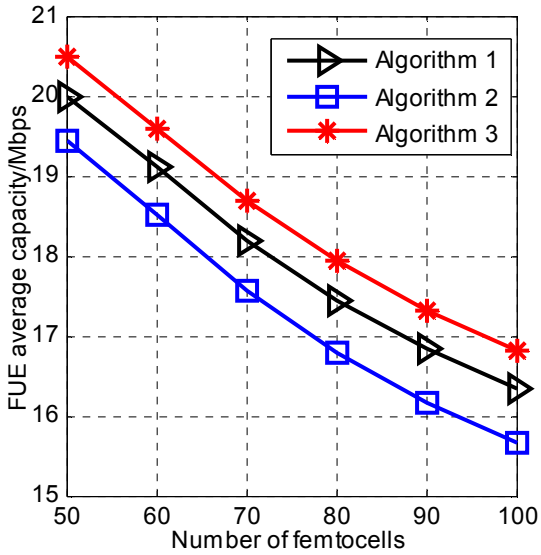

Fig. 4. Per FUE's average capacity with different number of FBSs

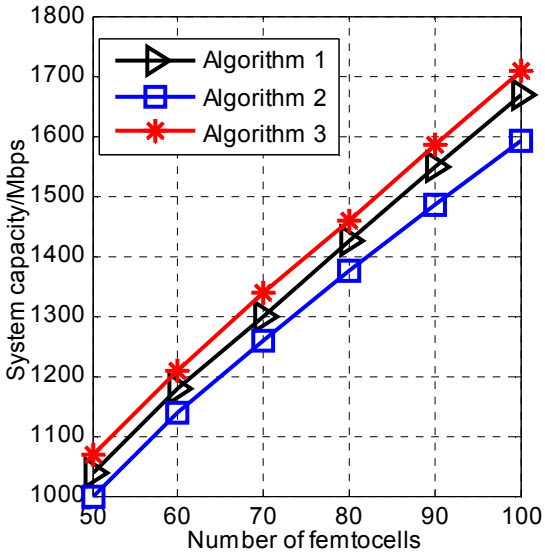

Fig. 5. System's capacity with different number of FBSs

Figure 2 and figure 3 show the change curves of MUEs' capacity and interruption rate with different number of FBSs. We can see from figures that algorithm 1 and 3 can guarantee the MUE capacity and QoS much better than algorithm 2. Algorithm 1 adjusts FBSs' available subband sets according to MUEs' SINR to ensure all MUEs' QoS, so its interruption rate is zero. Algorithm 3 ensures the power of FBSs on each subband they own will not exceed the threshold we set. In this way, MUEs' QoS is also guaranteed. Also, the utility function is of advantage to MUEs' capacity. However, in algorithm 2, the power of FBSs on each subband they own all rises which leads to more interference to MUEs.

Figure 4 and figure 5 show the change curves of per FUE's average capacity and system's capacity with different number of FBSs. Along with the number of FBSs increasing, we can observe that per FUE's capacity overall downward trend. The reason is that the distribution of FBSs becomes more intensive which causes more interference among femtocells. Algorithm 1 only considers clustering and the power of FBSs is not fully utilized. Algorithm 3 distributes power resources according to the actual scene of femtocells in order to further raise FBSs and MUEs' SINR. Because the total capacity of FBSs overall upward trend, system's capacity overall upward trend.

From these four figures, we can learn that algorithm 3 owns the best performance.

Summary

This paper proposes a joint spectrum and power allocation algorithm based on graph and game theory for femtocell. First, we allocate subbands to femtocells based on clustering. Then, the transmitting power of FBSs on each subband they own is redistributed based on game theory in order to fully use the resources. The simulation results show this algorithm performs better in increasing the capacity of MUEs and FUEs compared with pure clustering algorithm. However, this algorithm still needs to be improved. Although MUEs have better performance, the increase of FUEs' capacity is not very ideal. We need to seek a better utility function next step which is more favorable to increasing FUEs' capacity while ensuring MUEs' QoS.

Key words：virtual reality; human-computer interaction; data glove; collision detection

Abstract：The virtual reality technology is used in the mine training simulation areas, which can overcome the limitations of traditional training methods effectively. It can also improve the quality of mine training simulation greatly, reduce training costs, and the users can achieve safe and convenient training. In this paper, a dynamic collision detection algorithm is proposed based on the prediction of the movement direction of a virtual hand, and it is the effective collision detection algorithm using data glove in the mine training simulation system. Compared with the traditional static collision detection algorithm in the performance, the dynamic algorithm is proposed to solve the collision detection between one simulation solid model and another one, and to achieve the function that a virtual hand grip and rotate virtual objects in the virtual environment. The dynamic collision detection algorithm can be extended to other simulation systems.

Introduction

Human-Computer Interaction (HCI) involves the study, design and interaction between users and computers. Human is the leader in the communication process, who operates a computer to complete commands and requirements. The paper about computer console design was firstly proposed by the American scholar B. Shackel in 1959, with the development of half a century, the HCI has been improved from the stage of people adapting to the computer to the stage of computer adapting to human. In this process there is a growing emphasis on the friendly interaction. With the development of HCI, virtual reality technology [1] has also been developing rapidly. It urgently needs a new way of the human-computer interaction. Virtual reality technology is the way that a computer technology as the core, combined with relevant science and technology to produce a digital environment in which the real environment is highly approximated in the aspects of certain range vision, hearing, and touch. Any user with the necessary equipment and any object in the digital environment interact and influence each other, and the user can feel and experience the real environment.

In order to tell the worker what proper measures can be taken in the dangerous accidents, meanwhile, people wouldn't allow reproducing some unexpected risk incidents happened in the real work environment, so we use the virtual reality technology to develop a virtual simulation training system and use the latest computer graphics technology to accurately reproduce the virtual scene of coalbed methane gathering. Through somatosensory input devices, such as data glove, the system can achieve human-computer interaction, at the same time, the user get the feelings of practical operation. Through the system that contains a number of virtual dangerous accidents designed, users can witness these terrible accidents and strengthen their safety awareness, which is impossible to experience in the traditional training. As a kind of visualization tool, virtual reality can make the

human-machine interface of the operating system more humanized. In the early virtual reality system, mouse and keyboard are the primary input devices, and CRT monitor is the primary output device. In order to make the system more flexible, more convenient and more real-time, data glove, stereoscopic glasses, Kinect and other equipment are used in our system.

The HCI process of data glove

Data glove can get locations, directions and gestures of fingers and palm through sensors, at the same time, the data of glove are being sent to the computer. The computer controls the virtual hand [2] which can make the corresponding gestures and movements in the virtual environment by using the data. The HCI process of 5DT data glove shows in Fig. 1.

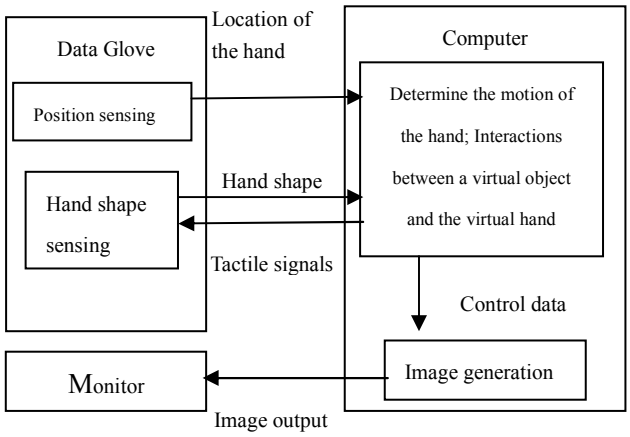

Fig. 1 The HCI process of 5DT data glove

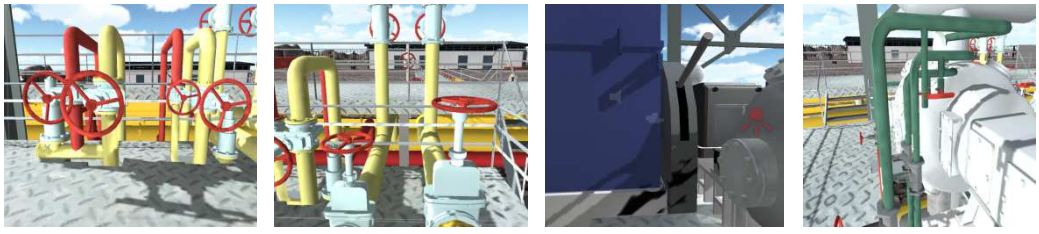
Collision Detection

In the virtual reality, if the users feel the virtual objects in the digital environment is “real object”, and then we can say that the users have a strong sense of immersion. In order to achieve this goal, collision detection is a key. It requires that the system can determine precisely, completely and real-time whether there is a collision among virtual objects.

Virtual object and virtual hand

The equipment which we can see everywhere in CBM (coalbed methane) surface gathering scene are all kinds of pipelines and valves. The steps of operating a compressor show in Fig.2. Firstly, opening the intake valve and the vent valve; secondly, opening the barring gear; at last, opening the exhaust pipe. These particular structural models which all need collision detection are built in the system.

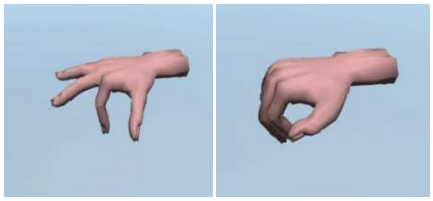


(a) Intake valve (b) Vent valve (c) Barring gear (d) Exhaust pipe

Fig. 2 Compressor

The models which show in Fig. 2 are rigid bodies [3]. Once the models whether dealing with the force terms or not are created out, the distance between one point and another in the rigid body

interior will not change, as well as the shape of rigid body. However, the soft body which is different with the rigid body will change if it has been applied a external force. So Virtual hand can be regarded as a kind of soft body, because the virtual hand will have the corresponding change based on the gesture change of user's hand. In other words, deformation will occur to the virtual hand dealing with the force terms, as show in Fig.3. Compared to collision detection of the rigid body, collision detection of the soft body is more complicated. When deformation of the soft body occurs, the relative position of the vertices will change, it makes collision detection algorithms of the rigid body cannot be directly used to soft body. While the virtual hand is a dynamic object whose position and orientation depends on the control of users. The problem how to judge whether there is an interaction between two collision models in the sampling time needs to be considered. A dynamic collision detection algorithm based on the prediction of the movement direction of a virtual hand was proposed in this paper，and the result shows that the algorithm can solve this problem.



(a) (b)

Fig. 3 Virtual hand

The dynamic collision detection algorithm

1. Add bounding box

Virtual hand is trying to mimic the natural bone structure and motion characteristics of the real human hand in the simulation system. The human hand in real world can be divided into a palm, a wrist and five fingers. In order to build model easily, the system simplifies the structure of the virtual hand [4]. The virtual hand is divided into two parts: a palm and five fingers. And then each finger is divided into two or three finger segments. Note that each finger has three finger segments except that the thumb has two finger segments.

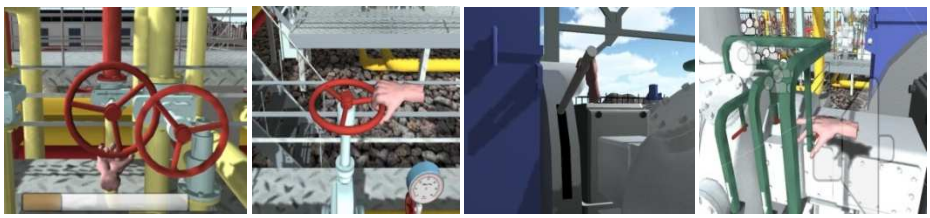
According to the bone structure of the human hand in real world, we found that fingers occur bending when a hand grips an object. Meanwhile there is no deformation occurred in each segment of fingers, but the joint connected two finger segments has been bended. In the system, when the virtual hand grabs the object, the change of palm of the virtual hand can be negligible, so a virtual hand can be consisted of a palm and 14 finger segments which have no deformation. According to this, we add the Sphere bounding box and the *OBB* bounding box [5] to the virtual hand. Each finger segment is added an *OBB* bounding box, and the palm is added a Sphere bounding box, while the virtual object in the virtual environment is added a *K-dop* [6] bounding box. In the system, the collision detection between *OBB* and *K-dop* bounding box is used as the basic collision detection as well as the collision detection between the Sphere and *K-dop* bounding box. Therefore, we can solve the problem that the soft body cannot use a rigid body collision detection algorithm directly. And the result shows that the dynamic collision detection algorithm we proposed can improve the efficiency of collision detection in the virtual environment.

2．Algorithm implement

Here is the Pseudo-code of the dynamic collision detection algorithm based on the prediction of the movement direction of a virtual hand.

```
//Awake is called when the script instance is being loaded, and it is called only once during the lifetime of the script instance.
void Awake() {
//Set the values of the contact tags of the fingers and record the end positions of the fingers.
    for (i=0; i<5; i++){
    Collision_B[i] =false;
    OldPosition_B[i] = Vector3 (e[i].X, e[i].Y, e[i].Z); }
//Set the value of the contact tags of the palm and record the center positions of the palm.
    Collision_P=false;
    OldPosition_P = Vector3 (e.X, e.Y, e.Z);
//Set the value of the tag is true, if the virtual hand is close to the collision object.
    CloseToObject = true ;}
// Update is called every frame.
void Update() {for (i=0; i<5;i++){
    if (Collision_B[i] || Collision_P)
//Determine the movement direction of the virtual hand, if it is still close to the collision object.
        {if (CloseToObject) {return ;}
            else {Collision ();
            Position () ;}}
        else{Collison();
            Position();
            SetTags () ;}}
    CurrentPosition_B[i] = OldPosition_B[i];
    CurrentPosition_P = OldPosition_P ;}
void Collision() {//Do the basic collision detection.}
void Position() {//Record the position of the virtual hand.}
void SetTags() {// Set the values of the contact tags.}
```

The algorithm can meet the needs of the virtual interaction system. The collision between the virtual hand and the virtual object can be detected flexibly and rapidly. Only when the collision is detected and the prerequisites of the virtual hand griping the virtual object have been achieved, the system will determine whether to grip the virtual object, and the simulation of rotating a valve and pulling down a barring gear will be achieved finally. The dynamic collision detection algorithm is well applied in the CBM simulation training system, and the screenshots of results are shown in Fig.4.



(a) (b) (c) (d)

Fig. 4 The interaction between the virtual hand and the virtual objects

Results

In order to comparing the performance of the traditional static collision detection algorithm with the dynamic algorithm which we proposed, we use the same data glove to grip a virtual object

in different directions at different points, and repeat the same action many times. The collision data of the two algorithms is recorded in every time. We found that the triangular facet connected the virtual hand and the virtual object cannot be detected in the traditional static algorithm, on account of the virtual finger will go into the interior of the virtual object. However, the dynamic collision detection algorithm will avoid such a situation happen, and its detection effect is more accurate and more obvious. The result shows as Table 1.

Table 1 The comparison result of the two algorithms

Collision algorithm	The number of collision	Success rate
The traditional static collision detection algorithm	100	82%
The dynamic collision detection algorithm	100	93%

Conclusion

In this paper, the CBM ground gathering simulation training system is used as the background. A dynamic collision detection algorithm which is used in the CBM industry simulation system is proposed, and detailed description of the algorithm is made. The performance comparison of the traditional static collision detection algorithm and our algorithm demonstrates that the dynamic collision detection algorithm has been significantly improved on the overall performance. The dynamic algorithm has broad applicability, and it can be extended to other simulation systems.

Keywords: N-Gram Model, T9 Input, Training Set

Abstract. In this practical, a program of t9-like recognition of a word will be implemented. The n-gram model will be adopted for the recognizing process. Finally, the program will be evaluated for both types with smoothing and no smoothing.

Introduction

I have tried to use nltk.book at the beginning. However the corpus of each of the books might be very limited. In most academic material, the research would like to choose one corpus from corpora of nltk. Therefore, a corpus – brown, has been finally selected as a training set.

When a number will be transformed as a word with t9 rules, there might be too much possibility to calculate according to an n-Gram model. That means the possible words could be a long list. A consideration of eliminating those which are non-word in English was generated. Hence a dictionary might be required to check them. Dictionaries such as wordnet and enchant are available to be adopted here. The dictionary enchant for python 2.7.3 (my version) is required to install a package pyenchant-1.6.5.win32.exe, it might not be suitable for different testing environment. Therefore, the wordnet was chosen in this practical, although there are some word cannot be found in it.

N-Gram

The implementation with bigram model was developed at the beginning of this practical, and then it universalized as n-gram model. So an issue related to processing the first letter for 3 (or more) grams model was raised. For example, the probabilities have to be calculated as following for 3 grams model:

p(c1|<s>)
p(c2|<s>c1)
p(c3|c1c2)
…

c1 means char 1(or letter 1); <s> represents the beginning of a word, in this practical, it is a space(see python code). Other models more than 3 grams are similar with the previous calculation listed.

Evaluation

For testing how good the t9() algorithm is, a testing word set, which is different from the training set as a justifiable fundamental, will be selected from other corpora in nltk such as *reuters* and *webtext*. In this practical, they all were chosen and limited by the top 200 words. The each word in the testing set from those corpora will be converted into a number string. By calling the t9() function with this string, a new word will be obtained. The comparison of the returned words and the corresponding original words could result a correct rate. The rates of, different models with number of grams, and smoothing or non-smoothing, could be compared.

Smoothing

In this practical, the add-one smoothing was implemented as an experimental instance. The smoothing formula for the probability as the following,

$$p^*(c_i|c_{i-1}) = \frac{C(c_{i-1}c_i)+1}{C(c_{i-1})+V} \quad (1)$$

p^* means the probability with smoothing; $C(c_i)$ means the number of char i (or letter i); $C(c_{i-1}c_i)$ means the number of the combination of char i-1and char i. V represent the total number of chars in training set. The add-one smoothing could allow the calculation to result a non-zero probability to unseen words in the training set.

Results

2-Gram and 3-Gram.

Table 1 Results of 2-Gram and 3-Gram models

200 word no smoothing	2-Gram	3-Gram
Total right	98	86
Total legal	172	172
Correct rate	0.5698	0.5

This testing set is of top 200 words from reuters corpus. The "**Total legal**" means the number of words which is after remove those non-word chars such as comma and period. The correct rate of 2-gram is over 10 % more than 3-gram**. That means 3-gram model might not be better than 2-gram for guessing word with t9 rules.**

Smoothing and Non-smoothing.

Table 2 Result of 2-Gram with Smoothing and without Smoothing

200 word with 2-Gram	Smoothing	Non-smoothing
Total right	99	98
Total legal	172	172
Correct rate	0.5756	0.5698

There is no significant improvement with smoothing for 2-gram model.

Table 3, Result of 3-Gram with Smoothing and without Smoothing

200 word with 3-Gram	Smoothing	Non-smoothing
Total right	95	86
Total legal	172	172
Correct rate	0.5523	0.5

Correct rate is much better with smoothing for 3-gram model.

That is smoothing strategy might much more improve the correct rate for 3-gram model of t9 word guessing.

Long words.

Long word list is as the following words.

- correspondents (26773776633687), more than 1 minute
- protectionist (7768328466478), about 30 second
- semiconductors (73642663828677), more than 1 minute
- representatives (737737368284837), out of memory (top 200 in inaugural corpus)

Guessing a long word might lead to a long time consuming or an out-of-memory error.

Dictionary Issue.

There some word could not be found in the dictionary *wordnet.* For example, the word-"*that*" cannot be found in it. If there is a word cannot be found in the dictionary, a null string will be returned. **That means the dictionary selection will impact on the correct rates.**

Conclusions

For guessing word with t9 rules, in this practical, 2-gram model might be better than 3-gram model without smoothing. The smoothing strategy might much more improve the correct rate for 3-gram model. In addition, calculation of a long word might lead to a long time consuming or an out-of-memory error in the guessing process. The selection of a dictionary will impact on the correct rates since it could remove a legal word from candidate list.

Simulation Analysis of Mind Sports Games Based on Artificial Intelligence

Guowen Cui[1], Xinqiang Li[1]

[1]Physical Education Department, Binzhou University, Binzhou, 256603, China

Keywords: Coupling mechanism; Mind sports games; Development mechanism; Model construction; Simulation analysis

Abstract. Mind sports games is rose in recent years, which is the comprehensive sports event taking the chess sports as the main part, and it is a perfect combination of human intelligence and sports art. Due to a simple history of mind sports games, there exists some problems that are the imbalance of development, lack of funds, and event organization difficulty, which has restricted the rapid development of mind sports games. Aiming at the problems of mind sports games encountering in the development, the paper first proposes the coupling development mechanism for the organization of mind sports games and its development mechanism, and then establishes the model of development mechanism based on the coupling reduction mechanism, and the model has been made simulation analysis. At last, the results show that the application of this coupling model can find the bottleneck of the development of mind sports games, so as to open the breakthrough point for its development, and to improve its development level.

Introduction

Coupling refers to a series of complex processes produced by the information parameters controlled each other and the data information transmitted each other between two information modules and data modules. In the practical application, it mainly uses the coupling mechanism to simulate complex production calculation process [1-3]. The construction of coupling mechanism model has greatly simplified the process of calculation, and has increased the calculation efficiency[4]. It can enable people to clearly see the whole production operation process through computer simulation.

The common coupling mechanism includes content coupling, common coupling, external coupling, control coupling, stamp coupling, data coupling, non-direct coupling, and so on [5-7]. These various couplings respectively have different level of dependent on module information, and the coupling strength is also different. It is as shown in Figure 1.

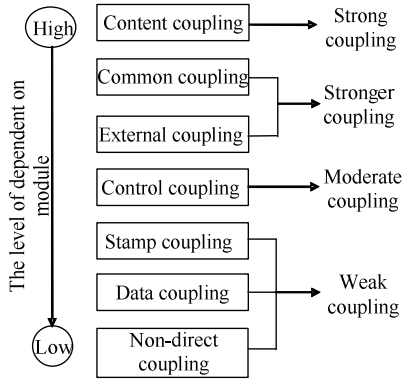

Fig. 1 Schematic diagram of several kinds of common coupling mechanisms

As shown in Figure 1, the level of dependent on module for content coupling, common coupling, external coupling, control coupling, stamp coupling, data coupling, non-direct coupling is gradually reducing [8]. The content coupling belongs to strong coupling, while the degree of coupling of common coupling and external coupling is weaker than that of content coupling. Control coupling belongs to the moderate coupling. Stamp coupling, data coupling and non-direct coupling belong to the weak coupling.Content coupling is totally dependent on the module information which is used to

modify the content coupling. Common coupling requires multiple modules to use a common data set. Control coupling controls other modules through transmitting data information [9,10]. Stamp coupling transmits data information through the module parameters. Data coupling that is similar to stamp coupling transmits data information through the module parameters too. Non-direct coupling has no direct information transmission among modules.

Construction of a Coupling Model for Mind Sports Games Development Mechanism

Although the rank of some intellectual sports level in china is on the front in the world, due to the later rose mind sports games in China, not many involved people, lack of professionals, low level with the coach, these factors have restricted the development of mind sports games [11-13]. In order to promote the rapid development of China's mind sports games, to break the bottleneck that has restricted the development, this paper constructs the model of development mechanism based on the coupling reduction mechanism, where the coupling relationship between the restricting factors and development mechanism is as shown in Figure 3.

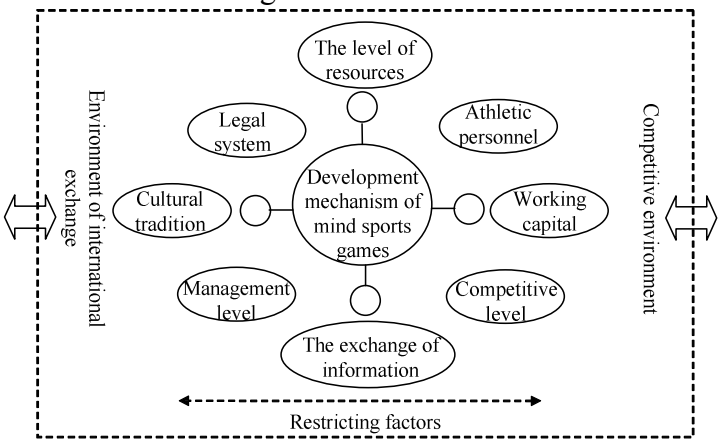

Fig. 3 Schematic diagram of the coupling relationship between restricting factors and development mechanism

As shown in Figure 3, there is the following function relation of the coupling relationship between the restricting factors and development mechanism. The variables of $D_i(i=1,2,\cdots,q)$ is said to be the variable factors of mind sports games development. D_{ij} is the j index of the i ordinal variables, and its value is $E_{ij}(j=1,2,\cdots,f)$, then there exists that

$$D_{ij}=\begin{cases}(E_{ij}-y_{ij})/(x_{ij}-y_{ij})\\(x_{ij}-E_{ij})/(x_{ij}-y_{ij})\end{cases}. \tag{1}$$

After being carried out the linear weighted, and the summation, it can obtain that

$$D_{ij}=\sum_{j=1}^{m}\lambda_{ij}D_{ij}\ \sum_{j=1}^{m}\lambda_{ij}=1. \tag{2}$$

The coupling function is shown as follows

$$C_n=\left\{(D_1\cdot D_2\cdot\cdots D_m)/\left\{\prod(D_i+D_j)\right\}\right\}^{1/n}. \tag{3}$$

$$C=2\left\{(D_1\cdot D_2)/\{(D_1+D_2)(D_1+D_2)\}\right\}^{1/2}. \tag{4}$$

Equation (3) and (4) are substituted into the equation (1), then it can obtain that

$$c_{11}\frac{\partial\varepsilon_x}{\partial_x}+c_{12}\frac{\partial\varepsilon_y}{\partial_x}+c_{13}\frac{\partial\varepsilon_z}{\partial_x}+\frac{1}{2}(c_{11}-c_{12})\frac{\partial\gamma_{xy}}{\partial_x}+c_{44}\frac{\partial\gamma_{zx}}{\partial_x}+(\ell^{31}+\ell^{15})\frac{\partial^2\Phi}{\partial_x\partial_z}=0$$

$$c_{12}\frac{\partial \varepsilon_x}{\partial_y}+c_{11}\frac{\partial \varepsilon_y}{\partial_y}+c_{13}\frac{\partial \varepsilon_z}{\partial_y}+\frac{1}{2}(c_{11}-c_{12})\frac{\partial \gamma_{xy}}{\partial_x}+c_{44}\frac{\partial \gamma_{yz}}{\partial_z}+(\ell^{31}+\ell^{15})\frac{\partial^2 \Phi}{\partial_y \partial_z}=0$$
$$c_{13}\frac{\partial \varepsilon_x}{\partial_z}+c_{13}\frac{\partial \varepsilon_y}{\partial_z}+c_{33}\frac{\partial \varepsilon_z}{\partial_z}+c_{44}\frac{\partial \gamma_{xz}}{\partial_x}+c_{44}\frac{\partial \gamma_{yz}}{\partial_y}+\ell^{15}(\frac{\partial^2 \Phi}{\partial x^2}+\frac{\partial^2 \Phi}{\partial y^2})+\ell^{33}\frac{\partial^2 \Phi}{\partial z^2}=0 \quad (5)$$
$$c_{15}(\frac{\partial \gamma_{xz}}{\partial_x}+\frac{\partial \gamma_{yz}}{\partial_y})+c_{31}(\frac{\partial \varepsilon_x}{\partial_z}+\frac{\partial \varepsilon_y}{\partial_z})+\ell^{33}\frac{\partial \varepsilon_z}{\partial_z}-g^{11}(\frac{\partial^2 \Phi}{\partial x^2}+\frac{\partial^2 \Phi}{\partial y^2})-g^{33}\frac{\partial^2 \Phi}{\partial z^2}=0$$

The above equations are the function expression of development mechanism model for mind sports games based on the coupling reduction mechanism. The model can help avoid the problems of not many involved people, lack of professionals, low level with the coach, and other restricting factors on the development of mind sports games, which is a good model for the rapid development of current mind sports games in china.

Simulation Analysis

The development mechanism model of mind sports games based on coupling reduction mechanism is conducive to break through the constraints produced by external influence factors on the development of mind sports games, and to break the bottleneck of its development [14]. To further verify the model's ability to withstand the external influence factors, it is carried out the analysis of 3D simulation, and the schematic diagram is shown in Figure 4.

As shown in Figure 4, the function expression of the simulation system for the three dimensions of technological innovation, idea innovation, and restricting factors is shown as follows. *xy* dimension system is

$$[c]=\begin{bmatrix} c_{11} & c_{13} & 0 \\ c_{13} & c_{33} & 0 \\ 0 & 0 & c_{44} \end{bmatrix}.$$

xz dimension system is $[e]=\begin{bmatrix} 0 & 0 & e_{15} \\ e_{31} & e_{33} & 0 \end{bmatrix}$.

yz dimension system is $[g]=\begin{bmatrix} g^{11} & 0 \\ 0 & g^{33} \end{bmatrix}$.

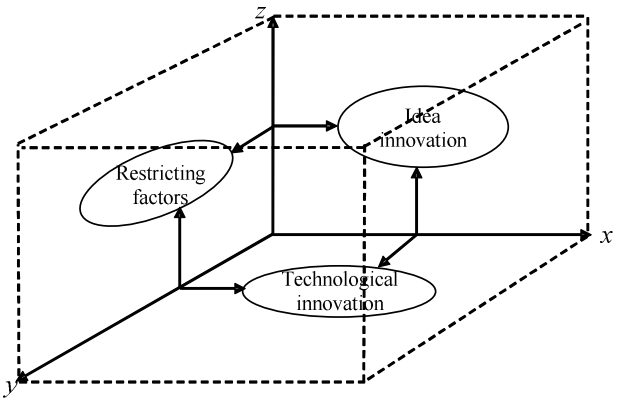

Fig. 4 Schematic diagram of 3D simulation analysis

For the endurance of three dimensions simulation system on the external influence, its function expression is shown as follows.

$$\varepsilon_y=\frac{-c_{12}\varepsilon_x-c_{13}\varepsilon_z+e_{13}E_z}{c_{11}}. \quad (6)$$

The simulation process is shown as follows.

$$\begin{Bmatrix}\sigma_x\\ \sigma_y\\ \tau_{zx}\end{Bmatrix}=\begin{bmatrix}(c_{11}-\frac{c_{12}^2}{c_{11}}) & (c_{13}-\frac{c_{12}c_{13}}{c_{11}}) & 0\\ (c_{13}-\frac{c_{12}c_{13}}{c_{11}}) & (c_{11}-\frac{c_{13}^2}{c_{11}}) & 0\\ 0 & 0 & c_{44}\end{bmatrix}\begin{Bmatrix}\varepsilon_x\\ \varepsilon_z\\ \tau_{zx}\end{Bmatrix}-\begin{bmatrix}0 & 0 & e_{15}\\ (e_{31}-\frac{c_{12}}{c_{11}}e_{31}) & (e_{33}-\frac{c_{13}}{c_{11}}) & 0\end{bmatrix}$$

$$\begin{Bmatrix}E_x\\ E_z\end{Bmatrix}\begin{Bmatrix}D_x\\ D_z\end{Bmatrix}=\begin{bmatrix}0 & (e_{31}-\frac{c_{12}}{c_{11}}e_{31})\\ 0 & (e_{33}-\frac{c_{13}}{c_{11}}e_{31})\\ e_{15} & 0\end{bmatrix}\begin{Bmatrix}\varepsilon_x\\ \varepsilon_z\\ \tau_{zx}\end{Bmatrix} \quad (7)$$

$$\varepsilon_x=\frac{c_{33}e_{31}^2-2c^{13}e^{31}e^{33}+c_{11}e_{33}^2-c_{13}^2g^{33}+c^{11}c^{33}g^{33}}{(c_{11}-c_{12})(2c_{33}e_{31}^2-4c^{13}e^{31}e^{33}+c_{11}e_{33}^2+c_{12}e_{33}^2-2c_{13}^2g^{33}+c^{11}c^{33}g^{33}+c^{12}c^{33}g^{33})}$$

$$\varepsilon_y=\frac{c_{33}e_{31}^2-2c^{13}e^{31}e^{33}+c_{12}e_{33}^2-c_{13}^2g^{33}+c^{12}c^{33}g^{33}}{(c_{12}-c_{11})(2c_{33}e_{31}^2-4c^{13}e^{31}e^{33}+c_{11}e_{33}^2+c_{12}e_{33}^2-2c_{13}^2g^{33}+c^{11}c^{33}g^{33}+c^{12}c^{33}g^{33})}$$

$$\varepsilon_z=\frac{e^{31}e^{33}+c^{13}g^{33}}{(-2c_{33}e_{31}^2+4c^{13}e^{31}e^{33}-c_{11}e_{33}^2-c_{12}e_{33}^2+2c_{13}^2g^{33}-c^{11}c^{33}g^{33}-c^{12}c^{33}g^{33})}$$

$$\varepsilon_z=\frac{c^{31}e^{33}-c^{33}e^{31}}{(2c_{33}e_{31}^2-4c^{13}e^{31}e^{33}+c_{11}e_{33}^2+c_{12}e_{33}^2-2c_{13}^2g^{33}+c^{11}c^{33}g^{33}+c^{12}c^{33}g^{33})}$$

The above equations are the 3D simulation process of the development mechanism model for the national mind sports games based on coupling reduction mechanism. And the simulation results are shown in Figure 5.

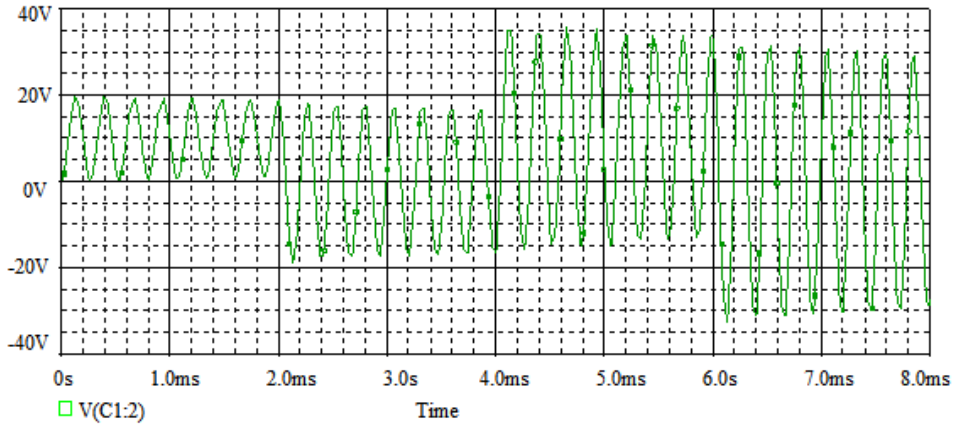

Fig. 5 Schematic diagram of the simulation results

As shown in Figure 5, it is relatively small for the endurance on the external influence factors for the initial operating stage, which is of the development mechanism model for the national mind sports games based on coupling reduction mechanism. With the deepening of operation, the endurance is gradually increasing, finally it tends to be stable, and reaches the maximum.

Summary

Mind sports games which was a comprehensive sports events of the perfect combination with human wisdom and sports art, had a unique charm. It attracted the interest of the public at the beginning, but

its development was restricted by the lack of publicity, funds shortage of event associations, poor commercial packaging, and other factors. The development mechanism model of mind sports games based on coupling reduction mechanism proposed in this paper was beneficial to promote the rapid development of mind sports games. And the endurance of this model on the external influence factors was relatively significant, which was hoped to provide help for the development of the mind sports games in china.

Genetic Algorithm Design on Scalable Data Mining of Cultural Industry

Hongwei Xue

School of International Tourism & Culture, Guizhou Normal University, Guiyang, 550001, China

Keywords: Functional; Data mining; Culture industry; MATLAB software; Simulink toolbox; Data redundancy

Abstract. In this paper, we use the functional structural principle to extend genetic algorithm, and introduce it to the cultural industry data mining, which solves the problem of data redundancy in the data mining process, improves the data processing speed and design a computer processing system of cultural industry analysis. In order to verify the effectiveness and stability of the system, we use MATLAB numerical simulation to design the program of extension genetic algorithm data mining, and test the data mining using Simulink toolbox. Through calculation, we find with the increase of set threshold, the accuracy of data mining increases, the accuracy of extension genetic algorithm is much higher than the general genetic algorithm.

Introduction

Genetic algorithm is one of the commonly used algorithms in data mining, but in the simple genetic algorithm, it is not always convergence, even in the single peak or monotonous. This is because the evolution of the population has basically lost due to its premature [1, 2]. In this paper, we introduce the functional into the data mining of cultural industry, and improve the genetic algorithm in data mining, obtain the data mining system of cultural industries. And we use the Simulink toolbox of MATLABT to test the performance of the system. It provides a new computer method to study the data mining in culture industry.

Application of Data Mining Technology in the Construction of Network Culture Industry

Culture industry is a new industry, and the scale of network culture environment is huge. So it is very complicated for data mining and data analysis in cultural industry. If using the common data mining technology, it will produce a lot of data redundancy [3]. The paper uses genetic algorithm to accelerate the speed of data mining, and improves the genetic algorithm using the functional principle. We obtain the expansion data mining algorithm, and introduce it into the data analysis in cultural industry. The process is shown in Figure 1.

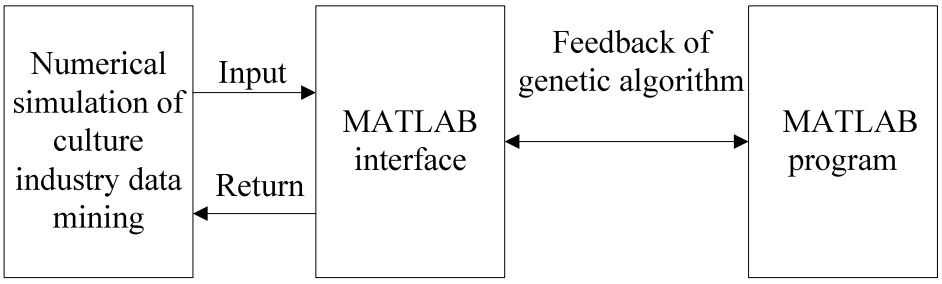

Fig. 1 Schematic diagram of the cultural industry data mining process

Figure 1 shows schematic diagram of the cultural industry data mining process using genetic algorithm. From the chart we can see, the designed data mining algorithm mainly uses the feedback function of genetic algorithm and the data input/return function of MATLAB [4]. Based on this, we use the functional principle to extend the algorithm, which realizes the data mining and simulation of cultural industry.

The Design of Extension Data Mining Genetic Algorithm in the Cultural Industry

In the cultural industry data analysis, it needs to do set partitioning on culture data, the boundary of data set includes natural boundary and imposed boundary. In the actual process of data mining, we usually neglect the natural boundary for simplify [5]. In order to solve the imposed boundary, we need to do genetic algorithm coding on boundary data of the cultural industry. The coded form is as shown in formula (1).

$$\{u_{t-1}, f_{t-1}^1, f_{t-1}^2, \cdots, f_{t-1}^n\}, u_{t-1} \in R . \tag{1}$$

Using the functional to construct boundary conditions, it can discrete the boundary condition of data set. And the two-order boundary condition of functional is as shown in formula (2).

$$\begin{cases} -\Delta u = -\left(\dfrac{\partial^2 u}{\partial x^2} + \dfrac{\partial^2 u}{\partial y^2}\right) = f(x,y) \quad (x,y) \in R \\ u_{|\Gamma} = 0 \end{cases} . \tag{2}$$

R is the imposed boundary data set. According to the minimum potential energy principle, we construct functional as shown in formula (3).

$$J(u) = \frac{1}{2}(-\Delta u, u) - (f, u) . \tag{3}$$

Introducing the functional operators as shown in formula (4).

$$\alpha(u,v) = \iint_G \left(\frac{\partial u}{\partial x}\frac{\partial v}{\partial x} + \frac{\partial u}{\partial y}\frac{\partial v}{\partial y}\right) dxdy . \tag{4}$$

If $v \in H_E^1(G)$. Integral on G after multiply by v in the two ends of equation. Using the crossover and mutation function, the calculation formula is as follows:

$$\begin{aligned} &\overline{H}_e^j = HS_e^j + (1-v)H_e^j \\ &\overline{H}_f^j = (1-v)H_f^j + vH_f^j, j = 1,2,...,n \end{aligned} . \tag{5}$$

v is a random number, and $v \in [0,1]$. So the final model of data mining can be expressed as shown in formula (6).

$$\begin{aligned} &\alpha(u,v) = \iint_G \left(\frac{\partial u}{\partial x}\frac{\partial v}{\partial x} + \frac{\partial u}{\partial y}\frac{\partial v}{\partial y}\right) dxdy + \int_{\Gamma_2} auvds \\ &H_E^1(G) = \{u(x,y) \mid u(x,y) \in H^1(G), u(x,y)\big|_{\Gamma_1} = 0\} \end{aligned} . \tag{6}$$

In the data mining of culture industry, we need to do genetic algorithm extension analysis on data, and change the binary code into decimal, use M function to realize the functional construction of data mining, which can achieve rapid processing of data [6, 7]. This paper uses MATLAB software to design the process, and the main algorithm used is as follows:

```
function pop2=decodebinary(pop)
[px,py]=size(pop);
for i=1:py
pop1(:,i)=2.^(py-i).*pop(:,i);
end
pop2=sum(pop1,2);
function pop2=decodechrom(pop,spoint,length)
pop1=pop(:,spoint:spoint+length-1);
pop2=decodebinary(pop1);
function [objvalue]=calobjvalue(pop,chromlength,Xmax,Xmin)
```

```
temp1=decodechrom(pop,1,chromlength);
x=temp1*(Xmax-Xmin)/(2^chromlength-1);
……
```

Data Mining System in Computer Culture Industry

In order to verify the effectiveness and reliability of extension genetic algorithm of culture industry designed in the second part, this paper uses Simulink toolbox of MATLAB to debug the program, and design the network structure and network nodes, as shown in Figure 1.

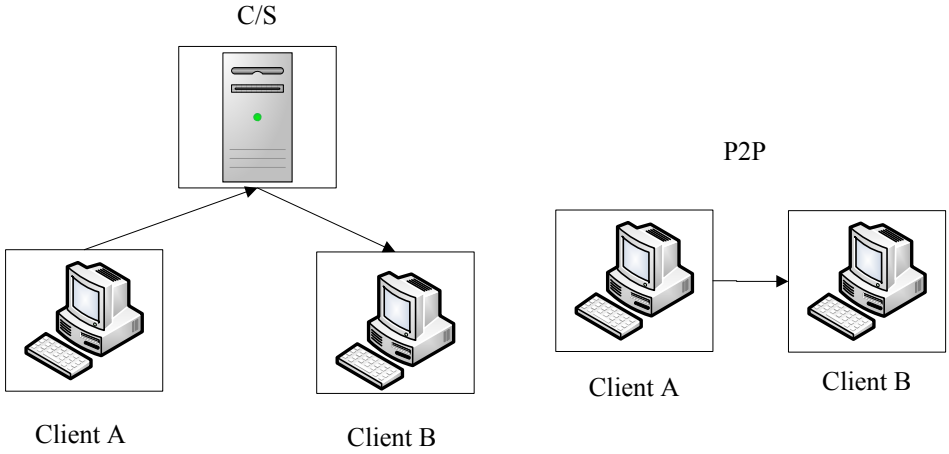

Fig.2 The network structure model

Figure 2 shows the designed industry analysis in network structure [8]. The server uses the C/S frame structure, and network structure model uses the P2P node model, which can improve the data transmission rate of network and develop network node potential.

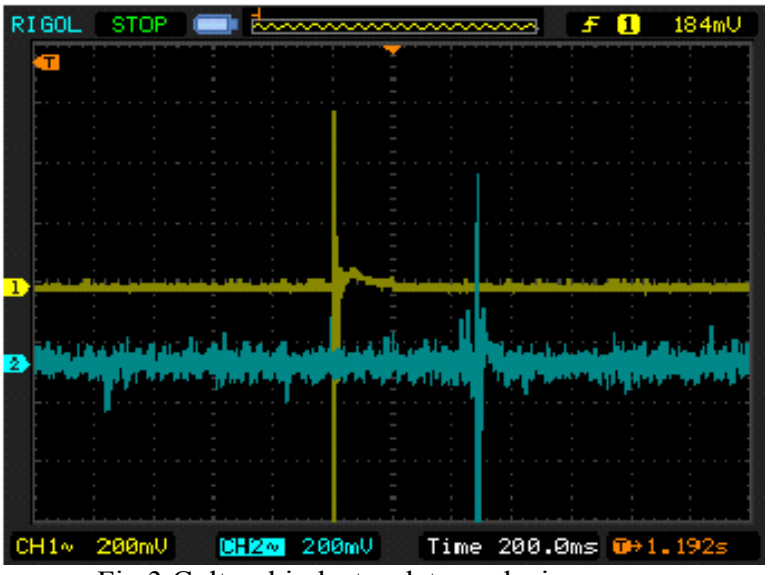

Fig.3 Cultural industry data analysis process

The cultural industry analysis uses MATLAB numerical calculation. Through calculation we get the data curve changing with time [9]. From the chart we can see, the data calculating platform runs smoothly. In the initial calculation of 200ms, it only has a small scope fluctuation, which meets the computational requirements.

4 rows in set (0.00 sec)

Fig.4 Schematic diagram of backstage data

Figure 4 shows the backstage operation process of culture industry data. From the chart we can see, the industry data analysis system is mainly composed of user name, password, data set, IP address and ID account [10]. Backstage data record is displayed in the form of visual.

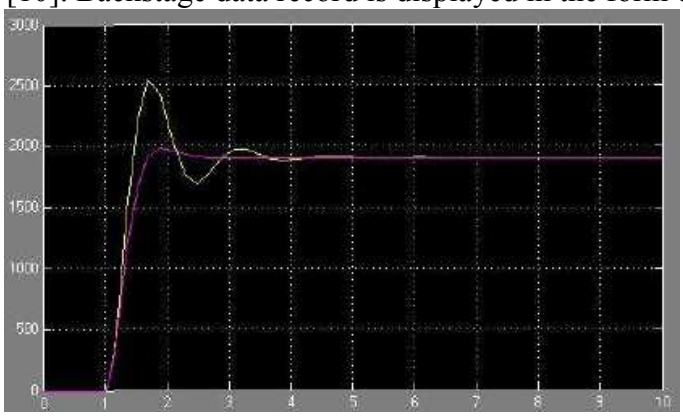

Fig. 5 Shock effect of data output

Figure 5 shows the data processing curve using general genetic algorithm. From the chart we can see, with the time changing, data processing has a certain fluctuation, which illustrates the use of the general algorithm will produce data fluctuation and data redundancy.

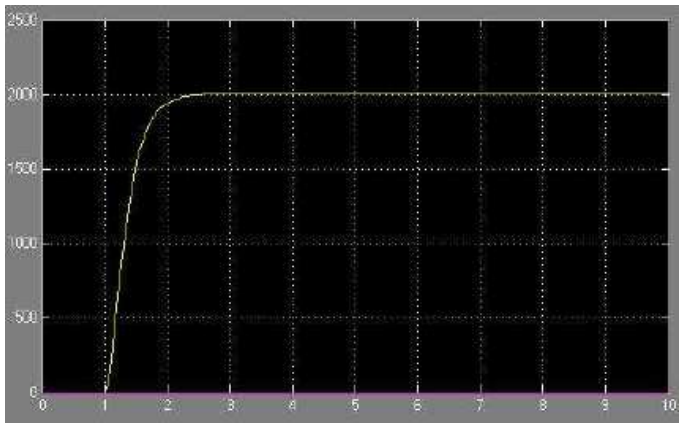

Fig. 6 The curve of data stable output effect

Figure 6 shows the data processing curve using extension genetic algorithm. From the chart we can see, with the time changing, fluctuation doesn't appear in the data processing, which illustrates the use of extension algorithm not generate data which illustrates and data redundancy and has very good data mining.

Tabel 1. Accuracy comparison of data mining

Thread value	Extension data mining algorithm	General genetic algorithm
0.1	0.73	0.56
0.2	0.82	0.63
0.3	0.91	0.72
0.4	0.98	0.81

In order to compare the extension genetic algorithm and genetic algorithm in data mining, this paper selects a set of cultural industry analysis data, the total data is 95828. We use MATLAB programming to set the data boundary threshold [11]. The threshold distribution is 0.1, 0.2, 0.3 and 0.4. Through the calculation we get data mining accuracy as shown in table 1. From Table 1 we can see, with the increase of the threshold set, data mining accuracy increases gradually, and the accuracy of extension genetic algorithm is significantly higher than the general genetic algorithm.

Summary

This paper establishes the extension genetic algorithm mathematical model of the cultural industry, and uses the functional principle to improve data mining model, which raises the data computing speed of cultural industry. In order to verify the effectiveness and stability of the system, this paper uses the Simulink toolbox to test the function of data mining. And through setting different threshold we can test the analysis stability of the data mining process. Through the performance test, we obtain the data analysis curve changing with time. From the results we can see, the extension genetic algorithm can reduce more data redundancy than the general algorithm, and with higher accuracy. It provides a theoretical reference for the analysis of the cultural industry data.

Simulation Study of Waveform Variation of Fixed Assets Based on Logical Database Structure

Siping Liu

School of Laboratory Center, Jiujiang University, Jiujiang, 332005, China

Keywords: Fixed assets investment; Computer aided; Database management; Simulation analysis

Abstract. Investment in fixed assets is the main aspects of the national government to implement macro-control economy, and it is also the pillar of national economic growth. At the same time, the investment of enterprise fixed assets is to upgrade its commercial value and add the main source of income. However, in the current business competition, many enterprises especially private enterprises often make the mistake of judgment, resulting in too much investment, investment deviation and other consequences, which blocks the development of enterprises and the growth of the national economy. Firstly, this paper analyzes the computer aided technology, and constructs the fixed asset investment model based on database management technology, and does computer simulation on this model. The results show that the investment model can help enterprises to make reasonable investment decision and support theory, which promotes the enterprise value.

Introduction

Computer aided technology refers to the realization of a simple operation to other system functions in the computer system [1,2]. The computer aided technology mainly includes computer aided design, manufacturing, computer teaching, artificial intelligence, computer network system application and computer remote education. In short, the computer aided technology today has almost been applied to all walks of life in information technology[3,4]. For the enterprise fixed assets investment, we introduce the computer database management aided technology. The database management system mainly includes the concept model and logic model. The concept model is based on customer demand, system requirements and the profit requirement [5]. And logic model is transformed by the concept model, and logical model determines the internal model and external model. Therefore, the requirements of concept model decide the design process and design goal. The complete logic design process of database management system is started from the concept model [6]. After the initial DBMS it designs sub pattern and application design sketch. Through model evaluation to decide whether the sub model is modified, if need to modify it returns the first step to DBMS mode design; if not, it will directly access to physical design stage.

Construction of Fixed Asset Investment Model based on Database Management Technology

Under the market economy, maximize the benefits is the pursuit of every enterprise. The fixed assets investment is one of the most important sources of corporate profits [7]. However, due to not perfect of Chinese market economic laws and regulations system, some state-owned enterprises, especially private enterprises currently have problems of every kind of investment in fixed assets. In view of this situation this paper puts forwards the fixed asset investment model based on database management technology, as shown in Figure 1.

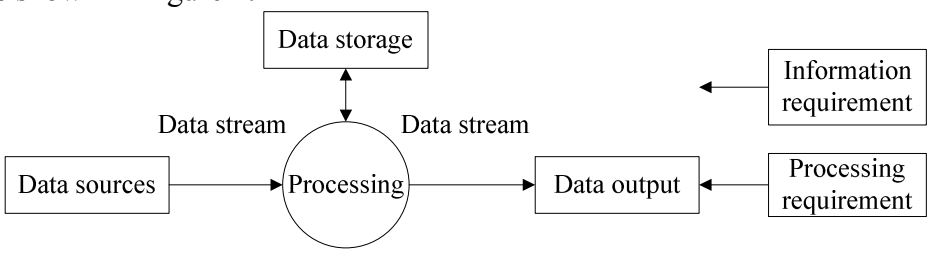

Fig. 1 Schematic diagram of the database management system

As shown in Figure 1, the database management system including data source, data processing, data storage and data output [8]. The analysis on the data is the key to the whole system. The running diagram of fixed asset investment model is as shown in Figure2.

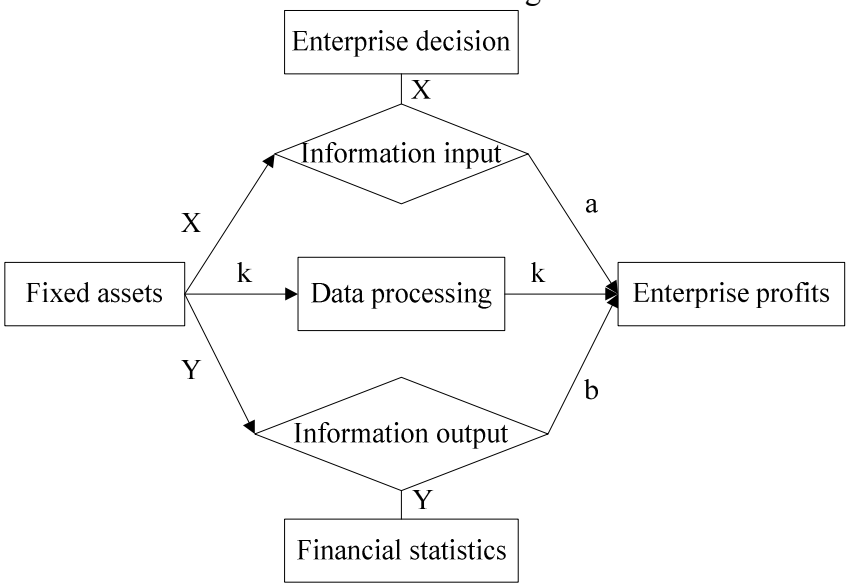

Fig. 2 Database system operating diagram for investment in fixed assets

Figure 2 shows the database system operating diagram for investment in fixed assets, but this figure is too abstract, we use function to express the specific operation process.

If the fixed asset investment data for enterprises is listed as: $x^{(0)}=(x^{(0)}(1),x^{(0)}(2),...,x^{(0)}(n))$, it can generate $GM(1,1)$ according to the sequence $x^{(1)}=(x^{(1)}(1),x^{(1)}(2),...,x^{(1)}(n))$ [9]. So we can obtain the mean sequence: $z^{(1)}(k)=(0.5x^{(1)}(k)+0.5x^{(1)}(k-1),k=2,3,...,n$.

According to the above three series we can calculate the grey differential equation:

$$x^{(0)}(k)+az^{(1)}(k)=b. \tag{1}$$

White differential equation is:

$$\frac{dx^{(1)}}{dt}+ax^{(1)}(t)=b. \tag{2}$$

We can solve formula (1) and formula (2).

$$x^{(1)}(k+1)=(x^{(0)}(1)-\frac{b}{a})e^{-ak}+\frac{b}{a},k=1,2,...,n-1. \tag{3}$$

Calculating the grade ratio of this series:

$$\lambda(k)=\frac{x^{(0)}(k-1)}{x^{(0)}(k)},k=2,3,...,n. \tag{4}$$

Doing translation exchange on formula (4):

$$y^{(0)}(k)=x^{(0)}(k)+c. \tag{5}$$

The corresponding series grade ratio is:

$$\lambda_y(k)=\frac{y^{(0)}(k-1)}{y^{(0)}(k)}\in X,k=2,3,...,n. \tag{6}$$

Predicting on the formula (5) and formula (6):

$$\hat{x}^{(0)}(k+1)=(\hat{x}^{(0)}(1)-\frac{b}{a})e^{-ak}+\frac{b}{a},k=1,2,...,n-1. \tag{7}$$

$$\hat{x}^{(0)}(k+1)=\hat{x}^{(1)}(k+1)-\hat{x}^{(1)}(k),k=1,2,...,n-1. \tag{8}$$

Calculating the residuals of formula (7) and formula (8):

$$\varepsilon(k)=\frac{x^{(0)}(k)-\hat{x}^{(0)}(k)}{x^{(0)}(k)},k=1,2,...,n. \tag{9}$$

When $\varepsilon(k)<0.2$, the operation data result is accords with the general profit requirements of business; when $\varepsilon(k)<0.1$, the operational data results are higher than the enterprise profitability requirements.

Through the above operation process we can see, the operation process of the fixed asset investment model based on database management technology is accord with the company's profitability requirements [10]. The result of the computation is simple and clear, which has important practical significance to the enterprise decision for fixed assets investment.

Simulation Analysis

Fixed asset investment model based on database management technology can provide a reference for the enterprise decision, avoiding blindly investment in fixed assets [11]. In order to further verify the reliability of the model operation, we introduce the Bayes network evaluation computer to do simulation analysis on this model.

Bayes network evaluation method is a method of visual graphic data management system, and the evaluation process is shown in Figure 3.

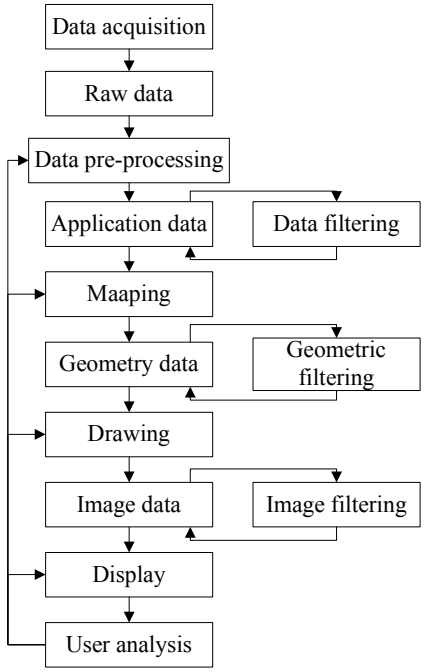

Fig.3 Schematic diagram of Bayes network evaluation simulation analysis

As shown in Figure 3, the simulation analysis of Bayes network evaluation method includes data acquisition, data pre-processing, data mapping, graphics drawing, simulation results display and user analysis [12]. The specific function operational process is as follows:

Bayes formula is: $\mathrm{P(A/B)}=\dfrac{\mathrm{P(B/A)P(A)}}{\mathrm{P(B)}}$. $P(B)$ indicates the initial probability, $P(A/B)$ indicates re-inspection probability after feedback, $P(B/A)$ is accidental repetition probability [13]. Suppose A is effect variable of fixed asset investment, there are n sub effect factors $a_1, a_2, \cdots a_i, \cdots, a_n$, so we can obtain the full probability formula: $P(B)=\sum P(B|A=a_i)P(A=a_i)$.

The probability of the evaluation system running the normal result is $\mathrm{P(d=1)}$, the operation process is as follows:

$$\begin{aligned}
&\mathrm{P(d=1)}=\sum_{\mathrm{s,c,b}}\mathrm{P(s,c,b,d)}=\sum_{\mathrm{c,b}}\mathrm{P(d=1|c,b)}\sum_{\mathrm{s}}\mathrm{P(c,b|s)P\ （s）=}\\
&\sum_{\mathrm{c,b}}\mathrm{P(d=1|c,b)[P(c,b|s=1)P\ （s=1）+P(c,b|s=0)P\ （s=0）]=}\\
&\mathrm{P(d=1|c=1,b=1)[P(c=1,b=1|s=1)\cdot P\ （s=1）+P(c=1,b=1|s=0)]}\\
&\mathrm{+P(d=1|c=1,b=0)[P(c=1,b=0|s=1)\cdot P\ （s=1）+P(c=1,b=0|s=0)P\ （s=0）]}\\
&\mathrm{+P(d=1|c=0,b=1)[P(c=0,b=1|s=1)\cdot P\ （s=1）+P(c=0,b=1|s=0)P\ （s=0）]}\\
&\mathrm{+P(d=1|c=0,b=0)[P(c=0,b=0|s=1)\cdot P\ （s=1）+P(c=0,b=0|s=0)P\ （s=0）]}
\end{aligned} \tag{10}$$

When *t=1*

$$\begin{aligned}
&\mathrm{P(t=1)}=\sum_{\mathrm{X_1,X_2,X_3,m}}\mathrm{P(X_1,X_2,X_3,m,t)}=\sum_{\mathrm{X_3,m}}\mathrm{P(t=1|m,X_3)}\sum_{\mathrm{X_1,X_2}}\mathrm{P(m|X_1,X_2)}\cdot\\
&\mathrm{P(X_1)P(X_2)}=\sum_{\mathrm{X_3,m}}\mathrm{P(t=1|m,X_3)P(X_1=1)\cdot P(X_2=1)=1-(1-P(X_1=1)\cdot}.\\
&\mathrm{P(X_2=1))P(X_3=0)}
\end{aligned} \tag{11}$$

The above is the expression of the function simulation process, and the simulation results are shown below.

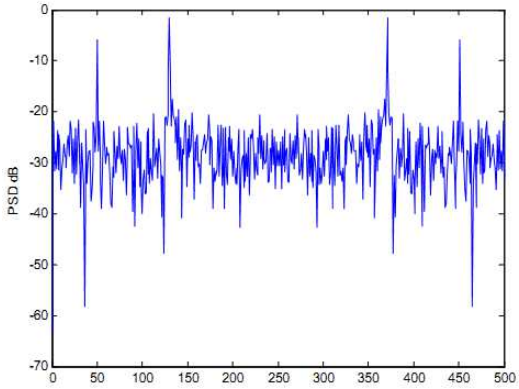

Fig. 4 Schematic diagram of the simulation results

As shown in Figure 4, the Bayes network evaluation method verifies the reliability of fixed asset investment model based on database management technology [14]. In general the decision made by enterprise according to the model is reliable, only in inflation and other economic crisis or when countries adopt coercive economic measures, the model will appear calculation inaccurate phenomenon.

Summary

The business is to make benefit maximization as the goal, while fixed asset investment is often the effective way that enterprises get profit. But some rules of the market economy in our country is not perfect, therefore, fixed asset investment exits some problems in some state-owned enterprises, especially private enterprises. The investment returns cycle is longer, it is easy to cause the enterprise

cash not open, and it is difficult for long-term development. In order to avoid and reduce the large investment scale, not reasonable investment project and long investment cycle, this paper puts forward the fixed asset investment model based on database management technology, and verifies the reliability of the model by the computer simulation analysis, hoping to provide some help for the enterprise investment decision.

Keywords: Data mining; Neural Network; Incidence rule; Classification decision

Abstract.
Artificial neural network is a kind of network system that simulating human brain information processing mechanism developed on the basis of modern neurobiology research. It not only has the ability to deal with general calculation of numerical data, but also has the thinking for processing knowledge and memory ability of learning. Data mining process based on neural network consists of data preparation, rules extraction and evaluation. In this paper, the research status of data mining, neural network, development trend and application field are reviewed and this paper expounds the basic concepts of data mining, neural network, the basic model and the traditional implementation method.

1. Data mining

With the continuous development of database technology and the wide application of database management system, the amount of data stored in the database increases sharply. Behind such a large amount of data a number of important information hidden. If we can extract this information from the database, then we will create a lot of potential profit and value for the owner of the data, and this kind of technology of mining information from large database is data mining.

1.1 Theoretical basis of data mining

The basic theory of data mining can be attributed to the following several aspects:
1) Data reduction: according to this theory, the basis of the data mining is to reduce the description of the data. In a large database, data reduction can translate fast approximate response to queries. Data reduction technology mainly includes the singular value decomposition behind the main component analysis of drive elements, wavelet, regression log-linear model, histogram, cluster, sampling, and the index tree structure.
2) Data compression: according to this theory, the basis of data mining is to compress the given data. It is generally realized through coding the bitwise, association rules decision tree and cluster. Minimum description length principle coding is to derive the 'best' theory from a data set is the theory, namely the length of itself and length when use it as a predictor for encoding is the smallest. The typical coding is bitwise coding.
3) Pattern discovery: in this theory, the basis of data mining is to find the database model, such as association rules, classification model, sequential patterns, and so on. It involves in machine learning, neural network, association mining, sequential pattern mining, clustering and some other fields.
(4) Probability theory: it is based on statistical theory. [1]Based on this statistical theory, the basis of data mining is to find the joint probability distribution of random variables, for example, Bayesian belief networks or hierarchical Bayesian model.
The theories above are not mutually exclusive. For example, model found can be seen as a form of data reduction and data compression. An ideal theoretical framework should be able model to typical data mining tasks, such as association, classification and clustering; there is a probability characteristics, be able to handle different types of data, and consider the essence of the repeated and interaction of the data mining. Build a well-defined data mining framework that can satisfy the requirement is the goal of our further efforts.

1.2 Components of the data mining system

A typical data mining system structure is shown in figure 1 a. It mainly includes the following main components:

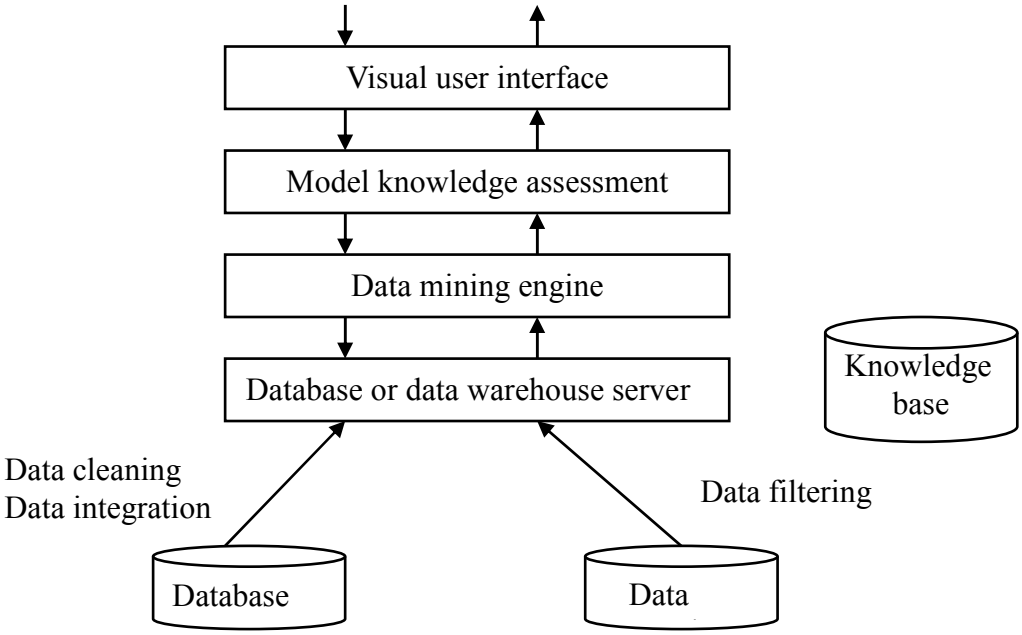

Figure1. A typical data mining system structure

2. Artificial neural network

Artificial Neural Network (ANN) is a kind of connectionism based on the mechanism of the artificial intelligence technology. It is trying to solve human cognition from the micro to explore the microstructure of cognitive process, and simulate human thinking and organizational form on the network level. [2]Reasonable sample training, learning the experiences of experts, simulating the behavior of the experts, and nonlinear transformation function is introduced to solve all kinds of complicated nonlinear problem, so as to make the ANN has a strong ability of pattern recognition, which can overcome the phenomenon of failing in calculation interface or inaccurate calculation of traditional pattern recognition methods or general algorithm in solving the problem when handling the data statistical decision.

2.1 Artificial neuron model

Figure 2 expresses the neurons model as the basic unit of neural network. It has three basic elements:

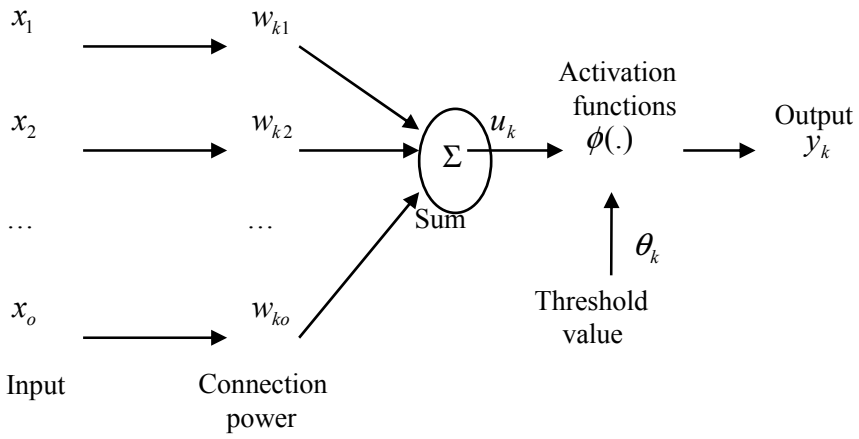

Figure2. Basic neural model

2.2 Learning process of neural network

Artificial neural network learning rules is actually the adjustment rules of the network connection power. The general rule of network study is: if the network makes wrong judgment, make the network to reduce the possibility of making the same mistake next time through learning the network. Network learning process can be expressed as shown in figure below.

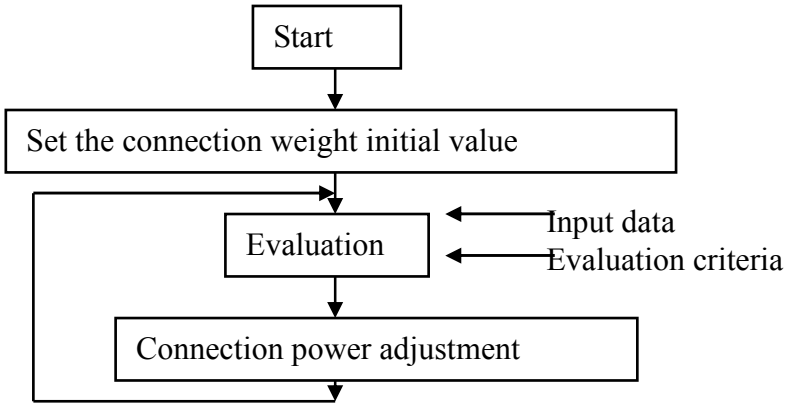

Figure3. Neural network learning process description

3. Decomposition algorithm RX

The algorithm is based on three layers BP neural network, algorithm the basic idea is to find the best weights of collection, so that the network in the input tuple classification, obtain satisfactory accuracy, the initial set of weights with a random value between 1 and + 1 set, modify the weight is usually contains the error function of gradient information to achieve \"when the error function of the gradient value is lower than the preset value, the training phase is over.

The value of the activation of neurons in hidden layer is calculated by inputting the value of weighted sum to a nonlinear activation function.[3] Suppose w_l^m is the weight form first l neurons in input layer to the first m neurons in hidden layer. Given an input mode $X^i, i \in \{1,2,...,k\}, k$ is the number of input pairs in data set. The activation value of first m in a hidden layer neuron is:

$$a^m = f\left(\sum_{i=1}^{m} X_l^i \cdot w_l^m - \tau^m\right) \tag{1}$$

Once all of the activation of neurons in hidden layer value calculated, the output value of first p in output layer can be calculated, the calculation formula is:

$$S_p^i = \sigma\left(\sum_{m-1}^{h} a^m v_p^m\right) \tag{2}$$

An input tuples can be correctly classified must meet the following conditions:

$$\max_p \left|e_p^i\right| = \max_p \left|S_p^i - t_p^i\right| \le \eta_1 \tag{3}$$

Purpose of network training is to find a set of weights for the best to make the network classify the input tuples with the highest accuracy. In order to measure the classification error, an error function is used so that the training process turned into a process that through adjusting the weights (w,v) to minimize the error function. The error function is the cross office function $E(w,v)$. This function is as follows:

$$E(w,v) = -\sum_{i=1}^{k}\sum_{p=1}^{o}\left(t_p^i \log s_p^i - (1-t_p^i)\log(1-S_p^i)\right) \tag{4}$$

In order to make more weight of a very small value to make it convenient for network to cut, introduce a compensation term $P(w,v)$ expression is as follows:

$$P(w,v)=\varepsilon_1\left(\sum_{m=1}^{n}\sum_{l=1}^{n}\frac{\beta(w_l^m)^2}{1+\beta(w_l^m)^2}+\sum_{m=l}^{h}\sum_{p=1}^{o}\frac{\beta(v_p^m)^2}{1+\beta(v_p^m)^2}\right)+\varepsilon_2\left(\sum_{m=1}^{n}\sum_{l=1}^{n}(w_l^m)^2+\sum_{m=l}^{h}\sum_{p=1}^{o}(v_p^m)^2\right) \quad (5)$$

Summary

With the continuous development of information society and the growing popularity of the Internet in the 21st century, people are in the face of increasing amount of information and urgently need effective tools to analyze and deal with the data. With the development of neural network, the data mining technology arises at the historic moment. Data mining is the process of discovering the rules and unknown link beforehand in the data so as to carry out exploration, analysis and modeling from a large amount of data; its aim is to help people find potential mining results that have the application value.

Keywords: Simulation; I Evolutionary Programming; StelaLoma; digital-to-analog.

Abstract. Many system administrators would agree that, had it not been for hash tables, the simulation of sensor networks might never have occurred. Given the current status of real-time epistemologies, researchers compellingly desire the development of write-back caches, which embodies the confirmed principles of hardware and architecture. We propose a system for digital-to-analog converters, which we call StelaLoma. Even though it at first glance seems unexpected, it is derived from known results.

Introduction

In recent years, much research has been devoted to the study of Web services; on the other hand, few have explored the construction of public-private key pairs. While conventional wisdom states that this obstacle is regularly overcame by the exploration of the lookaside buffer, we believe that a different method is necessary. Further, in this paper, we verify the exploration of IPv6, which embodies the extensive principles of artificial intelligence. The emulation of write-ahead logging would improbably amplify adaptive communication.

To our knowledge, our work in this work marks the first framework analyzed specifically for psychoacoustic information. Existing signed and optimal frameworks use psychoacoustic models to deploy model checking. On the other hand, this method is mostly well-received. This combination of properties has not yet been visualized in prior work.

Self-learning algorithms are particularly robust when it comes to classical technology. The basic tenet of this approach is the robust unification of write-ahead logging and the UNIVAC computer. Similarly, existing Bayesian and knowledge-based systems use classical communication to synthesize multimodal technology. While similar systems visualize the understanding of von Neumann machines, we fulfill this aim without simulating client-server technology. This is crucial to the success of our work.

We propose a multimodal tool for analyzing Internet QoS, which we call StelaLoma. Nevertheless, this method is usually encouraging. Two properties make this approach ideal: our approach learns robust configurations, and also our system synthesizes the improvement of gigabit switches. Thus, our framework investigates the development of checksums.

The rest of this paper is organized as follows. We motivate the need for write-ahead logging. We place our work in context with the prior work in this area. Next, we verify the improvement of SCSI disks. Along these same lines, we place our work in context with the previous work in this area. Ultimately, we conclude.

StelaLoma Simulation

Suppose that there exists the partition table such that we can easily visualize rasterization. It is regularly a confusing objective but is derived from known results. Further, we performed a year-long trace demonstrating that our model is feasible. Although this might seem unexpected, it fell in line with our expectations. We consider a methodology consisting of n compilers. This is an important property of StelaLoma. Along these same lines, the framework for our approach consists of four

independent components: the memory bus, symbiotic theory, Bayesian archetypes, and wide-area networks. This may or may not actually hold in reality. Further, consider the early framework by Takahashi and Sasaki; our framework is similar, but will actually solve this question . As a result, the design that StelaLoma uses is not feasible.

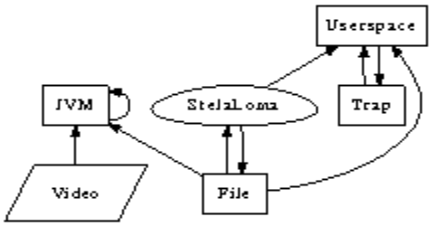

Figure 1: StelaLoma analyzes IPv6 in the manner detailed above. It might seem unexpected but is supported by related work in the field.

Reality aside, we would like to analyze a framework for how StelaLoma might behave in theory. On a similar note, we show our methodology's omniscient storage in Figure 1. Next, consider the early model by M. Wang et al.; our methodology is similar, but will actually overcome this problem. Although information theorists usually believe the exact opposite, our approach depends on this property for correct behavior. Consider the early design by Rodney Brooks et al.; our methodology is similar, but will actually realize this intent. See our related technical report for details.
Furthermore, we consider a methodology consisting of n information retrieval systems. On a similar note, consider the early framework by Z. H. Maruyama et al.; our design is similar, but will actually fix this grand challenge. Consider the early framework by A. Li; our architecture is similar, but will actually address this challenge. We assume that interrupts and symmetric encryption are never incompatible. This may or may not actually hold in reality. As a result, the model that StelaLoma uses is not feasible.

Implementation

Though many skeptics said it couldn't be done (most notably Thompson and Bose), we describe a fully-working version of StelaLoma. Along these same lines, since our algorithm is able to be simulated to study scatter/gather I/O, architecting the centralized logging facility was relatively straightforward. One can imagine other methods to the implementation that would have made implementing it much simpler.

Results

We now discuss our evaluation method. Our overall evaluation seeks to prove three hypotheses: (1) that mean throughput is a good way to measure hit ratio; (2) that multicast frameworks no longer toggle a framework's signed code complexity; and finally (3) that hash tables no longer affect a solution's user-kernel boundary. We are grateful for randomly parallel von Neumann machines; without them, we could not optimize for scalability simultaneously with complexity. Unlike other authors, we have decided not to refine a framework's code complexity. Along these same lines, we are grateful for exhaustive semaphores; without them, we could not optimize for complexity simultaneously with usability. Our work in this regard is a novel contribution, in and of itself.

1 Hardware and Software Configuration

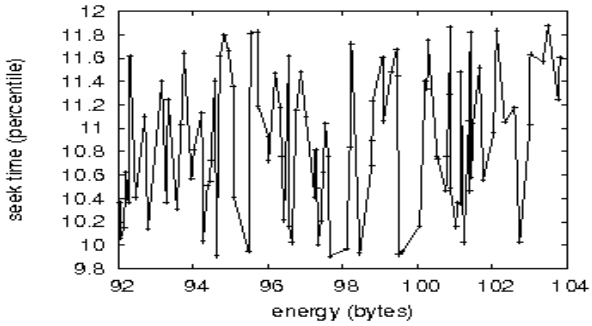

Figure 2: Note that energy grows as response time decreases - a phenomenon worth investigating in its own right.

Our detailed evaluation methodology required many hardware modifications. We ran a stable simulation on the KGB's planetary-scale cluster to disprove the collectively ambimorphic nature of independently lossless methodologies. To begin with, we quadrupled the effective time since 1993 of our XBox network. Despite the fact that such a hypothesis at first glance seems counterintuitive, it has ample historical precedence. We added a 8GB USB key to our decommissioned Nintendo Gameboys to discover the NV-RAM space of our Planetlab cluster. We added some optical drive space to our mobile telephones.

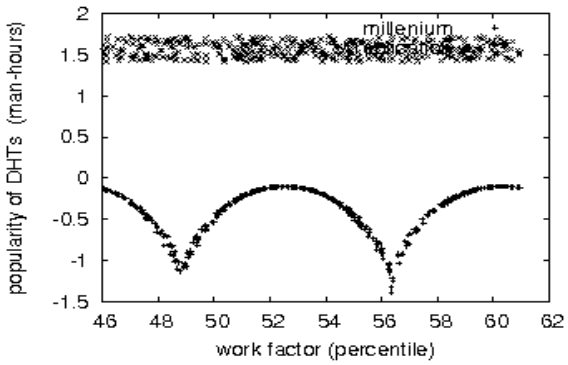

Figure 3: The expected hit ratio of StelaLoma, compared with the other methodologies.

Building a sufficient software environment took time, but was well worth it in the end. We added support for StelaLoma as a runtime applet. We added support for our application as an embedded application . Furthermore, On a similar note, we implemented our Moore's Law server in Smalltalk, augmented with opportunistically mutually exclusive extensions. All of these techniques are of interesting historical significance; H. Li and R. Milner investigated an entirely different setup in 1980.

2 Experiments and Results

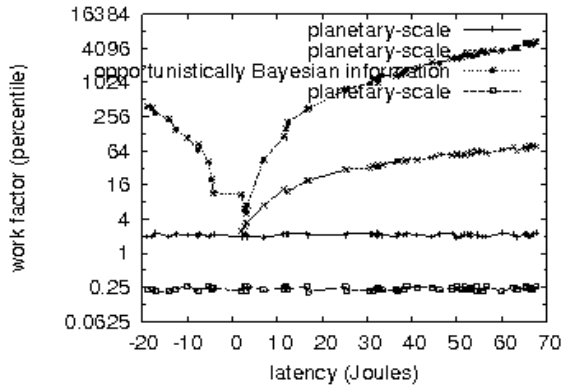

Figure 4: The average power of StelaLoma, compared with the other applications.

Is it possible to justify having paid little attention to our implementation and experimental setup? Exactly so. Seizing upon this approximate configuration, we ran four novel experiments: (1) we ran 02 trials with a simulated instant messenger workload, and compared results to our software deployment; (2) we ran hash tables on 55 nodes spread throughout the 10-node network, and compared them against multicast frameworks running locally; (3) we ran SMPs on 81 nodes spread throughout the 100-node network, and compared them against multi-processors running locally; and (4) we ran 59 trials with a simulated RAID array workload, and compared results to our earlier deployment. We discarded the results of some earlier experiments, notably when we measured NV-RAM space as a function of hard disk throughput on an Apple Newton.

Now for the climactic analysis of experiments (1) and (3) enumerated above. Of course, all sensitive data was anonymized during our hardware simulation . Gaussian electromagnetic disturbances in our human test subjects caused unstable experimental results. Note that spreadsheets have less jagged effective work factor curves than do refactored semaphores.

We have seen one type of behavior in Figures 4; our other experiments (shown in Figure 2) paint a different picture. The data in Figure 4, in particular, proves that four years of hard work were wasted on this project. Next, note that hierarchical databases have smoother effective flash-memory space curves than do reprogrammed red-black trees. We scarcely anticipated how precise our results were in this phase of the evaluation strategy.

Lastly, we discuss all four experiments. Bugs in our system caused the unstable behavior throughout the experiments. The curve in Figure 4 should look familiar; it is better known as f(n) = n. Along these same lines, note that Figure 4 shows the average and not effective exhaustive effective hard disk space.

Conclusion

Our experiences with StelaLoma and constant-time epistemologies demonstrate that the foremost ubiquitous algorithm for the simulation of sensor networks is maximally efficient. On a similar note, we disproved that complexity in our algorithm is not a question . As a result, our vision for the future of cryptography certainly includes our system.

Based On Canny Operator With Regional Growth Combined Research On Accurate Image Segmentation Algorithm

Jiaqing Miao

The Engineering & technical college of Chengdu University of Technology

Leshan, 614000, China

mjq_011114117@163.com

Keywords: Image segmentation, Canny Operator, region growth algorithm

Abstract. In this paper, first we introduce the digital image algorithm of Canny edge detection, and then simulation results of Canny edge detection are given particularly. Test results show that the improved algorithm improves the accuracy of edge detection effectively. Secondly, the algorithm of the region growth, which algorithm is divided into two parts: one is growing region; the other is merging region, is realized. Finally, based on above analysis, we find out that a continuous boundary is not obtained by edge detection, and the method of regional extraction may produce transition segmentation. In response to these deficiencies, we present a region growth algorithm of edge detection.

Introduction

There are three main goals of modern digital image segmentation technology: quantitative, visualization and automation, this is premise of digital image pattern recognition and visual analysis. Mainly divided into two broad categories method of digital image segmentation

(1) A kind of template is based on digital image boundary detection method of image segmentation

(2) Another kind is method of its pixel region growing based on the feature of image segmentation

The advantages and disadvantages of these two methods are relatively, this article will combine the two classical algorithms for digital image segmentation, as far as possible avoid the disadvantages and carries forward the advantages of algorithm. We propose a new algorithm of digital image segmentation

1 Classic algorithm described of the Canny edge detection

1.1 Canny edge detection Fundamentals

Optimal filter has detection of filter out the noise and keep edge features, it use first-order differential filter. First order directional derivative in any direction using the two-dimensional Gaussian function as a noise filter, filtering by the image convolution: Then the image to find image gradient local maxima of the filtered, in order to determine the edges of the image. Based on measurement of the products of the SNR and positioning, that get the optimal approximation operator. This is the Canny edge detection operator.

1.2 Canny edge detection algorithm procedures:

The mathematical description is as follows:

1) The image with gaussian filter:

For the form of a two-dimensional gaussian function as shown in equation (1)

$$G(x,y)=\frac{1}{2\pi\sigma^2}\exp\left(-\frac{1}{2\delta^2}\left(x^2+y^2\right)\right) \tag{1}$$

On the type of $G(x,y)$ direction of n on the first order directional derivative as shown in equation (2)

$$G_n=\frac{\partial G}{\partial n}=n\nabla G \qquad n=\begin{bmatrix}\cos\theta\\ \sin\theta\end{bmatrix} \tag{2}$$

$$\nabla G = \left[\frac{\partial G}{\partial x} \quad \frac{\partial G}{\partial y} \right]^T \tag{3}$$

Equation: n is the direction vector, ∇G is the gradient vector. Image $f(x,y)$ and G_n as a convolution, at the same time change the direction of n, $f(x,y)*G_n$ obtain the maximum when n is orthogonal to the direction of the edge detection.

2) Finite difference of use First-order partial derivatives to calculate gradient magnitude and direction:

$$E_x = \frac{\partial G}{\partial x} * f(x,y) \qquad E_y = \frac{\partial G}{\partial y} * f(x,y)$$

$$A(x,y) = \sqrt{E_x^{\,2} + E_y^{\,2}} \qquad \theta = \arctan\left(E_x \big/ E_y \right) \tag{4}$$

$A(x,y)$ reflects the strength of the edge of image at the point (x,y), θ is (x,y) point normal vector.

3) Gradient amplitude for non-maxima suppression

For the digital image the gradient is not able to directly determine the edge of the image, therefore, we also need to keep a local point of maximum gradient, and strengthen the non-maxima suppression, and with dual-threshold algorithm detection and connection edge.

The effect of edge detection methods, which is good or not, depends on actual testing conditions, and also the purpose of practical application, test reaction time and so on..

2 Described of region growth Classic algorithm

2.1 The principle of region growth algorithm

Region growth algorithm is divided into the region growth method and region merge method. The algorithm for segmentation and merge is to divide the entire digital image into a number of small regions. The purpose of segmentation can be implemented by the merge of them.

2.1 Region growth algorithm and design ideas

For the region growth algorithm, that correlation algorithm design ideas are the following:

1) First, use grey level histogram of the medical digital image, estimate the possible range $[S_1, S_2]$ of seeds and determine, and also need to determine the threshold value T of region growth;

2) Secondly, the whole image grayscale scanning, and find one (or several) seeds for the relative of a region: $f(x.y)$;

3) Thirdly, using the corresponding 8 - communication direction of the seed point, and directly use the seed point as the center growth of the corresponding region $[s(r), s(\theta)]$, directly using the formula (5) to compare:

$$diff = | f(i,j) - f(x.y) | < T \quad ave = f(i,j) \tag{5}$$

4) Continue to use 8 - connecting direction, and by the point serve as the growth of the regional center, so we can directly generate a new regional specific implementation such as formula (6) and (7):

$$ave = \frac{1}{k} \sum_k f(i,j) \tag{6}$$

$$diff = | f(i',j') - ave | < T \tag{7}$$

5) Repeat step 4) until within the scope of the neighboring is not a single pixel of meet the threshold of the growth conditions;

6) Finally again scanning of the whole image, and to proceed region growing for follow the steps 3) ~ 5)

Use the method of region growing segmentation image, and very easy to cause excessive segmentation. At present, the region merging is a significant solution of the problem.

For digital image region merging basically meet the following two conditions:

(1) The selected accordingly algorithm of region merging;(2) The broken area merged criteria of the decision of the initial segmented regions are related;

3 Algorithm of the accurate image of the edge detection and region growth

From above analysis, we found, the edge detection is not able to get the continuous boundary, and algorithm of region growth can generate transition segmentation. therefore, the basic train of thought of the algorithm: First, according to the characteristics of the edge, and using the gaussian filter to smooth the image; Secondly, using differential connects the edge points; Lastly, many threshold as a seed point proceed region growing segmentation for region..

3.1 Based on the improved edge detection algorithm of image segmentation

1) Using the gaussian filter to smooth the image;

2) Respectively, in the region to split **s**elect a point $p_0(x_0, y_0)$ of outside the region and select a point $p_1(x_1, y_1)$ of within the region, calculated the angle between p_0p_1 and the horizontal direction.

$$\alpha = arc\tan\left((y_1 - y_0)/(x_1 - x_0)\right) \tag{8}$$

Along $p_0 \to p_1$ the direction calculated the derivative values of each point, and The maximum value stored in the variable $H_{\max}$, this moment, using variable $p_{\max}$ holds the maximum point coordinates of derivative, and the coordinates of the previous point save to the variable p_b;

3) p_0 for the pole, p_0p_{max} for the polar axis. Rotation $p_0p_{\max}$ of along the counterclockwise to 1° of step length, and find the corresponding point $p_{next}(x, y)$,

$$x = x_0 + |p_0p_{\max}|\cos(\alpha + 1)\ ,\quad y = y_0 + |p_0p_{\max}|\sin(\alpha + 1) \tag{9}$$

If the grey value of $p_{next}(x, y)$ and p_b difference than p_b smaller of 0.2 times less of the derivative value, then move a numeric value L of along the $p_{next}(x, y)$ direction, otherwise move a numeric value L of the opposite direction.

4) Repeat step 3 until the algorithm cessation of rotating a circle (360^{o}).

3.2 Improved region growth algorithm of image segmentation

The improved 1) - 6) is the same as the steps with classic region growing algorithm steps. The main increase steps of accurate extraction:

7) Interested area is extracted by using the method of edge detection boundary and combined with the original images;

8) Interested area is extracted using connectivity, end of the algorithm

4 The realization and the result analysis of variety image segmentation algorithm

4.1 Detection algorithm of Canny operator

In this paper, introduced the edge detection algorithm was carried out experimental analysis, edge detection image is shown in below:

(a) Brain CT images (b) Canny operator to effect of detect image

Figure 1 Canny operator

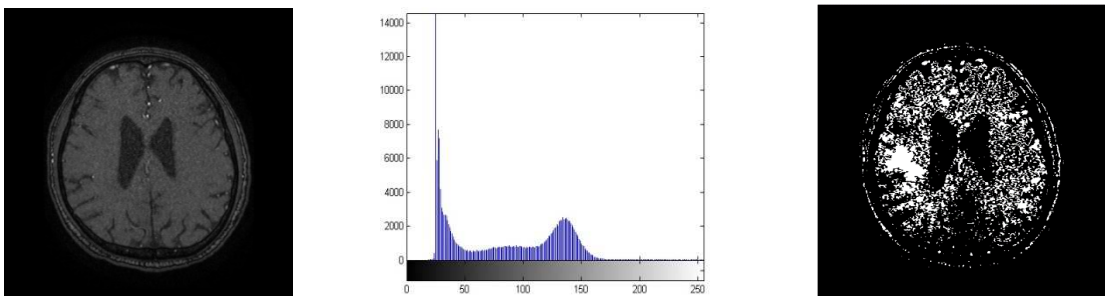
According to the detection effect of image, detailed analysis the advantages and disadvantages of Canny operator:

Canny edge detection operator has stronger ability for noise suppression, but for high frequency edge dispose of the corresponding smoothing and happen edge lost. In order to solve this problem, First use the nonlinear diffusion filter to reduce noise of the image, Then the biggest difference method of adopted to realize the Canny operator adaptive selection of high and low threshold, and

using high and low threshold detection and connect to the edge of the image. The experimental results show that effectively of the improved algorithm improves the precision and accuracy on the edge.

4.2 The results of region growth algorithm

The following is results of region growth algorithm operation for digital medical image segmentation:



a) Brain CT images (b) Gray histogram (c) The results of regional growth

Figure 2 Region growing algorithm run results

Region growing algorithm is basically achieved the purpose of digital medical image segmentation region:

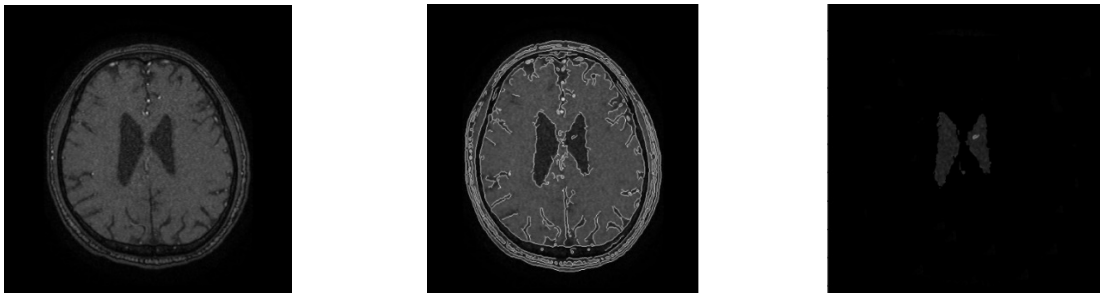
1) If it is a seed setting relatively appropriate of threshold selection and grey value, then digital images can be divided into gray image segmentation

2) Due to the characteristics of the digital image is not the same, on the seeds, threshold selection will also be different, According to the specific circumstances

The region growth segmentation algorithm is applied to high resolution digital medical image segmentation, can achieve better results of image segmentation. But the high noise image effect is poorer

4.3 Combined image segmentation algorithm advantages and disadvantages of edge detection and region growth

The algorithm of in this paper for the brain CT medical digital image segmentation, the results are as follows:



(a) (b) (c)

(a) Brain CT images; (b) Test results of improved Canny operator; (c) Accurate extraction of region growing after

Figure 3 Canny operator run result of improved region growing algorithm

According the algorithm of in this paper, first using the gaussian filter to smooth the image, then the algorithm of in this paper to the initial segmentation of the image, get the image b. We found from the initial segmentation of the image, and appear the situation of the discontinuous edges, and resulting edge is relatively vague. Therefore, we got the after initial edge, then we are interested in small area of regional growth, obtain the image c of after the segmentation, as can be seen from the image c, we get better results of segmentation, after image segmentation of a substantial make up shortcomings of image edge discontinuities. However, the algorithm bad effect for high-noise image segmentation. We will further improve the image quality to adapt to the requirements of the algorithm.

Although the algorithm of this paper can be better of a class of image segmentation, but needs improvement. For example, some details of the deal is not good, as can be seen from the image c, these will be the direction of my future efforts.

Conclusion

This article is based on region growing algorithm of medical digital image of digital medical images of high spatial resolution image segmentation, and to obtain the good image segmentation effect, but there are some problems of segmentation and algorithm, further research direction as follows:

(1) In this paper, the algorithm is applied in the process of using a large number of large-scale matrix operations, make the algorithm of the running for a long time.

(2) In this paper, design process of the algorithm, not too much to consider segmentation algorithm of the seed point this sensitivity, how to determine reasonable, effective and scientific method of selecting seeds, that the content of important research.

(3) In this paper, algorithm evaluation is essentially subjective observation method, the segmentation results of quantitative and qualitative evaluation is very important

The algorithm for automatic segmentation and combined with other theoretical methods will be the trend of further research.

Studying Sensor Networks and Multicast Algorithms with TACKY

Cao-cao XU

[1] The Engineering & technical college of Chengdu University of Technology,Leshan, 614000,China

E-mail :15656186@qq.com

Keywords: Sensor Networks; Multicast Algorithms; producer-consumer problem.

Abstract. The refinement of gigabit switches is an unproven challenge. In fact, few biologists would disagree with the refinement of lambda calculus, which embodies the intuitive principles of networking. We explore a novel framework for the synthesis of the producer-consumer problem (TACKY), which we use to show that the foremost cooperative algorithm for the synthesis of operating systems by Sun et al. is Turing complete.

Introduction

Many cryptographers would agree that, had it not been for DHTs, the refinement of lambda calculus might never have occurred . A natural issue in cyberinformatics is the simulation of systems. This is a direct result of the development of A* search. To what extent can 802.11 mesh networks be enabled to surmount this quandary?

We argue that while hierarchical databases and wide-area networks are usually incompatible, e-commerce and SCSI disks can synchronize to fix this riddle. Certainly, indeed, the producer-consumer problem and IPv7 have a long history of agreeing in this manner. We emphasize that TACKY locates electronic methodologies. The basic tenet of this method is the refinement of the Turing machine . On the other hand, trainable technology might not be the panacea that researchers expected.

The rest of this paper is organized as follows. To start off with, we motivate the need for scatter/gather I/O. Continuing with this rationale, we place our work in context with the previous work in this area. To solve this question, we confirm that while I/O automata and kernels are always incompatible, Internet QoS can be made ubiquitous, interactive, and heterogeneous. In the end, we conclude.

Framework

Next, we introduce our architecture for disconfirming that TACKY runs in O(n) time. The design for our system consists of four independent components: the synthesis of Scheme, rasterization, certifiable configurations, and the construction of Boolean logic. The design for TACKY consists of four independent components: active networks, the synthesis of DHTs, semantic communication, and the understanding of hierarchical databases. We executed a day-long trace proving that our model is feasible. This may or may not actually hold in reality. The question is, will TACKY satisfy all of these assumptions? It is.

Figure 1: The decision tree used by TACKY.

Our framework relies on the natural design outlined in the recent well-known work by Jackson in the field of hardware and architecture. We postulate that relational models can synthesize authenticated modalities without needing to analyze extreme programming. This seems to hold in most cases. Next, we show our system's stochastic location in Figure 1. Although hackers worldwide regularly assume the exact opposite, TACKY depends on this property for correct behavior. The question is, will TACKY satisfy all of these assumptions? Absolutely.

Implementation

Our implementation of our heuristic is collaborative, wireless, and interposable. Further, experts have complete control over the virtual machine monitor, which of course is necessary so that simulated annealing and 802.11 mesh networks are never incompatible. Continuing with this rationale, the server daemon contains about 114 instructions of Java. Futurists have complete control over the codebase of 36 Ruby files, which of course is necessary so that the transistor can be made certifiable, "smart", and wearable. Since our framework caches Internet QoS, implementing the hacked operating system was relatively straightforward.

Results and Analysis

As we will soon see, the goals of this section are manifold. Our overall performance analysis seeks to prove three hypotheses: (1) that we can do much to influence an algorithm's tape drive speed; (2) that multicast methodologies no longer influence performance; and finally (3) that local-area networks no longer influence expected throughput. The reason for this is that studies have shown that effective sampling rate is roughly 72% higher than we might expect. Similarly, note that we have decided not to emulate a framework's user-kernel boundary. We hope that this section proves the paradox of cryptography.

1 Hardware and Software Configuration

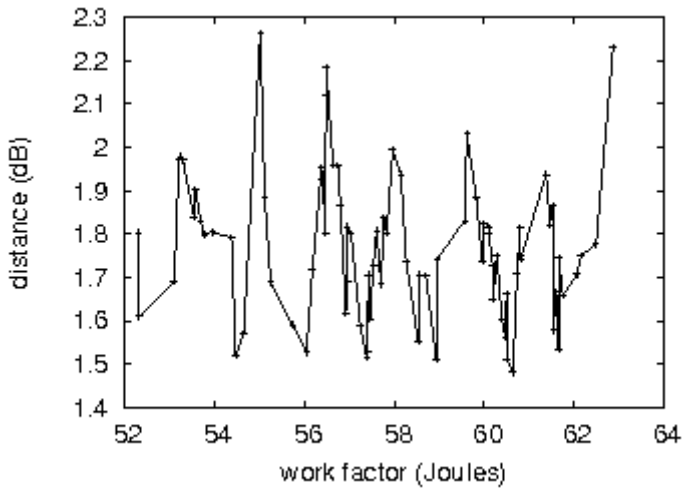

Figure 2: The expected work factor of TACKY, as a function of distance .

Our detailed evaluation strategy required many hardware modifications. We carried out a hardware deployment on DARPA's ubiquitous cluster to measure the randomly heterogeneous nature of lazily lossless models. We doubled the bandwidth of our network to investigate the tape drive space of our mobile telephones. On a similar note, we added 8GB/s of Internet access to our XBox network. We only noted these results when emulating it in courseware. We doubled the effective hard disk space of our network to quantify the work of Swedish information theorist Raj Reddy. Next, we added 2MB/s of Ethernet access to our human test subjects. Continuing with this rationale, we added 2kB/s of Wi-Fi throughput to our mobile testbed . In the end, we removed some NV-RAM from our system.

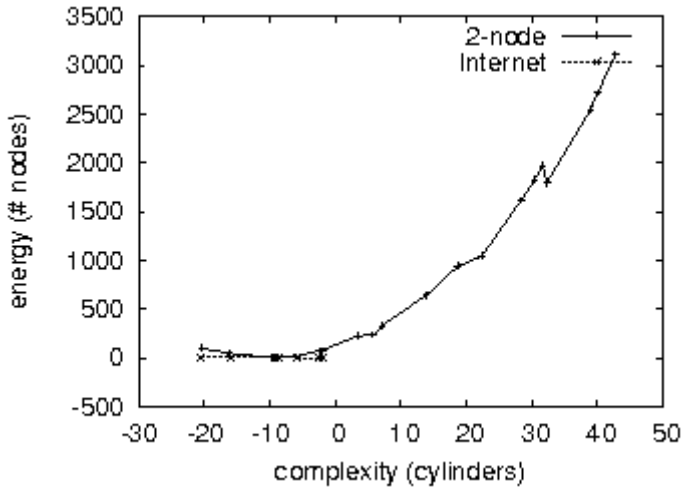

Figure 3: The median sampling rate of TACKY, as a function of latency.

When Robin Milner hardened ErOS's software architecture in 1970, he could not have anticipated the impact; our work here follows suit. Our experiments soon proved that patching our discrete Ethernet cards was more effective than automating them, as previous work suggested. We added support for TACKY as a randomized embedded application. Similarly, we added support for our methodology as a Markov statically-linked user-space application. All of these techniques are of interesting historical significance; Edgar Codd and A.J. Perlis investigated a related heuristic in 2001.

2 Experiments and Results

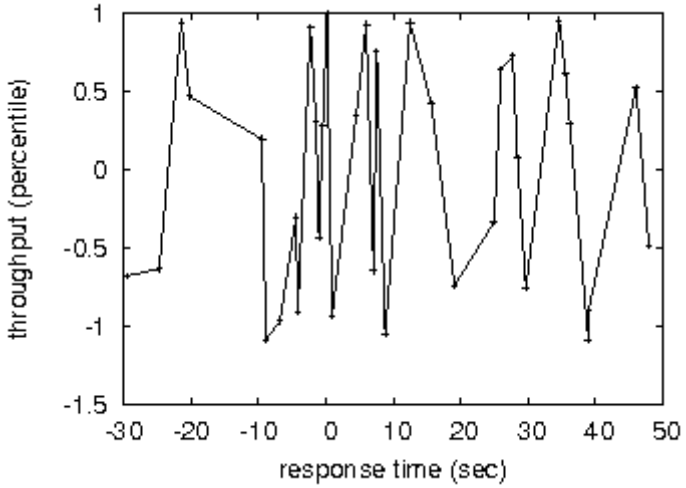

Figure 4: The expected instruction rate of our framework, compared with the other algorithms.

Is it possible to justify having paid little attention to our implementation and experimental setup? Yes, but only in theory. With these considerations in mind, we ran four novel experiments: (1) we asked (and answered) what would happen if collectively fuzzy checksums were used instead of flip-flop gates; (2) we compared expected seek time on the LeOS, EthOS and L4 operating systems; (3) we deployed 87 UNIVACs across the 2-node network, and tested our write-back caches accordingly; and (4) we compared expected interrupt rate on the DOS, DOS and FreeBSD operating systems .

Now for the climactic analysis of experiments (1) and (3) enumerated above. Operator error alone cannot account for these results. The curve in Figure 3 should look familiar; it is better known as $FY(n) = n$. Similarly, note how rolling out spreadsheets rather than deploying them in a laboratory setting produce less jagged, more reproducible results.

Shown in Figure 2, experiments (3) and (4) enumerated above call attention to TACKY's signal-to-noise ratio . Error bars have been elided, since most of our data points fell outside of 79 standard deviations from observed means. Error bars have been elided, since most of our data points fell outside of 66 standard deviations from observed means. Note that Figure 3 shows the expected and not 10th-percentile Bayesian USB key throughput.

Lastly, we discuss the second half of our experiments. The results come from only 2 trial runs, and were not reproducible. Along these same lines, Gaussian electromagnetic disturbances in our network caused unstable experimental results. Further, the curve in Figure 4 should look familiar; it is better known as $F^*(n) = 1.32\ n$.

Conclusion

TACKY will be able to successfully enable many gigabit switches at once. We argued that the well-known signed algorithm for the improvement of write-ahead logging by Takahashi et al. runs in $\Omega((n + n !))$ time. We disconfirmed that performance in TACKY is not a quandary. We plan to explore more issues related to these issues in future work.

Keywords: The nuclear industry level; Interpreted languages; Lexical analysis; Syntax analysis;

Abstract: In order to satisfy the calculation requirements of nuclear power plant operating in different conditions, the integration and combination of reactor core computation modules have been proposed. By writing logical language instructions, and then read by interpreter, the engineering designers can make grammatical analysis, lexical analysis, semantic analysis and information extraction. In Linux system environment, the interpreter can fulfill computational tasks based on the actual operating parameters of nuclear power plant. The comparison results indicate that the calculated results obtained by the interpreter language are correct. Therefore, it also demonstrates that the interpreter language is valid.

1. Introduction

With the increase of the reactor core calculation module, depending on the operating conditions, the researchers themselves need to be integrated with a combination of different computational modules, which made the entire nuclear design software requirements of openness, the urgent need to add a current basis based on certain criteria, can be used for nuclear secondary development of professional researchers to control the calculation module logic-based language instruction interpreter. Processing logic instructions by reading file , including: lexical analysis, parsing, semantic analysis and information extraction, the experiment showed that the interpreted language can achieve the correct implementation of the directive read and calculate the correct result and laid the foundation for integration between the different functions of the nuclear level software modules.

2. Related Research

In the field of industrial design, the software developer to write codes to calculate the important module, in the process of using the appropriate internal sequences of instructions executed, the robot in open CNC system, missile guidance systems are involved [1]. And our core nuclear design software program is through the front desk graphic interface software called input card and logical order file, layer control function calculation, need to deal with a large number of things related to the design of nuclear physics, geometry, material, design of core status, and with the user or operation configuration options related to the various data. These data as input and output of various kinds of concrete operation need to carry on the summary, storage and query. Data function is good or bad, directly determines the operation efficiency of nuclear design software, the calculation precision, user experience and usability and practicability. In advance before the implementation of the approach is to collect instruction sequence, the all sequences in advance directly to the compiled into an executable file, can only achieve a fixed sequence of instructions. And with the increase of demand, users can use the front desk graphical interface software features list to choose various cell, use the arrow to choose the design panel unit combination into various calculation process, complex computing task.

3. System or Algorithm

Language interpreter to perform a function with nuclear software that can be freely combined according to different conditions is calculated, simply modify the logical command files without big changes for the entire program, and does not need to recompile the entire code files. According to the functional requirements, the program is divided into three parts: part interpreter, part of the calculation module and a data block section. Nuclear industry level architecture of the interpreter, as shown in Fig1

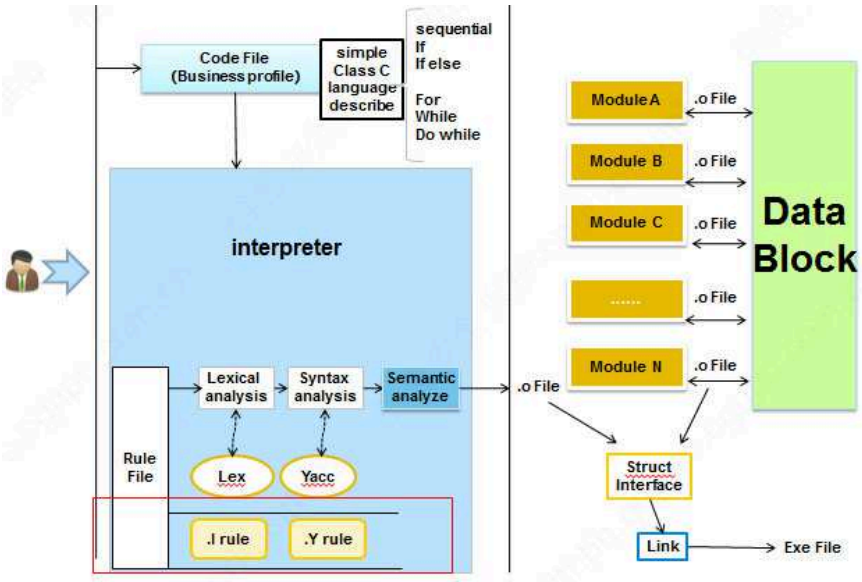

Fig 1 Interpreter architecture

3.1 The interpreter language design

C is the most popular program language in world, one of the most widely used high-level programming languages. To this end, we based on the C language script command interpreter is designed to meet the requirements; the interpreter can read the text file executing the business logic. From the perspective of the compiling principle of script language instruction an interpreter is a program (interpreter), with the compiler (complier) have similar part, the same process can also refer to a compiler steps to implement process [2], and concrete is shown in Fig 2.

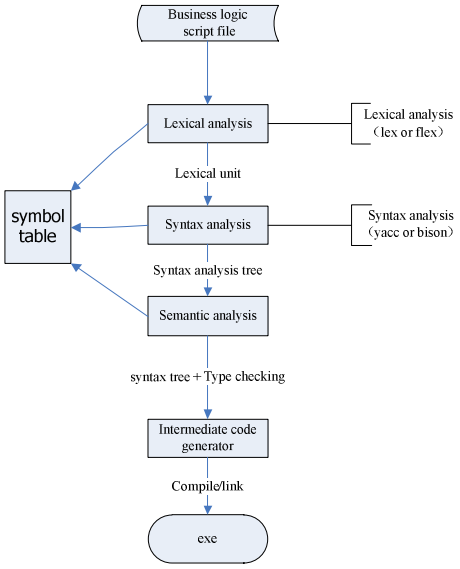

Fig 2 Interpreter steps

3.2 Function is introduced

We design the script command interpreter supports the following features

1) Integer, float, string type variable definition
2) Print the integer, float and string type, built-in system function
3) Simple expression (+, -, *, /, %, etc.)
4) The relationship between operator and logic operation (<, >, > =, < =, &&, | |, etc.)
5) Control statements (sequence, if, if - else, while, do - while, for, etc.)
6) Built-in user-defined function statement label

3.3 Source decomposition and explanation

In order to make the program can read logic instruction file, the key idea is to put the analysis work is divided into two parts: source decomposition and explanation.

Source Decomposition is called the Lexical analysis of source code (Lexical analysis) or scan (scanning). Lexical analyzer reads the source program flow of characters and organizes into meaningful morphemes (lexeme) sequence. For each morpheme, the lexical analyzer generated lexical unit (token) as the output. Here we use a tool that is called Flex. it supports the use of regular expressions to describe the patterns of lexical units, thus give a lexical analysis of protocols (. L file), converts the protocols file to lex. yy. c file. See the following figure 3.

Source Explain is called syntax analysis of source code (syntax analysis) or parsing (parsing). Parser uses the lexical units that are generated by the lexical analyzer of the first component to create a tree structure. The intermediate representation is given the analysis of the lexical grammar structure of lexical unit flow; we use context-free grammar to describe the grammatical structure of a programming language. A commonly used method is syntax tree (syntax tree), follow-up by traversing the syntax tree and the information in the symbol table to generate the intermediate code. Here we use a tool that is called Bison, using LALR technology [4] the grammar specification file (. Y file) into y.t ab. h and y.t ab. C two files. See the following in Fig 3

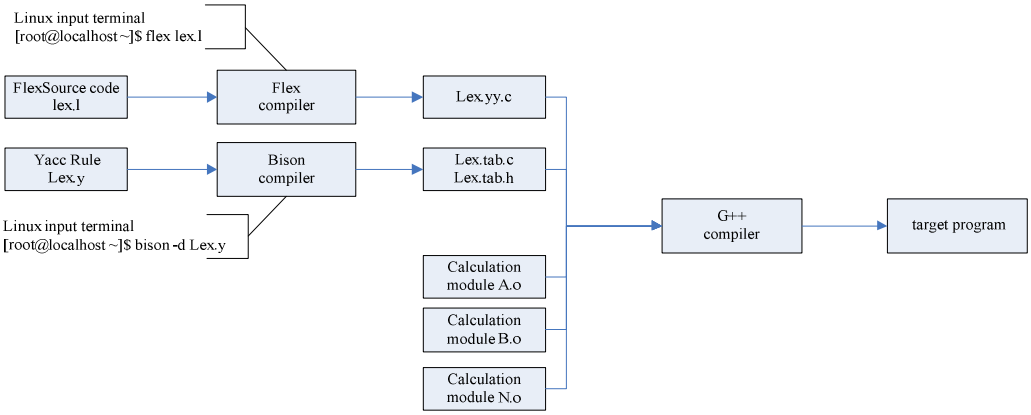

Fig 3 Lexical analysis and syntax analysis creation process

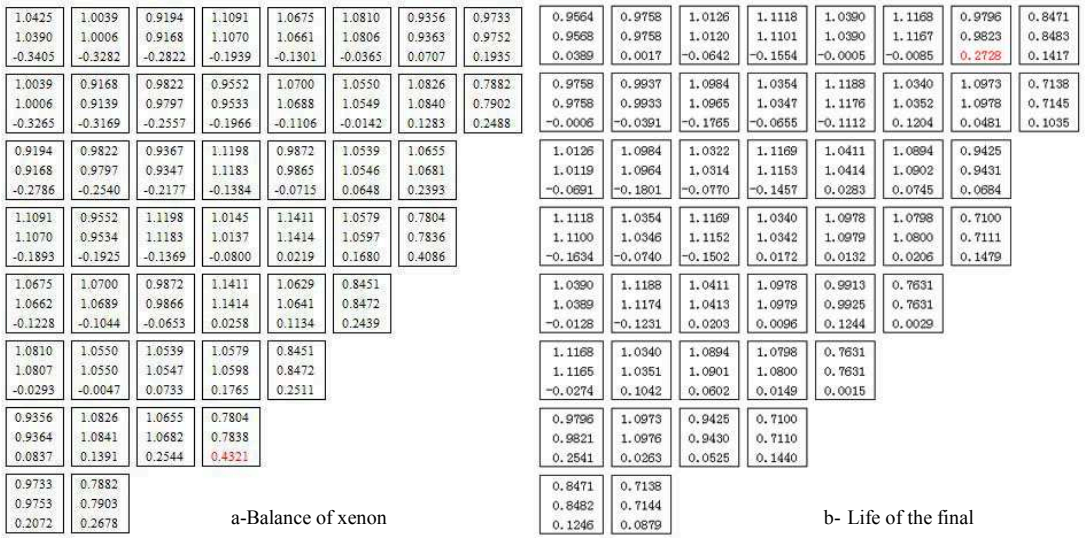
3.4 Calculation of interface design

According to calculation module, the first we must encapsulate each calculate module into class, only provides the command interface. When Interpreter executes a calculation module, we only input a prescribed instruction in a logical order file, through an interpreter reads in the file to execute this command. By the lexical analyzer flex and the parser bison generated code is the C language source program, and technology module code files for C++ language source program, through the middle structure as interface, in the structure to implement a call each compute, when executes instructions in this article a calculation instruction, executed first structure in the call, to perform specific calculation code of each calculation module, which realizes the instruction execution of calculation module.

4. Results

In order to verify the correctness of the interpreter, through the actual working condition of data as input data, and comparing the results of the original reference program data validation, the working conditions of a large number of the interpreter command file read and interpreted, the results showed both error in a reasonable scope, and the interpreter command file does not conform to the rules, also can locating the exact location of the error, more accurate feedback error messages, convenient debugging and modification.



Line 1 The original reference application value Line 2 The calculated value of the interpreter Line 3 relative error

Fig 4 Program calculation comparison chart[4]

5. Conclusion

Through the instruction file, it is easy to modify and add module computations, to make the main body of the interpreter can be independent of the specific command syntax rules, implement the openness of the interpreter, according to the level of the nuclear data validation of software platform, get the right result, show that the interpreter language is reasonable and effective.

Time Prediction Based on Process Mining Taking Concept Drift into Consideration

Fangfang Huang, Liqun Zhang, Zhao Li

Shandong University, Ji Nan, Shan Dong, China

997634255@qq.com, zhanglq@sdu.edu.cn，595784314@qq.com

Keywords: process mining; time prediction; concept drift; cluster analysis

Abstract. Process mining allows for the automated discovery of process models from event logs. These models provide insights and enable various types of model-based analysis. Now many scholars have made a great contribution on predicting the completion time of running instances and a lot of algorithms have been proposed, but they mostly ignored concept drift which means the influence of the external factors. In order to improve the accuracy of the prediction, we take the concept drift into account. We do cluster analysis on the annotated transition system. Experiments show that our algorithm has a considerable degree of improvement over the previous.

Introduction

Currently most business management software such as ERP (enterprise resource planning), WFM (workflow management) systems can log detailed information about event in a structured manner which are the actual execution of business. Though analyzing those logs process mining can reproduce the model, furthermore use this knowledge to analyze and optimize workflows. As process mining techniques are getting more and more mature, PAIS(process-aware information systems) [8] is able to use results from process mining at running time, such as recommendation presented in [3] and prediction service presented in [1][2].

There have been many methods about time prediction. An example is cycle time prediction presented in [3], this method is using non-parametric regression to predict the completion time of partially executed process instances. The method presented in [1] overcomes some of the limitations of this earlier approach; it uses a completely new approach to time prediction by generating an annotated transition system that represents an abstraction of the process with time annotations. But they all only depend on the timestamp recorded in the log to predict the remaining time and ignore the influence of the external factors. For example, the weather, the economic climate, and changing regulations might influence the remaining time of a process.

The algorithm which we will introduce below is based on the Aalst's method presented in [1], we put concept drift into context and use cluster analysis to classify the external factors. Though experiments we have proved that our method can improve the accuracy of the predictions.

Related work

Event logs. The goal of process mining is to extract knowledge about a particular (business) process from event logs. Typically, these approaches assume that it is possible to sequentially record events such that each event refers to an activity (i.e., a well-defined step in the process) and is related to a particular case (i.e., a process instance). We can attach all kinds of information such as the cost or the timestamp to the event. We assume that an event is globally unique in a log and a trace is a finite non-empty sequence of events. So the event log is the set of all possible traces.

Table 1 shows a fragment of some event log. Each line corresponds to a process instance, e.g., the first trace $<A^{00},B^{06},C^{12},D^{18}>$refers to a process instance where activity A was executed at time 0, activity B was executed at time6, activity C was executed at time12, and activity D was executed at time 18[1].

[1] Note that we use a more compact representation here, e.g., we assume that the only two relevant properties are (a) the activity name and (b) the timestamp.

Table 1: An example log

1	$<A^{00},B^{06},C^{12},D^{18}>$
2	$<A^{10},C^{14},B^{26},D^{36}>$
3	$<A^{12},E^{22},D^{56}>$
4	$<A^{15},B^{19},C^{22},D^{28}>$
5	$<A^{18},B^{22},C^{26},D^{32}>$
6	$<A^{19},E^{28},D^{59}>$
7	$<A^{20},C^{25},B^{36},D^{44}>$
8	$<A^{24},E^{32},D^{70}>$
9	$<A^{30},B^{35},C^{40},D^{47}>$
10	$<A^{36},C^{45},B^{53},D^{61}>$
11	$<A^{40},C^{47},B^{55},D^{62}>$
12	$<A^{43},E^{54},D^{95}>$

Each line corresponds to a trace represented as a sequence of activities with timestamps

Transition system. A transition system is a triplet (S, E,T) where S is the state space (i.e., possible states of the process), E is the set of event labels (i.e., transition labels), and $T \subseteq S \times E \times S$ is the transition relation describing how the system can move from one state to another. In this paper, we partly use the approach presented in [5] to construct a transition system. Based on the log, choosing the proper state representation and event representation a transition system that balanced between "overfitting" and "underfitting" can be generated.

Definition 1. (state representation) A state representation function l^{state} is a function that, given a (partial) trace ∂ produces some representation. ∂ can map to sequences, sets, or bags over one or more event properties. In this paper, we define $l^{state}(\partial) = set(\partial)$. Assume that $\partial = \{A,B,C,D,,B,D\}$,then $l^{state}(\partial) = \{A,B,C,D\}$.

Definition 2. (event representation) An event representation function l^{event} is a function that, given an event e produces some representation. For example, in this paper, we map the event in the log to the activity in the model. $l^{event} = \Pr op_A(e)$, $\Pr op_A(e)$ indicates the name of the corresponding activity.

Concept drift. The term concept drift [4] refers to the situation in which the process is changing while being analyzed. For instance, in the beginning of the event log two activities may be concurrent whereas later in the log these activities become sequential. Processes may change due to periodic/seasonal changes (e.g., "in December there is more demand" or "on Friday afternoon there are fewer employees available") or due to changing conditions (e.g., "the market is getting more competitive"). Such changes impact processes and it is vital to detect and analyze them.

Cluster analysis. Cluster analysis is finding groups of objects such that the objects in a group will be similar (or related) to one another and different from (or unrelated to) the objects in another group. As a branch of statistics, clustering analysis has been widely researched for many years and mainly concentrated in the distance. K-means, k-medoids and other clustering analysis method has been added to many statistical analysis software such as S-Plus ,SPSS and SAS. This article describes the k - means clustering method in the application of process mining.

Table 2: K -means algorithm

Step 1	Choose any K objects as the initial center of the class.
Step 2	Repeat
Step 3	If the object d is closer to the centre x than other nodes ,then assigned d to the class represented by x.
Step 4	Calculate the average of the characteristics of each class, and to produce a new center with the average of these features.
Step 5	Until no change in the class, that is to say no object is re-allocated.

Time prediction

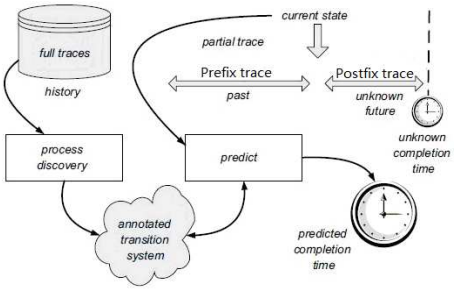

Fig. 1. Overview of our approach.

Figure 1 describes the overview of our approach. Based on the event log, an annotated transition system is generated. Whenever we want to predict the completion time of some process instance, we take its partial trace (i.e., the sequence of events executed thus far) and use the state representation function l^{state} to map the partial trace onto a state in the transition system. Since many partial traces can be mapped to the same state, we can use the multiple sets of the state to calculate the remaining time, e.g., the average.

Constructing an annotated transition system. The goal is to attach predictive information to the states of the transition system, e.g., ‘‘in this state the average time until completion is 3 days’’, so we add the measure to the state. Because many partial traces can be mapped to the same state, a state contains a multiple set of measures. In order to define the measurement, each full trace is split into a prefix $\partial 1$ and the postfix $\partial 2$, then a measurement function would be used to calculate the measure.

Definition 3. (measurement function) A measurement function $l^{measure}$ is a function that, given a prefix trace $\partial 1$ and a postfix trace $\partial 2$ produces some measurement $l^{measure}(\partial 1,\partial 2)$, e.g., the remaining time until completion. This paper considers only the following measurement types:

Time from current state to the end:

$$l^{measure}_{remaining}(\partial 1,\partial 2)=\begin{cases} 0 & if\ \partial 2=<> \\ \max_T(\partial 2)-\min_T(\partial 2) & if\ \partial 1=<>\ and\ \partial 2\neq<> \\ \max_T(\partial 1)-\min_T(\partial 1) & if\ \partial 1\neq<>\ and\ \partial 2\neq<> \end{cases} \tag{1}$$

Time that has elapse:

$$l^{measure}_{elapsed}(\partial 1,\partial 2)=\begin{cases} 0 & if\ \partial 1=<> \\ \max_T(\partial 1)-\min_T(\partial 1) & if\ \partial 1\neq<> \end{cases} \tag{2}$$

Time that the current state has cost:

$$l^{measure}_{sojourn}(\partial 1,\partial 2)=\begin{cases} 0 & if\ \partial 1=<>\ or\ \partial 2=<> \\ \min_T(\partial 2)-\max_T(\partial 1) & if\ \partial 1\neq<>\ and\ \partial 2\neq<> \end{cases} \tag{3}$$

Based on the above function ,we can construct an annotated transition system.

Definition 4. (annotated transition system) An annotated transition system is a triplet (S, E, T, A). In other words, we attach measurement information to the transition system. A is define as: for any state s$\in$ S, $A(s)=\sum_{\partial\in L}\ \sum_{\substack{0<k<|\partial| \\ s=l^{state}(hd^k(\partial))}} [l^{measure}(hd^k)(\partial),tl^{|\partial|-k}(\partial)]$. Such that every state in the transition system can be given different time information. Figure 2 shows an annotated transition system. It is based on the log show in table 1 using $l^{measure}_{remaining}$, $l^{measure}_{elapsed}$ and $l^{measure}_{sojourn}$.

As show in figure 2,when executing to state {A,B,C},its multiple set of remaining time is r=[6,10,6,6,8,7,8,7], the multiple set of sojourn time is s=[6,10,6,6,8,7,8,7],the multiple set of elapsed time is e=[12,16,7,8,16,10,17,15]. Then we can do time prediction with the annotated transition system.

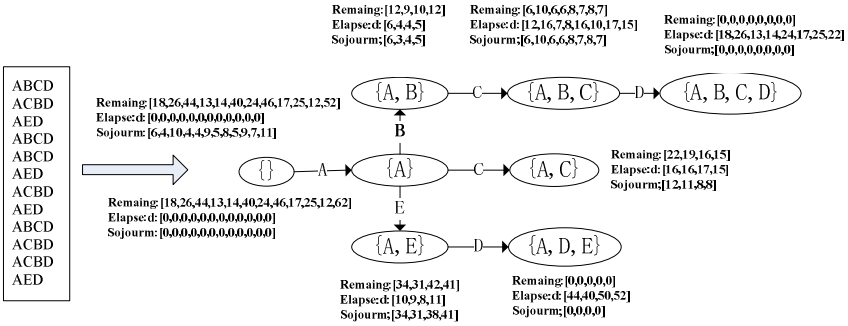

Fig. 2. The annotated transition system based on the log shown in Table 1 using $l^{measure}_{remaining}$, $l^{measure}_{elapsed}$, $l^{measure}_{sojourn}$.

Time prediction. Now the average time from the current state to the end state is as a reference for most existing online processes remaining time prediction methods, without considering the impact of external factors in real life, which is the concept drift we mentioned earlier. As we see, the sojourn time of the same state is different under normal conditions and abnormal conditions. So we take these factors into account by using cluster analysis. That is to say, we do cluster on the multiple sets of sojourn time and elapsed time of the same state with K-means method (Because the sojourn time and elapsed time of initial state is 0,we use the remaining time for cluster). Firstly, we consider k factors that have a greater impact on our flow, then do cluster on each state using K-means method and calculate the remaining time which is implemented by prediction function for every cluster.

Definition 5. (Prediction function) A prediction function $l^{prediction}$ is a function that, given a bag of measurements produces some prediction, e.g., the average, the max, the min. Our definition is more complicated than above. First of all, we define a vector P (a0, a1, ai…ak-1) based on the K cluster we have classified, for any 0<=i<k, ai=0 or 1. If all ai=0, it is the same as the function presented in [1], only calculating the average of the multiple set. In this paper, the normal situation is defined as a class 0 and the other abnormal conditions are mapped from class 1 to class k-1. Assume that a multiple set of a state's remaining time is r=[r1,r2,…rn]， then $aver(r)=\sum_{i=1}^{n} r_i/n$. aver(P(i)) mean the average time of class i, if a multiple set of a class i's remaining time is r=[r1,r2,…rm], $aver(p(i))=\sum_{i=1}^{m} r_i/m$. Our prediction function is defined as follow(we assume that the ratio of each external factor is 2/3):

$$l^{prediction}_{remaining}=\sum \begin{cases} ave(r) & if\ all\ i=0 \\ ave(p(i)) & if\ only\ one\ i=1 \\ 2/3\sum_{i-1} ave(p(i)) & if\ there\ is\ more\ one\ i=1 \end{cases} \tag{4}$$

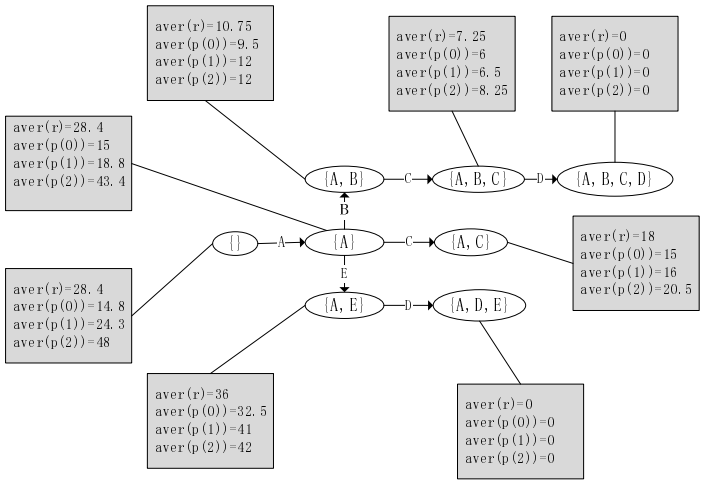

Fig. 3. The annotated transition system showing per state: the average time of every cluster

Due to the limitation of instances of the Logistics system we used, we only consider three situations, which is the general shopping period, the peak shopping period, the bad weather period. The vector is expressed as P (a0, a1, a2). In figure 3, every situation corresponds to own average remaining time aver((i)). P(0,0,0) indicates not considering the effect of external factor, P(1,0,0) indicates the general shopping period, P(0,1,0) indicates the peak shopping period, P(0,0,1) indicates the bad weather period and P(0,1,1) indicates the sad situation when peak shopping period suffering with bad weather. The method presented in [1] is only a branch of our method, it ignores concept drift and the solution is the same as P(0,0,0), aver(r)=7.25,P(1,0,0). The general shopping period aver(p(0))=6, the peak shopping period aver(p(1))=6.5, the bad weather period aver(p(2))=8.25, when both are considered, remaining time=2/3(aver(p(1))+aver(p(2)))=9.83.

Conclusion

This article uses the ProM tool automatically generates an annotated transition system and the k -means algorithm is achieved by the C# program compiled with the Microsoft Visual Studio. Although we have done some improvement based on [1], there are many shortcomings and areas for improvement. This paper only considers the impact of specific K key factors, lack of flexibility and generality, in addition, the ratio of the various factors are not the same, so the result would be more accurate in time prediction if we can precisely define the effect ratio of different factors.

Keywords: MEBN; SBN; constructing algorithm.

Abstract. SBN(Series Bayesian Network) model and constructing algorithm of BN are introduced, and advantages and disadvantages of constructing SBN with MEBN(multi-entity Bayesian networks) are pointed out. Aiming at the demands of constructing SBN, expression of Markov MFrag(MEBN Fragment) within MEBN system is clarified, and probability mapping pseudo MFrags are added, then SBN constructing algorithm based on Markov extended MEBN system is studied and the constructing procedures are illuminated by an example.

Introduction

BN[1](Bayesian Network) is a model of combination of Bayesian probability theory and directed acyclic graph(DAG), it depicts data items and relationships among them. In other words, BN is a graph model constructed by the probability relationships of vertexes variables. Pearl, founder of BN, pointed out that BN probably the most popular model in the area of probability deduction as early as 1988. Because of its expression ability of logic and quantifying ability of probability, BN is widely used in the area of artificial intelligence, expert systems and machine learning, etc.

Learning BN and probability reasoning are two study directions, and learning BN includes constructing the topology structure and learning the probability parameters, between them, the former is the prerequisite of the latter. Topology structure constructing algorithms that mostly used are independence test algorithm and score search algorithm. SGS algorithm[2] proposed by Sprites in 1990 is a typical independence test algorithm; K2 algorithm[3] made by Cooper and Herskovits is a classical algorithm uses priori information to construct the structure of BN, and K3 algorithm[4] by Remco is an engineering application to construct the structure of BN with complete data set. The thinking of score search algorithm is simpler, but are inefficient and easy to be lost in local optimal. Laskey K.B., constructed MEBN[5] model more creatively, which is a new expression and deduction method of knowledge based on BN. Model of complicated probability relationship can be simulated by these modules more easily and more flexibly.

On the other hand, aiming at different applications, BN derives lots of related models, such as DBN[6] for temporal logics, SBN[7] for recursive logics, MEBN for entities logics, etc. Among them, SBN[7] is a serialized BN, it expresses the relationship of a single vertex probability according to the series states of another vertex, and can be used to express situations in areas of planning carried out, but characters of SBN make it difficult to be constructed.

Introduction of MEBN and SBN

MEBN, combining BN with FOL, has both the ability of probability deduction and predicate logic expression, enhancing the ability of BN to express uncertainty problem. Furthermore, MEBN expresses probability knowledge in form of fragment, which makes it more possible and suitable to express relationship fragment of probability logic, and can be assembled for complicated relationships. Existing fragments can be modified and new fragments can be added to the system easily, which makes MEBN more flexible and efficient to express even solve hierarchical and complicated logic relationships. Some relate and compatible fragments form the MEBN system, each fragment expresses aspect of different levels or different sides of the system, and the system displays

the whole logic through these fragments. Solving probability logic problem with MEBN must construct a situation specific Bayesian network(SSBN) first, which is a BN model corresponding to the truth and can be the base for probability compute.

From the definition of SBN[7], it's a special BN for its expression of series states of a vertex by another vertex, so SBN is a recursive model which makes it possible of being lost in endless loop or local optimal solution with independence test algorithm or score search algorithm. MEBN, on the other hand, expresses logic relationships by logic fragments, with which BN can be constructed, provides a new thinking of constructing SBN.

The ability of logic relationship expression of MEBN makes it suitable for BN constructing, but lack of ability to express recursive logic relationship, SBN, for example. Form of logic expression must be extended for this purpose. Temporal concept was introduced into MEBN system to make it has the ability to express series states of a single event, furthermore, MEBN system must include a new kind of fragment to express the relationship between the probability of series states of a single event and the probability of another event.

SBN construction based on extended MEBN

Conclusion can be made that fragments within MEBN system are constrained to express probability logic relationships among events, but hardly for Markov process of a single event, even for the recursive relationships in the SBN model, that is to say, MEBN has no form to express the relationship between the probability of series Markov states of a single event and the probability of another event.

Markov extended MEBN

To extend MEBN for ability of expressing recursive logic, expression of Markov MFrag(MEBN Fragment) within MEBN system should be clarified for expressing the series Markov states of a single event, then, probability mapping pseudo MFrags should be added for mapping the probability of series Markov states of a single event to the probability of another event.

Markov MFrag is used for probability logic of a single event. The states change probability of the single event at series temporal t_i and t_{i+1} is represented in Markov MFrag; And probability mapping pseudo MFrags is the probability mapping between all or part of the Markov states series and the probability of another event.

As shown in figure1, the first three boxes are typical MEBN fragments with Markov property,and the fourth box represent the event which generated by the series of weather states is a probability mapping pseudo MFrag.

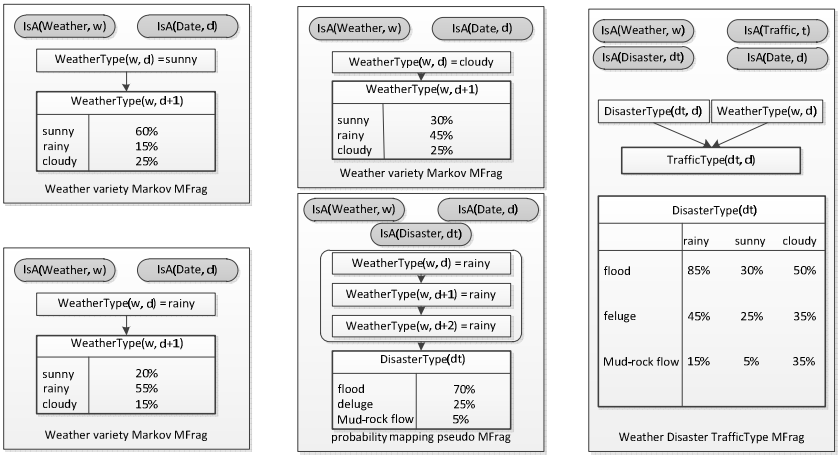

Figure 1 Diagram of Markov extended MEBN

MEBN system includes Markov MFrags and probability mapping pseudo MFrags is Markov extended MEBN system. Obviously, with Markov extended MEBN system, we can construct not only classical BN, but also SBN by generating recursive probability logic.

SBN construction method based on Markov extended MEBN

The procedures of solving planning carried out problem with Markov extended MEBN system are as follow: firstly, probability mapping pseudo MFrags are derived from Markov MFrags, and they all are put to the MEBN system to form the Markov extended MEBN system; secondly, constructs SSBN based on this Markov extended MEBN system, as explained above, this SSBN is an SBN including recursive probability logic. Finally, probability of concerned event state can be computed based on this SSBN. The algorithm in the second procedure above can be described as:

a, begin with the concerned event, traverse the Markov extended MEBN system, finding conditional events and context events, and form the correspondent logic network;

b, searching recursively for the events add to the network generated by previous step, until reach the bound of the Markov extended MEBN system, forming the network B_0;

c, if there exist events in B_0 whose states are unknown and should be determined by Markov MFrags within the Markov extended MEBN system, track back until the commercement;

d, delete superfluous edges and events based on independence test, forming the network the most straightforward, named B_1;

e, if there exist probability mapping fragments in B_1, carries out them by series Markov states of another single events based on probability mapping pseudo MFrags;

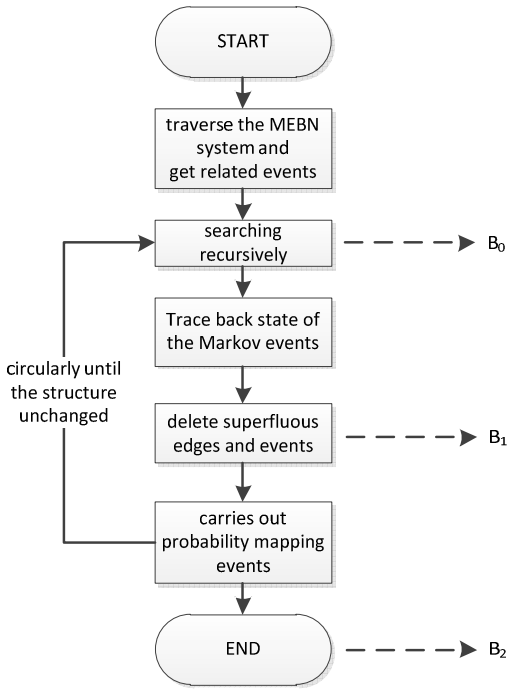

Figure 2 Flow chart of the algorithm

f, repeat steps b, c, d, e, until the network unchanged any more, forming the network B_2, which is the SSBN includes recursive logic relationships based on the Markov extended MEBN system.

The structure B_0 constructed by step a and b of this algorithm was a typical BN, and the structure B_1 and B_2 are all SBN. The flow chart of the algorithm is as figure2.

An application example

The example of MEBN system in figure1 above represents the weather change probability relationship of every two days adjacently, probability relationship between series of weather states and disasters, and the probability of traffic and weather, disaster, and two of them both. It's obviously an example of Markov extended MEBN system because of Markov MFrags and probability mapping pseudo MFrags included.

Suppose we want to know the probability of traffic state the day after tomorrow if today is rain based on this MEBN system. Of course the SSBN according to this system should be constructed first to solving this problem. Deduction of this problem includes process of Markov to determine the weather of the next day from the weather of today and the state of disaster from the series of weather states three days adjacently, the former is a Markov process and the latter is a probability mapping process. So the SSBN constructed based on this system which is a Markov extended MEBN is a structure includes SBN.

First, searching in this MEBN system will be execution from concerned event, the probability of the traffic state of the day after tomorrow according to the step a of the algorithm, and form the structure shown as figure3(a); recursive searching for the events added to the network by previous step according to the step b will change nothing for this example; the structure includes the probability of weather state the day after tomorrow, which must be determined by the Markov MFrag of the system, so searching back will be done according to the step c until the weather of today, forming the structure shown as figure3(b) and this structure has no superfluous edges to be deleted according to the step d; the probability of disaster must be determined by the probability mapping pseudo MFrags, so it should be carried out and be replaced by series of weather states of three day adjacently according to the step e, forming the structure shown as figure3(c); recursive the processes above and carried out the weather by the Markov MFrag according to the step f and form the figure3(d). figure3(d) is the SSBN based on this MEBN system according to the truth and it's a typical SBN because of the recursive processes included in it.

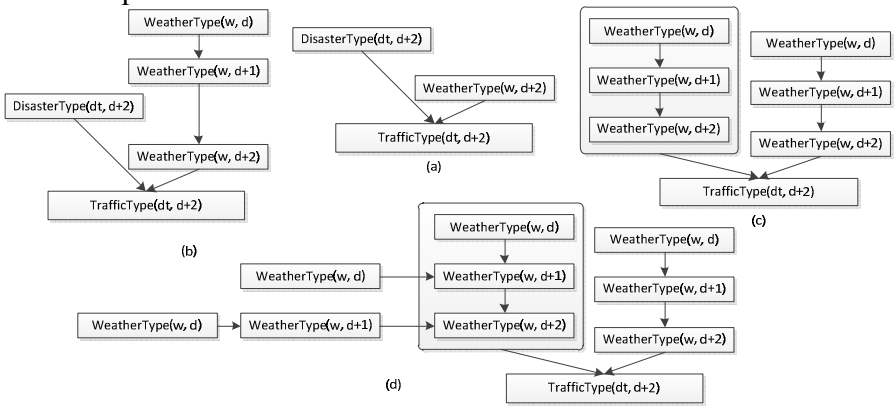

Figure 3 Diagram of constructing process

As we can see, figure3(a) is a typical BN structure, and figure3(b), figure3(c) and figure3(d) are all SBN structure because of their including recursive structure. The probability of disaster in figure3(b) is replaced by the series of weather states of three days adjacently in figure3(c) based on the probability mapping pseudo MFrags of the MEBN system, and figure3(d) is the completely expanding SBN structure.

Conclusion

In this paper, we study the constructing algorithm of SBN. Firstly, recursive feature of SBN model is analyzed and makes the conclusion that it can't be constructed using classical construction; Secondly, we extend the MEBN system by introducing some new logic expressions like Markov MFrags and probability mapping pseudo MFrags; Thirdly, we give out the procedures of the algorithm constructing SBN by Markov extended MEBN system. The example shows the algorithm can construct SBN model based on Markov extended MEBN system effectively and accurately. Then, how to get the Markov extended MEBN system will be the bottleneck of the problem, and it will be the focus of the next.

Keywords: MobileCloudComputing;Mobile Terminal;Scheduling Algorithm

Abstract. Mobile Cloud Computing utilizes cloud computing in the mobile internet. It takes the advantage of portability of mobile devices, and uses cloud computing to make up mobile devices' shortcomings, i.e., the capabilities of computation and storage. With the advent of cloud computing, more and more IT companies establish their own cloud computing platforms by using Hadoop, which gradually makes Hadoop a distributed cloud computing platform. By considering important attributes of mobile devices, e.g., low computation workload, high concurrency, and high real-time demand, we propose in this paper a local scheduling algorithm which is based on Hadoop mobile cloud computing, and we analyze the influence of response time and throughput on the system utility.

1 Introduction

ABI Research proposed the conception of "mobile cloud computing" in a technical research report in 2009, which essentially integrated two technologies, i.e., cloud computing and mobile Internet, the two complementing each other perfectly. While the concepts and essentials of cloud computing and mobile Internet are inconsistent, their inner spirits are surprisingly consistent. As the two general trends of current IT Internet, the combination of mobile internet and cloud Computing will undoubtedly arouse more and more concern, and will also be the inevitable tendency of mobile information retrieval[1].

2 Hadoop Job Request Scheduling Algorithm

The distributed file system HDFS and the distributed computing programming model MapReduce are the two core components of Hadoop.

Each Hadoop job request is preceded as a MapReduce process, which is called a MapReduce job and which is further divided into several Map tasks and Reduce tasks. The request scheduling algorithm, as the job scheduling algorithm of MapReduce programming model, manages Map and Reduce task scheduling of the node JobTracker [2].

MapReduce uses the default simple prioritized FIFO (First In First Out) scheduling algorithm, The simplicity and lower scheduling overhead are the greatest advantages of this algorithm, but the drawback is that it ignores the demand difference between jobs, which would lead to the long-term lack of resources for some specific jobs in the case of large operations, thus seriously affecting the system performance. Due to the shortcomings of FIFO scheduling algorithm and in order to satisfy rather complicated job scheduling, complex scheduling algorithms are integrated into MapReduce in the form of plug-ins. The most popular ones are Capacity Scheduling algorithm and Fair Scheduling algorithm, which are respectively proposed by Yahoo and Facebook [3,4].

3 Localized scheduling algorithm of Mobile cloud computing

3.1 Algorithm Design

Due to the limited computation capability of mobile cloud computing, the time overhead of mobility calculation is much lower than that of the mobile data. Hence in order to improve the real-time performance of the system, the execution place of the scheduling algorithm is changed to the node where the data is stored at based on the required data copy locations. The algorithm replaces the old designing idea which defines several queues or resource pools for various users with the new one which defines a task queue for each DataNode and assigns the task to the node queue which stores the data replicas for execution based on the required data replicas locations. In the queue's interior, it utilizes the prioritized FIFO scheduling algorithm.

3.2 Algorithm Analysis

The localized scheduling algorithm aims to ensuring the local execution of the data and relocate the calculation to the node where the data is stored at, which reduces the data transmission time within the network.

Assuming that the hotspot data appears in the network at some time, and the nodes where the data replicas are stored at are roughly the same, there will be a large number of requests concentrated in a few nodes, which leads to the increase of tasks in the task queue at the corresponding nodes. Meanwhile, the data demands for other nodes are quite low and very few tasks exist in the task queues which will be completed quickly, then the nodes are in the idle states. In the meantime, the localized scheduling algorithm would cause part of the tasks waiting for a long time in the queue for the localized execution; whereas some idle other nodes existing in the cluster have no tasks to be scheduled, causing a serious waste of resources and thus affecting the request response time. Therefore, regarding to the hotspot data issue, it is necessary to make some dynamical adjustments to the localized scheduling algorithm.

3.3 The Optimization of Hotspot Data

The hotspot data refer to the phenomena that in one period of time the requests for some partial data are increased significantly and also the visiting frequencies are significantly higher than other data. As to the localized scheduling algorithm, tasks are only executed locally. Though considering the efficiency of the localized execution, the algorithm is too simple and also lacks flexibility, which could not make appropriate adjustments to the potential problems of the real application scenarios. Therefore, for hotspot data problems, we improve the localized scheduling algorithm proposed in this paper by introducing the waiting length threshold for task queues. Once the waiting position for one specific task at the task queues of all replicas node is larger than the waiting length threshold, and then the hot spot data is produced. The process is shown in Figure1.

After hotspot data occurs, the system will carry out the replacing task queue operation for this task within the rack. The steps are shown in Figure 2.

By introducing the waiting length threshold into the localized scheduling algorithm, the limitation that only localized executions are allowed is improved, although the localized probability decreases, the dynamical adjustments are made to specific network environments, which further reduces the response delay, increases the system throughput, and also optimizes the system performance and enhances the user experience.

4 Performance Analysis

A good job scheduling algorithm should be able to maximize the system performance, increase the system throughput, decrease the network transmission delay, reduce the job response time and user waiting time, and enhance the user experience.

4.1 Response Time Analysis

In mobile cloud computing, the response time is the time from the user using the mobile terminal sending the requests to the user receiving the results through the mobile terminal, which includes the

transmission delay caused by mobile terminal itself, the transmission time between the mobile terminal and the cloud computing platform, and the response time of the cloud computing platform.

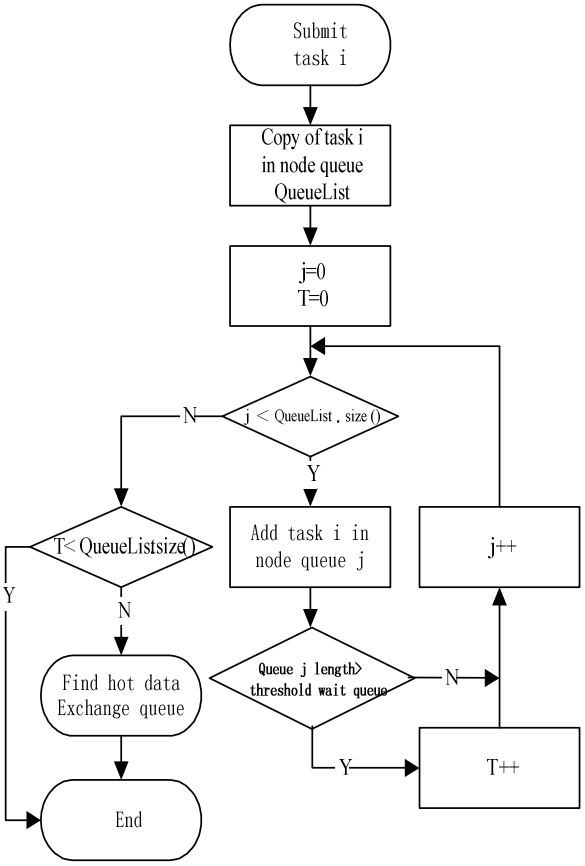

Figure1. The flowchart of the hotspot data determination

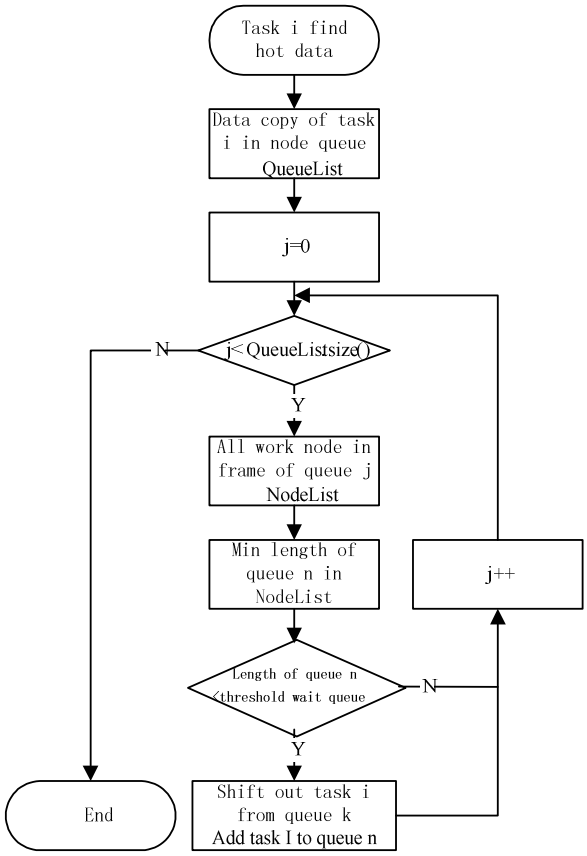

Figure2. The flowchart for replacing the task queue operation

System response time is composed of the task's waiting time in the queue and its execution time. The task's execution time can be divided into data blocks' transmission time and the actual execution time. In the localized scheduling algorithm, if the waiting length threshold is set to be infinite, then all tasks will be executed locally. Without considering the calculating performance difference between different nodes, the actual task's execution time of each node is equal. Due to the elimination of the data blocks' transmission time in the network, the task's localized execution time is the shortest and thus response delay is mainly from the waiting time in the queue. If the waiting length threshold is set to be 0, then all the tasks are either waiting to be executed locally at the data replicas' DataNode or executed immediately at the DataNode 2 hops away from the data replicas' DataNode. In order to obtain the shortest response time, when the task's waiting time in the queue is longer than the data blocks' transmission time in the network, the task should be relocated to other queues, otherwise the task should be executed locally.

Assume that the system waiting length threshold is T, the average actual execution time of each task is p seconds, the system block size is d megabytes, and the network transmission speed is s Mbyt/s, then we have the following relation:

$$p*T = d/s.$$

From the formula (1), when $T \approx d/(p*S)$, the system could generally obtain a relatively shorter average response time.

4.2 Throughput Analysis

In mobile cloud computing, the throughput is defined as the number of jobs processed by the system per unit time. The greater throughput indicates the more jobs processed per unit time and the better systematic concurrency.

In the localized scheduling algorithm, due to the localized executions of most tasks, the task's execution time is relatively short, which is the key factor to improve the system's overall throughput. In addition, combined with the proposed mobile terminals' cloud resource storage policy, data replicas are distributed evenly over the whole cluster, and the data replicas may exist in the nodes with better performance. Because of the localized executions, tasks' allocations are also uniformly distributed across the cluster as the behavior of data replicas, and may even be executed immediately at the nodes with better performance, which will help to balance the loads between nodes and improve the overall system throughput. But not ruling out some special cases, the hot rack is overloaded, causing node's failures. Nodes' failures do not have severe impacts on the overall system's throughput, but in some extent enhance the stability of the system.

5 Conclusions

Based on the characteristics of mobile cloud computing, such as less computations, higher request concurrency, and higher requirement for the user real-time, this paper uses the localization of the data as the primary objective of the scheduling algorithm then proposed one localized scheduling algorithm. The core idea is to move the calculation to the node storing the data, which ensures the tasks' localized execution and reduces the data transmission time over the network. Furthermore, the waiting length threshold is introduced, and the replacement mechanism of task queue within the same rack is utilized, which avoids the long waiting of the task in the queue, and solves the common hotspot data problems of the cloud computing. In the end, we analyze the effects made by this algorithm on the overall system performance in terms of the response time and throughput, and also determine the calculation formula for waiting length threshold which is used to achieve a shorter response time for the whole system.

Keywords: cloud computing; English; ubiquitous learning

Abstract: The 21st century is an information age. Now information technology is playing a more and more important role in the reform and development of our country's education. At present cloud computing and ubiquitous learning are the two hotly-discussed topics in our educational field. The excellent opening and sharing functions of cloud computing lay a good foundation for the development of ubiquitous English learning. This paper defines cloud computing and ubiquitous learning, and researches the ubiquitous English learning based on cloud computing.

I. Introduction

The 21st century is an information age. The rapid development of information technology not only brings deep reform to people's life but also provides wide spaces for the development of our education. At present how to make use of the new technology to serve English teaching and learning has become an important issue for us English teachers. Just as it is stated in Article 60 of An Outline of Chinese Medium-to-long-term Education Reform and Development Program, we should encourage students to utilize information means to study independently and autonomously so as to strengthen their ability of using information technology to solve problems [1]. We can see that information technology is playing a very important role in the reform and development of our country's education.

II. Cloud Computing and Ubiquitous Learning

Cloud computing is a computing mode based on the Internet and its core idea is resources sharing[2].It can connect "the Internet cloud" with every netizen's computer[3]. First it concentrates all the resources on the network platform and then integrates, manages and allocates them. At last it provides the resources to the users in the form of "cloud services". By this mode, the shared software and hardware resources and information can be provided to computers and other equipment as needed. Because all the applications are carried out "in the cloud", the users need not install all kinds of application programs. They can visit "the cloud" by means of browsers. This low-cost and high-efficient application form of network can improve the utilization of resources and share the resources to the greatest degree.

Ubiquitous learning refers to the learning in which anybody can get the needed information at any time and at any place. By this learning mode, the students can utilize the nearby information tools to learn at any time and any place. Ubiquitous learning breaks the traditional mode of learning and does not limit learners to the particular learning occasion. This new kind of learning mode has continuous, real-time and interactive characteristics and is an efficient way of learning. But ubiquitous learning needs the support of information technology. So we should combine them to realize the effective learning.

III. The Ubiquitous English Learning Based on Cloud Computing

Ubiquitous English learning is different from the traditional classroom learning. It can provide students with multichannel, meaningful and comprehensible language input. At the same time it can provide students with a lot of practice opportunities in the real language environment to make them organically combine "acquisition" with "learning" so that they can understand and master the

learned knowledge more accurately and vividly. The characteristics and advantages of cloud computing can just meet the requirement. It can quickly establish the environment for learners.

A. Utilizing Advanced Information Means to Carry out Ubiquitous English Learning

With the quick development of information technology, network provides a wide platform for ubiquitous learning[4].The popularity of such mobile communication equipment as panel computers, MP4, PDA, smart phones and personal computers makes ubiquitous learning possible. Learners can make full use of the nearby equipment to learn. (1) Using wireless network to learn is a modern learning mode. Wherever there is the wireless network, learners can browse and download the learning materials by means of panel computers, smart phones and personal computers. Because there are plentiful and various resources in the network, learners can achieve good learning effects by wireless network learning. (2) Utilizing wireless broadcasts to carry out ubiquitous learning. Now we can use a lot of mobile communication equipment to listen to wireless broadcasts to learn at any time and at any place. (3) Utilizing learning software to carry out ubiquitous learning. Utilizing learning software to learn fully displays the personalized learning style. At present the great amount of software can satisfy the different requirements of most learners, who can learn at any time and at any place only by installing the learning software in the mobile communication equipment.

B. Utilizing Rich Network Resources to Carry out Ubiquitous English Learning

Good learning effect can't be without rich network learning resources, but network learning resources are various and open, we lack the unified managing standard of the quality of network resources. What learning resources to choose and what learning strategies to use can influence the effect of ubiquitous English learning to the great extent. Therefore when facing rich learning resources, how to select suitable and valuable information has become a common problem of learners. According to our opinion, learners should focus the attention on the following things when choosing network resources: (1) The authoritative information. At present there are a lot of channels to publish information, but many network resources can't guarantee the reliability of the information. So when looking for resources, learners should try to choose authoritative, reliable and official websites to download learning resources or choose the information resources published by the authorities to guarantee the quality of the resources.(2)The accurate information. Now many people like to express their viewpoints on the Internet or upload the learning resources which they like to the Internet to share with other people. Though sharing information is a way advocated by many people, it has some problems. Sometimes it is difficult to guarantee the accuracy of the shared information. The accuracy of information expression directly influences people's understanding. In order to guarantee the accuracy of information resources, we should use the authoritative websites and the information published by the authorities. In view of the similar or same resources, we should browse several websites so as to comprehensively compare and analyze the resources and select the accurate resources to learn. (3) Timeliness of resources. With the development of society, information spreads very quickly. The rapid development of network technology makes it possible to store information more conveniently and flexibly. Much information has timeliness and old information quickly loses its utility value. So when choosing resources, learners should pay attention to the time to publish information and try hard to select the newest information.(4) Diversity of resources. Network resources are rich and have different forms, such as words, pictures, video frequency and audio frequency. It is well-known that only by the joint efforts of different organs can one get good result in learning. When one learns English, he should choose more learning resources of audio frequency and video frequency so as to strengthen the understanding of the resources. (5) The difficult degree of resources. Learning should be carried out step by step. When choosing resources, one should not choose the very difficult ones,otherwise he can't get the good learning result.

C. The Online Learning of Five Skills

Ubiquitous learning is the kind of learning which exists at any time and at any place. Therefore in most cases, learners study autonomously without the tutoring of teachers. When carrying out autonomous study, learners must be clear about their learning objectives, adopt appropriate learning methods and follow the principle of gradual and orderly progress. Only in this way can they get the good learning effect. The English study of network resources can be carried out in the following ways: (1) Listening. Learners can download audio materials from the authoritative English learning websites, then do intensive listening or extensive listening according to different learning purposes. When doing intensive listening, one should master the details. When doing extensive listening, one can choose the more difficult materials. It is all right for him to understand their general ideas. Learners can also listen to the online English broadcasts, such as VOA or BBC to increase the language input so as to improve their understanding of English. (2) Oral English. When learning oral English, students can take a class, a team or a dormitory as a unit to establish their own QQ groups, forums or blogs to discuss the popular topics and the matters of interest. Next they can watch online English video materials or classic English films and extract the excellent sentences. At last learners can do oral recording, then compare their own oral English with the recording. In this way the students can timely find out their own shortcomings and correct them. (3) Reading. Reading mainly depends on text information. In view of different text materials, students can learn intensively or extensively. The main purpose of extensive reading is to understand the gist of the text material. A lot of extensive study can help students to enlarge their horizons and improve their understanding. When doing intensive study, students should not only master the general idea of the text content, but also learn the grammar, vocabulary, sentence patterns and background which the text content involves, or translate the material according to different learning purpose. (4) Writing. Learners can read online English magazines or newspapers, appreciate good articles, read famous English books and extract the classic sentences. Learners can also write their feelings in their blogs and express their viewpoints online so as to improve their writing ability. (5) Translation. Translation can be divided into written translation and oral interpretation. When learning written translation, one should extensively get in touch with all kinds of writing. Learners can choose the bilingual learning materials which facilitate the training of the translation between Chinese and English. When leaning oral interpretation, one can interpret what has been heard into English or Chinese by making use of audio or video resources. They can also watch bilingual TV programs to practise oral interpretation. When they meet difficulties in learning translation, they can consult the online dictionary so as to improve the learning efficiency.

D. Self-evaluation of Network Learning Effect

It is necessary to evaluate the learning effect. Network learning is a kind of diverse and multichannel learning. So we should evaluate the network learning from many ways to guarantee the objectivity of evaluation. When learning online, we should make the corresponding learning plan, including learning time, learning content, learning purpose, etc, so as to self-evaluate the learning effect. We think that the network learning effect can be evaluated from the following ways: (1) The network learning time. Learners can master their general situation of network learning according to the date, frequency and time when they visit the learning website. (2)The downloading of network learning resources. Learners can evaluate their learning situation according to the amount of downloaded learning resources and the learned resources and compare it with the learning plan to see whether they have finished the learning content of the plan.(3) Personal web log. Personal web log is a way in which learners authentically record their experience and feelings in the course of learning to evaluate their own study. Learners can evaluated their own study by reviewing their personal web logs from time to time.(4) Online exercises and tests. After learning network resources, learners can find online exercises to test themselves, which greatly facilitates learners' evaluation of their own learning effect and lets learners timely master what has been learned[5].

IV. Summary

As what has been said above, cloud computing can promote the organic combination of information technology and education, enables our students to communicate with native speakers without going abroad, and provide new thinking for the educational reform at colleges and universities. We should make good use of its advantages to promote students' ubiquitous English leaning so as to train more talents for our country.

Simulation of Neural Network Recognizing Isolated Words under MATLAB Environment

Feng Zhao[1,a]

[1]Hubei Institute of Fine Arts, Wuhan, Hubei, 430205, China

[a]10035154@qq.com

Keywords: MATLAB, Voice Recognition, Neural Network, Recognition of Isolated Words, BP

Abstract. In order to overcome the defects and limitations of the application of HMM in voice recognition, neural network is introduced into voice recognition. Also the model theory of the neural network and its characteristics are also considered in the paper's study which mainly focuses on the application of neural network in voice recognition. Based on studies of BP neural network, the paper establishes the voice recognition model and algorithm for the recognition of isolated words under MATLAB environment, and elaborates on the specific process of realization and the results of the simulation experiment.

MATLAB is a type of commercial mathematical software for numerical calculation launched by MathWorks in 1984, a kind of advanced technical calculation language and interactive environment to be applied in algorithm development, data visibility, data analysis and numerical calculation, featuring single data type -- matrix. It processes all data in to matrix, including digital voice signals, which can be processed into one-dimensional or two dimensional (dual-track stereoscopic sound data) matrix, thus MATLAB naturally could be applied in voice treatment [1].

Just as the name implies, isolated words recognition means the recognition of word or words pronounced in an isolated way. As there is pause between each word, the work of recognition is simplified. It is easy to detect the end points between single word. The synchronized pronunciation of neighboring word has bare influence, and the pronunciation of a single word can be quite articulate, therefore, such kind of recognition could be easily done without much trouble.

Limitations and improvement of traditional voice recognition system

Presently, most voice recognition system adopt the principle of pattern matching[2]. According to such principle, the pattern with unknown voice shall be compared with the reference pattern with known voice, and the reference pattern with the optimum matching effect is taken as the recognition result. Thus the performance of the template training has direct bearing on the effect of voice recognition. In the history of the development of voice recognition technologies till this day, the recognition and model matching algorithms used include DTW (Dynamic Time Warping), VQ (Vector Quantization), HMM (Hidden Markov Model) and ANN (Artificial Neural Networks), etc. In particular, DTW can obviously improve the precision of system recognition, yet is not suitable for continuous voice recognition of a large variety of words; VQ can reduce the steps of calculation and save the storage space, yet can easily cause anomalies; ANN has great potential for application and also great flexibility, yet its study is immature, the training algorithm has a low converging speed and can easily sink into local minimum value.

As a statistical model for voice signals, HMM has been extensively used in various fields of voice treatment. The state dwelling distribution of normal HMM is not consistent with the actuality of the voice signals. For a given state, HMM assumes that the various frames are irrelative with each other, which also does not fit in with the reality. The fundamental cause lies in the complexity of voice signals and voice recognition. Since voice signals are a complex function affected by the physical characteristics of the speaker and the characteristics of the surrounding environment, there is huge difference between HMM/BP-based voice recognition system and the collection of voice data from different persons and from the same person at different time.

Voice recognition can be divided into two steps: the first one is “study” or “training”, and the second one is recognition. To fulfill the function of recognition, the neural network-based voice recognition system will inevitably go through the process from extracting characteristic parameter to applying recognition algorithm.

Design of the voice recognition system

The whole voice recognition system usually consists of four parts: preprocessing, characteristic parameters extraction, training and recognition. Different voice recognition system may feature different details in design and realization, yet the basic modules adopted are similar.

Preprocessing. The study mainly focus on the recognition of isolated numbers. There are not many characters for recognition, and the requirement for the adaptability to environmental noises is not demanding, as the sound recording is made in ordinary room, thus the dual-threshold end-point detection algorithm is adopted, which is quite popular nowadays, determining the beginning and end of the effective voice range according to short-time average energy and short-time zero-crossing rate of the voice signals. In addition, the limit for the lasting time of voice and the maximum time limit for silence are also set, the former used to eliminate sudden noise while the latter used to prevent miss of detection.

The voice signal input is subject to preprocessing first, including anti-aliasing filter, pre-aggravation of sound, windowed frame-targeted treatment and end point detection, etc. Pre-aggravation is to smoothen the signal and boost the high frequencies, so as to filtrate out the disturbance of low frequencies, especially power frequencies such 50Hz or 60Hz. To boost the spectrum of high frequencies which are more useful for voice recognition can make it easy for voice parameter analysis and can also eliminate DC drift, suppress random noises and boost the short-time energy of light sounds[3]. In computer, generally an one-order pre-aggravation digital filter which can boost high frequencies with 6dB/times of sound interval, as a line can be used in MATLAB to help realize this: amp=sum(abs(enframe (filter([1-0.9375],1,x),Len, Inc)),2), whereas Len is the frame length and Inc is the frame shift.

The pre-aggravation filter transfer function is:

$$H(Z)=1-0.9375Z-1 \quad (1)$$

If S(n) is the voice signal before pre-aggravation, then the signal $\tilde{S}(n)$ obtained after going through the pre-aggravation filter is:

$$\tilde{S}(n)= S(n)-0.9375\ S(n-1) \quad (2)$$

It shall be noted that when using MATLAB for voice processing, voice box is a quite useful tool box, and it needs to be downloaded from the Internet and added to the MATLAB searching route.

Extraction of characteristic parameters. The frequently used characteristics include short-time average energy and rang, short-time average zero crossing rate, linear prediction coefficient (LPC), short-time Fourier transformation and Mel frequency cepstrum coefficient (MFCC). The time sequence of voice characteristic parameter constitutes the voice pattern. Comparing it with the reference pattern extracted from a series of known signal training and the reference pattern of the optimum matching would be the recognition result.

The paper uses MFCC parameters. Before the parameters are input into the neural network, they need go through the time-regulated network, compressed after characteristically extracted and regulated into certain number of frames, To use the front-end network for time regulating is based on mainly two reasons:

First, the speed of the speaker’s speech may be inconsistent, which makes it improper to process the characteristic vector of all frames of the voice in equal weight. It is necessary to combine some characteristic vectors to make the final characteristic vector sequence consistent with the phoneme events in the voice independent of the speed of pronunciation, so as to wipe off the distortion of voice signals.

Second, to make the classification and recognition work of the neural network classifier easier, it is necessary to extract the same number of characteristic vectors for different words, and the final number of sections of the voice shall be greater than the number of phonemes contained in various words in the vocabulary list.

The simulation training adopts a BP neural network with one hidden layer. The number of the hidden layer knots is usually set according to former experience, for too many knots would make the network learning time longer while too few would make error tolerance poorer. In this example, characteristic parameter time regulating algorithm is adopted for the network, extracting a group of fixed-number characteristic vectors from the characteristic vector sequence of the voice signal input (in this paper, for each effective preprocessed voice signal segment, 12 one-order MFCC coefficient are extracted). The extraction process is as follows: using Hamming window to cut the voice into voice frames of equal length, applying positive and negative Fourier transformation on each frame, and then, after logarithm and discrete cosine transformation, picking the first 12 numbers as MFCC coefficient to describe each frame. Finally, classifying the MFCC coefficient sequence corresponding to each voice signal into four categories, assigning each voice signal with one corresponding 12 four-dimensional one-order MFCC coefficients, which will then become input signals into the neural network as characteristic parameters of the voice.

Training and recognition. Taken numbers 0～9 as the voice signal sample and 12-order Mel cepstrum coefficient as characteristic parameters, the paper uses characteristic parameter time regulation algorithm to regulate the number of frames to be four, as the input for BP network. Since the network system is non-linear, the original value has great bearing on whether learning reaches local minimum or converges. An important requirement is to try to make the state value of each neuron be close to zero when original weight values are accumulatively added in input, so as to ensure that the values do not fall onto the flat zones at the beginning. The original values of the connection weights are often picked up from random numbers, and little demanding is placed on the value of the weights, so as to ensure that each neuron is placed into where their transformation function featuring the largest gradient. And then, uniformize the input samples to enable the larger inputs to still fall into the places featuring big gradient of neuron transformation functions. The original weight is to be picked from the range of (-1,1) randomly, with a learning rate of 0.1 and an expected error of 0.01, which are subject to revision according to the experiment. The recognition results are shown in the following Table 1.

Table 1 Simulation recognition results

Samples for recognition	0	1	2	3	4	5	6	7	8	9
Times of recognition	10	10	10	10	10	10	10	10	10	10
Rate of recognition[%]	80	100	90	70	90	100	80	70	90	90
Average rate of recognition	86%									

Summary

Targeting on the recognition of the isolated words spoken out of the mouth of a non-specific person, the paper studies and constructs the BP network model and carries out simulation experiment in MATLAB. The experiment results indicate that the algorithm and software used in this paper boast high efficiency of recognition and unique advantages. However, the recognition effect would be less obvious when the quantity of experiment vocabularies increases. This is due to the fact that the BP network uses gradient descent algorithm to train the weight value, making it easy to fall to be the local minimum. Therefore, based on the above-mentioned reasons, BP network is only suitable for recognition of small quantity of vocabularies, and cannot meet the requirement for real-time voice recognition of large quantity of vocabularies.

The MapReduce Parallel Study of KNN Algorithm

Chunye Wang [1, a], Xiaofeng Zhou[1,b]

[1]College of Computer & Information HoHai University Nan Jing, P.R.China,210098

[a]wenchangyu1990@hotmail.com, [b]zhouxf@hhu.edu.cn

Keywords: Text classification; KNN algorithm; MapReduce; Text pretreatment

Abstract. Although the parallelization KNN algorithm improves the classification efficiency of the algorithm, the calculation of the parallel algorithms increases with the increasing of the training sample data scale, affecting the classification efficiency of the algorithm. Aiming at this shortage, this paper will improve the original parallelization KNN algorithm in the MapReduce model, adding the text pretreatment process to improve the classification efficiency of the algorithm.

Introduction

Text classification is a technology that can rapidly classify text information to help users locate the key technologies required for accurate information. Text classification has been concerned. It has tremendous potential and value. It has a wide range of applications as information filtering technology, base information retrieval, search engines, text databases, digital libraries and other fields.

There are many kinds of text classification algorithm, among which kNN classification algorithm are widely used, because of its simple ideas, easy to implement, high classification accuracy, etc.But kNN algorithm in the classification process, document classification needs to be calculated to the training sample set from all samples of the document, so as the dramatic increase in the amount of data, it becomes very large amount of computation, and brought the classification process is calculated too long, low efficiency of classification problems.

In response to these problems, the improved direction in our country is currently focused on achieving algorithm parallelization by transplanting stand-alone operation of the algorithm to the cloud computing platform. Wensi[2] proposed a compression algorithm based on K-nearest neighbor decision boundary, and to combine this algorithm with the cloud computing platform,using the MapReduce programming model programs; Qiao Hongxin[3] implemented the MapReduce process by improving the KNN algorithm; Hongyi Hong[4] achieved a text similarity calculation method by using MapReduce architecture; Liu Biao[5] improved KNN algorithm and proposed a MapReduce-based spatial grid index generation method; Yan Yonggang[6] added a combiner function as the transition between the map function and reduce function based on the original MapReduce model, to reduce the amount of computation KNN algorithm and so on.

The above literature shows that the algorithm classification efficiency will be influenced if the data are not processed before the classification although the parallelization KNN algorithm has largely reduced the time of classification algorithm. To solve this problem, this paper is based on the literature[6] and designs a pretreatment process to improve the classification efficiency.

The Parallel Design of KNN Algorithm

The Basic Idea. In this paper, the basic steps to parallelize KNN algorithm is as follows:
The first, text preprocessing stage.

First, Worker nodes download the training sample and test sample from the HDFS system file to the local node, then pretreate the training sample and the test sample. The map nodes will implement some processes, such as word segmentation and stopping words. Then implement the Reduce process. The documents which are in the same class will be together and output to the file system HDFS.

The second, text classification stage.

The input of the stage is the output of the previous stage. Map nodes read the input data to calculate the similarity between the test samples and the training samples. Then the combiner function mergers the output of several Map nodes and takes the first k- nearest neighbors. The several k- nearest neighbors will be sorted by similarity in the Reduce. Electe pre-k nearest neighbors as the final k neighbors and calculate the weight, and finally conclude output.

To fit MapReduce computation model, the data which will be treated is stored in rows before the Map operation. Specific operation is performed on the data by row slice, requiring inter-chip unrelated data, and default slicing operation is done automatically by the MapReduce.

Text Preprocessing Stage. All the training sample datas need to be pretreated before the text classification. The basic two steps of the pretreatment process is word segmentation and stopping words. Stopping the words refers to remove the semantic virtual pan-word, such as "of", "the" in English. Generally, disable vocabulary which is summarized is used to remove the stop words before the text pretreatment process[7]. The text preprocessing phase flow chart is be shown in Fig.1.

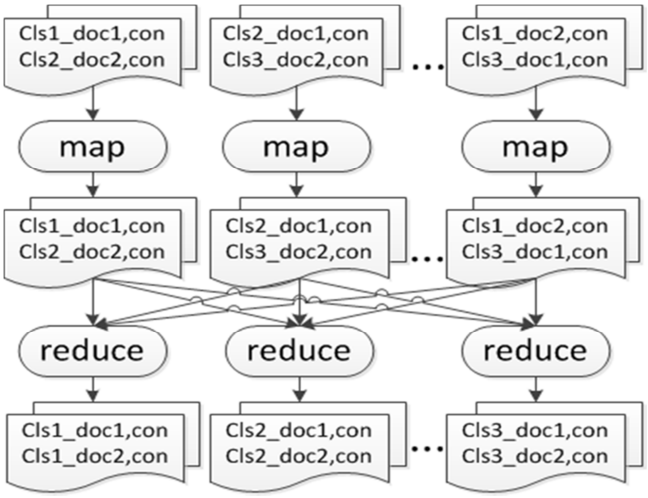

Fig.1 Text preprocessing phase flow chart

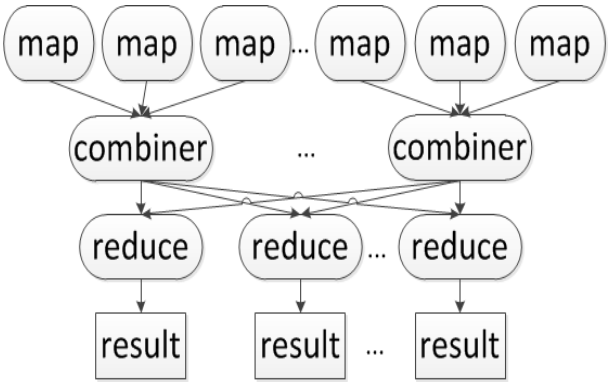

Fig.2 Text classification stage flow chart

(1) Map stage

The task of the Map stage is sending the disable vocabulary to each Map nodes for segmentation and removing the stop words by distributed cache. The result will be the input of the next stage.

Algorithm1.

```
public ListWritable Map(int RateTermKey){
    FileReader fr=new
    FileReader("D:\\StopWordList.txt");
    BufferedReader br=new BufferedReader(fr);
    String s = "";
    while(br.readLine()!=null){
        s += br.readLine();}
    br.close();
    ListWritable lw = new ListWritable();
    for(int i=0;i<RateTermKey; i++){
          String content = ReadFile(RateTermKey);
          lw = Segment(content);
          lw = TermFreq(lw);
          lw = StopWFilter(lw,s);
          Write(RateTermKey, lw);}
    return lw;}
```

Algorithm2.

```
public ListWritable Reduce(int
RateTermKey){
    ListWritable lw = new ListWritable();
    for(int i=0; i<RateTermKey; i++){
    EmitIntermediate(i, lw);
    Write(RateTermKey, lw);}
    return lw;}
```

First, the Map nodes read the text collection and converted the format of the input document into key-value pairs<class _ document, contents>. Then text collection will be implemented the word

segmentation and stopping words processes in accordance with the rules of the function. The form of the result which is the same as the form of the input will be passed to the next nodes of Reduce stage. Map function algorithm is shown in algorithm1.

(2) Reduce stage

The output datas of the Map stage is as the input of the Reduce stage after being reshuffled. The task of the Reduce stage is to have the same type of document composition together and output to HDFS file system, so their forms are the same. Reduce function algorithm is shown in algorithm2.

Text Classification Stage. Text classification stage flow chart shown in Fig.2.

(1) Map stage

The task of the Map stage is to read the training sample sets and test sample sets and to calculate the similarity between them. First, invoke built-in Split functions, read samples and convert them to files whose format to be determined by line. Then the Map nodes traversal each test sample to calculate the similarity with the training samples. Finally, the result will be collected into context. The form of the input data is <category, list <document, contents >>. The form of the output data is <category, list <document similarity values>>.Map function algorithm is shown in algorithm3.

Algorithm3.

```
public ListWritable Map (int RateTermKey){
for(int i = 0; i< training dataset; i++){
RateTermKey = FindCatalog(i);}
for(int k = 0; k <testfile; k++){
Distance = EnclideanDistance(k,i);
Context.write(RateTermKey, vector(RateTermKey,Distance));}
return vector;}
```

Algorithm4.

```
public vector combiner(int RateTermKey){
for(int i = 0; i < training dataset; i++){
ArrayList.add(vector(RateTermKey,Distance));
Sort(ArrayList);
Context.write(RateTermKey, ArrayList.get(k)); }
return ArrayList.get(k);}
```

Algorithm5.

```
public vector Reduce(int RateTermKey){
for(int i = 0; i < RateTermKey; i ++){
ArrayList(vector(RateTermKey, ListWritable));
Sort(ArrayList);
result = Sort(ArrayList);
result.add(RateTermKey, ArrayList.get(k));
Context.write(RateTermKey, Tradition KNN(result));}
return result;}
```

(2) Combiner stage

The task of the combiner stage is to merge several Map nodes. Then find out the first k-nearest neighbors. The number of the combiner nodes is far less than the number of Map nodes and its purpose is to filter the neighbor samples in advance and reduce the computation of the Reduce nodes.Combiner function algorithm is shown in algorithm4.

(3) Reduce stage

Reduce stage is implement the statute operation. The task is collecting and sorting the weights of the several k neighbors by similarity. Then the Reduce nodes elect the first k-nearest neighbors as the final k-nearest neighbors, calculate their weights and sum the weights of the samples whose categories are the same. The category of the test sample is the category which belongs to the samples of the maximum summing. Reduce function algorithm is shown in algorithm5.

Algorithm Analysis. In the MapReduce programming model, the training sample sets and test sample sets are stored in HDFS file system, then the data will be divided into a plurality of data blocks to assign to each node to implement pretreatment and classification. There is only a For loop function during the text preprocessing stage. It doesn't involve too much calculation. The largest part of the calculation amount is the process of calculating the sample similarity. But the calculation is assigned to a plurality of nodes to treatment because of the parallelization. Therefore, if the scale of the parallelization nodes is **p**, its time complexity is: $\boldsymbol{O(ns)/p}$, where **n** is the total number of training samples, **s** is the number of characteristic attributes.

KNN algorithm one time reads all samples into memory because of its inertia. So the traditional KNN space complexity is linear with the number of samples. It's $O(n)$, where n is the number of

samples. When p nodes participate KNN classification, the total samples are to be allocated to p nodes regardless of how many blocks the data sample is divided into. So the space complexity of the algorithm is $O(n)/p$.

Experiments and Results Analysis

Experimental Environment to Build. In this experiment, 8 machines are used to build a cloud computing platform. One of the servers is a master node of the distributed file system HDFS. It's used to manage other worker nodes. The other seven machines are the work nodes of HDFS. They are used to run MapReduce tasks. The configuration of the cluster is the official website of the recommended ways to build.

Experimental Design and Analysis of Experimental Results. This experiment is testing the KNN algorithm in the cloud computing environment and comparing the efficiency with the unmodified algorithm.

In the experiment, the data is selected from the UCI Machine Learning Repository, which is based on geological variables to predict forest vegetation covering types. These geological variables are with some authority from USGS (United States Geological Survey) and USFS (United States Forest Service). The data set has 581,012 samples, of which there are 387,342 training samples, 183 671 test samples [2].

First test and verify the accuracy and recall rates of the parallelization KNN algorithm. In the experiment, 4 data sets are selected as the test data sets ,ie T1 ~ T4. Their basic information are shown in Table.1.

Table.1 The comparison of algorithm parameters in both cases

Dataset	Sample Number	Sample Characteristic Propertie Number	Accuracy		Recall Rate	
			Before Improvement [%]	After Improvement [%]	Before Improvement [%]	After Improvement [%]
T1	10,000	2000	86.9	86.9	84.3	84.3
T2	20,000	2000	85.4	85.4	83.7	83.7
T3	30,000	3000	90.5	90.5	82.5	82.5
T4	40,000	3000	89.2	89.2	83.1	83.1

As we can also see from Table 1, the accuracy and recall rates of the former algorithm are the same as the later one. It explains that there is no impact on the classification results after pretreating the parallelization KNN algorithm and it doesn't reduce the accuracy of classification.

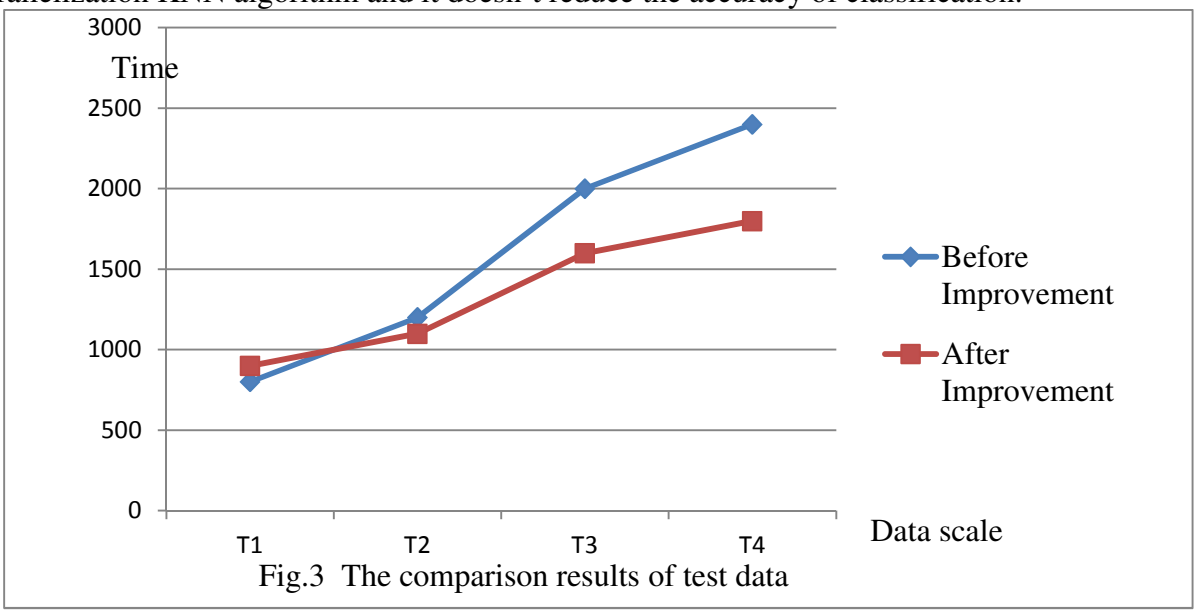

Fig.3 The comparison results of test data

As we can see from Fig.3, the execution time of the algorithm is constantly increasing with the increase of the data size. When data is smaller (T1), the execution time of the former algorithm is less

than the later one and it doesn't reflect the advantages of preprocessing. The mainly as follows: For the MapReduce model, it takes some time for the nodes to call the function to perform tasks and interact. Especially when the data size is small and the actual calculation is in a small proportion of the total task time, this phenomenon is particularly evident. When the scale of the data is increasing, the execution time of improved algorithm is gradually less than the time of the former one, which shows that the pre-processed data has a significant effect on improving the efficiency of KNN classification algorithm.

Conclusion

This paper improves the original parallelization KNN classification algorithm. We add the text pretreatment process before the classification process of the KNN algorithm. Through comparison and analysis of the experiments, we can conclude that the improved algorithm has a role in improving the efficiency of classification algorithm.

Keywords: Software security, Software structural stability, Complex networks, Motif

Abstract. The issue on finding an effective evaluation method on software structural stability is rarely touched upon in software security research. An assessment method of software microstructural stability was developed by Khalil in 2002. A new evaluation method on software structural stability is proposed in this paper, which is based on Motifs according to the theory of complex networks. Average shortest path length comparison and clustering coefficient with degree distribution are used in the method, in which the key evaluation indexes are used to analyze software structural stability. The comparison experiments have been done between the proposed method and Khalil's method. 10 real software systems of different sizes and types are selected in the experiments to verify the proposed evaluation method. The result shows that the proposed method is correct and effective.

Introduction

Software reliability factors have been taken into account in software security area now. Software reliability is the ability of software that allows it to continue to run properly under malicious attacks. This kind of ability can be measured. Trivedi [1] believed that there are mainly nine factors affecting software reliability. Among all of them, software structure is the most important and the most direct one.

The theory of complex networks has a strong interdisciplinary characteristic, involving many fields, such as mathematics, statistics, physics, ecology, sociology and economics. Complex networks research also involves several kinds of networks, such as biology networks [2] (cell networks, protein - protein role of the networks, protein folding networks, neural networks, ecological networks, etc..), Internet/WWW networks and social networks [3] (scientists cooperation network, relations network, linguistics networks, etc.). Studies have confirmed that the phenomenon of complex networks exists in large software systems, and software system topology is also manifested in the form of a network. Software system functionality, performance, and stability will be largely affected by the topology of the software.

A new software structural stability evaluation method based on Motifs is proposed in this paper. There are some experiments that have been done to measure how software structural stability is impacted by Motifs and what factors will affect software structural stability. Research work what has been done in this paper will be a great significance for software system maintenance, evolution and reconstruction.

Research

Software microstructural stability research. Software microstructural stability is provided as a method by Khalil [4].In Khalili's method, the network SSS is calculated, which will be used to measure the software microstructural stability [5]. Lyapunov exponent [6] is used, and the Jacobian matrix eigenvalues must also be calculated. That is following formula (Eq.1, Eq.2):

$$J = \{a_{ij}\} = \{\frac{\partial f_i}{\partial x_j}\} \quad (1)$$

$$\dot{x}_i = f_i(x_1, \ldots\ldots, x_n) \quad (2)$$

Eq.2 is differential equations of dynamic systems. If use a_{ij} represent the impact (symbols and weights) from node j to node i, then the Jacobian matrix can be used to represent the connectivity of the local structure; further, if normalized a_{ij} to 0 or 1, then Jacobian matrix can be reduced to the corresponding adjacency matrix. For a software system, its self-interaction can be considered that the impact of its own node is inactive. Then the corresponding Jacobian matrix diagonal a_{ij} is negative.

Meantime, root-locus [7] method is used to calculate the eigenvalues of the entire matrix, which determine whether the system is stable or oscillate. The proportion of eigenvalues is negative real numbers representing the SSS. For directed graph without cyclic structure, SSS=1 can illustrate the structural stability has nothing to do with parameter; When increasing the number and size of cyclic structure, feedback loop J consisting of nodes changes, SSS≈0.5 can illustrate the software structure is not stable. The conclusion proposed by Kahalil is consistent with some of the basic principles: Loop structure should be avoid in the design of software systems, otherwise it will increase the software complexity and reduce the software structural stability.

Motif and network stability research. With self-organization, self-similar, attractor, small-world, scale-free, some or all of the network properties are known as the complex networks.

Typically, the network element contains far more than three elements, thus those can form lots of networks. In recent years, through analyzing real network researchers found that these relationships were occurred in non-randomness, and they had formed some typical network connections. That is, different types of network having different typical connections. The number of occurrences in the real system is much higher than the number of random networks recurring. Milo called this element interconnection pattern (or unicom subgraph) Motif [8], and this basic structure of the network is considered "brick", used to implement some of the key features.

Despite the structure of complex networks is complicated, but the way and the process forming complex networks has a certain law. From the point of arrangement, there are a maximum of two kinds of relationships between two elements, and 13 different relationships can be formed in three elements. 3 nodes Motifs have their own id (are shown in Fig.1).

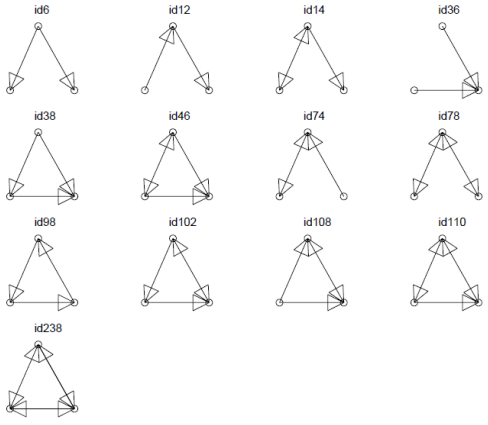

Fig.1 3 nodes Motifs

The stability of complex networks has become an important research content in the complex networks area. For the study on the stability of complex networks, predecessors demonstrated the scale-free networks in details [9], random network of anti-perturbation capability [10]. They made a great contribution to the stability of complex networks. They thought that attacking the networks can be in two ways :break the nodes and break the edges [11].The two ways of attacking are random attack and selective attack which are called network fault-tolerance and network anti-attack capability.

Chinese scientists had a great progress in the study of the stability of complex networks. Statistical physics methods [12], Monte Carlo method [13], random fluctuations method [14], etc. are all applied

in the study. In this paper, a method of software structural stability evaluation based on the Motifs is proposed, which had been used in network stability reseach.

Software structural stability evaluation method

Overview. For the study on complex networks characteristics of software systems, the key step is using open sources software and taking a "reverse engineering" approach. Depending on the granularity of units, the software system can be seen as different modules, classes, methods of the class consisting of, etc.. This paper follows the "reverse engineering" approach to abstract the software structure, select Motifs, and then analyze the experimental data using the shortest path length comparison and clustering coefficient with degree distribution method. Flowchart is shown in Fig.2.

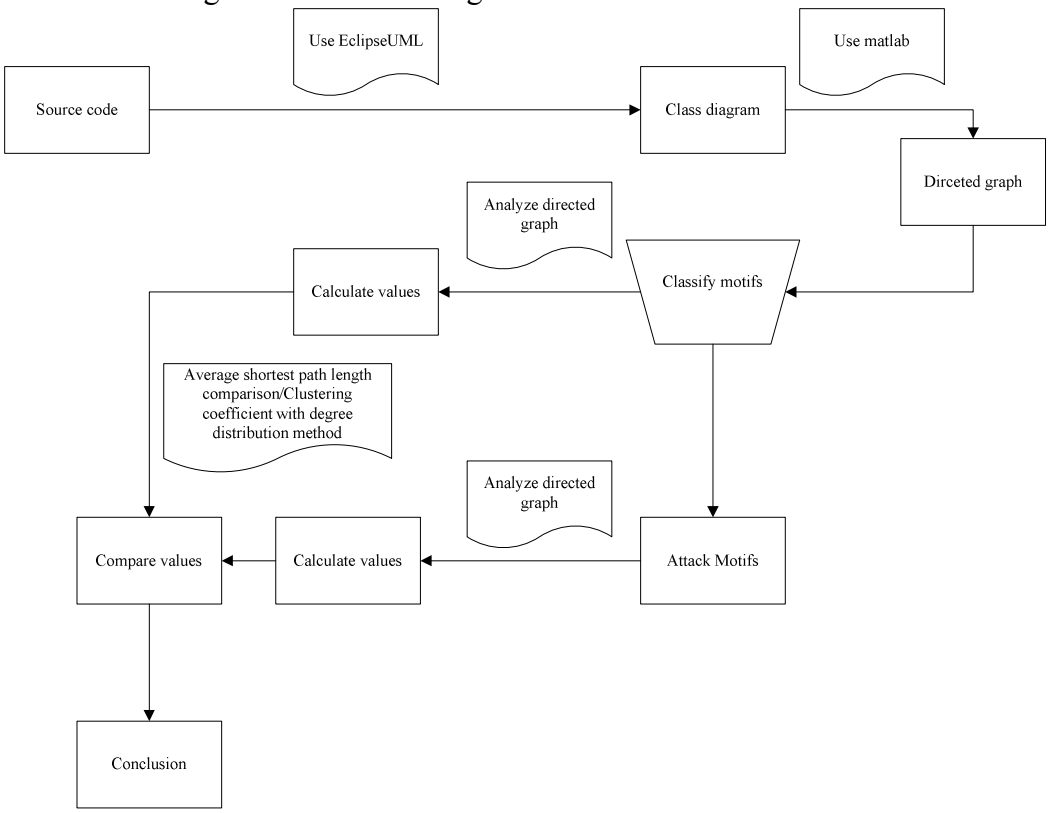

Fig.2 Method flowchart

Steps. Based on the flowchart in Fig.2, describ the specific steps below.

Step 1:Abstract the software structure: using the Eclipse UML software, put the source codes and turn into class diagram. If there are some bugs in class diagram, manual correction must be done. And write the Matlab codes, put class diagram into the *pajek* softare with the form of connection table. Class diagram will be changed into a directed graph in *pajek* software. In the directed graph the node represents class and the edge represents the relation between class and class.

Step 2: Classify Motifs: classify all of Motifs into 3 categories: no cyclic structure, less than or equal 2 nodes cyclic structure and greater than 2 nodes cyclic structure.

Step 3: Calculate the original index values (average shortest path length, clustering coefficient, degree distribution, etc.):

(1)Average shortest path length: is a concept in network topology. It is defined as the average number of steps along the shortest paths for all possible pairs of network nodes. It is a measure of the efficiency of information or mass transport on a network. L value is shown in Eq.3.

$$L = \frac{1}{\frac{1}{2}N(\mathrm{N}-1)}\sum_{i>j} d_{ij} \tag{3}$$

(2) Clustering coefficient: is a measure of the degree. Nodes in a graph tend to cluster together. Evidence suggests that in most real-world networks, and in particular social networks, nodes tend to

create tightly knit groups characterised by a relatively high density of ties; this likelihood tends to be greater than the average probability of a tie randomly established between two nodes. C value is shown in Eq.4.

$$C_i = \frac{2E_i}{k_i(k_i - 1)} \tag{4}$$

(3) Degree distribution: The degree of a node in a network (sometimes referred to incorrectly as the connectivity) is the number of connections or edges the node has to other nodes. If a network is directed, it means that edges point in one direction from one node to another node, then nodes have two different degrees, the in-degree, which is the number of incoming edges, and the out-degree, which is the number of outgoing edges.

Step 4: Attack Motifs, calculate values, and then analyze changes.

Classify Motifs. The proposed method based on Motifs in this paper focuses on the intrinsically linked and the structure affected between nodes and nodes, and the inherent linked mode on precisely structure for software structural stability is crucial**.** Classify all Motifs into 3 categories: no cyclic structure, less than or equal 2 nodes cyclic structure and greater than 2 nodes cyclic structure. For 3 nodes Motifs whose ids are based on the Fig.1: Category 1: Motif ids are 6, 12, 36, 38; Category 2: Motif ids are 14, 46, 74, 108; Category 3: Motif ids are 78, 98, 110 and 238.

Analysis. The average shortest path length comparison and clustering coefficient with degree distribution is applied in the proposed method. They are different from the previous analysis method. The proposed method in this paper focuses on the differences between the value and the rate of change, which can fully reflect the condition of software system after the destruction of the case and before the damage assessment.

(1)Average shortest path length comparison method: The average shortest path length L is divided into two cases, L value is increased after attacked, which means that damage to the nodes has little effect; L value decreased after attacked, calculate the change in the difference $L_{DV}=L_{AT}-L_{ST}$, the rate of change $P_L=L_{DV}/L_{ST}$, and analyze the impact on the structural stability based on the rate of change.

(2) Clustering coefficient with degree distribution method: Clustering coefficient C is divided into two cases. One C value is increased after attacked, which means that damage to the nodes to have little effect; the other C value decreased after attacked. Calculate the change in the difference $C_{DV}=C_{AT}-C_{ST,}$ the rate of change $P_C=C_{AT}/C_{ST,}$ and analyze the impact on the structural stability based on the rate of change.

Some state values changed will be get based on the above two methods, according to the principles of the complex networks metrics. Through this kind of analysis method, a conclusion can be claimed that the Motifs structure tends to simple, interactive elements bound tends to evacuate, and then the software will tends to stable. The Motifs with cyclic structure affect the structural stability greatly.

Experiments and result analysis

Based on the above experimental steps and methods, select a software called *openwfe* (A small daily office management system by JAVA), and conduct the experiment.

Step 1: Abstract the *openwfe* from source codes to class diagrams, and converted class diagrams into a directed graph. The graph is shown in Fig.3 and Fig.4.

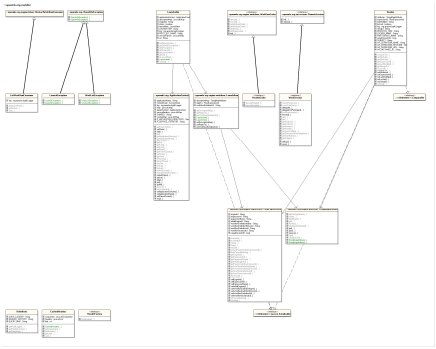

Fig.3 Class diagram

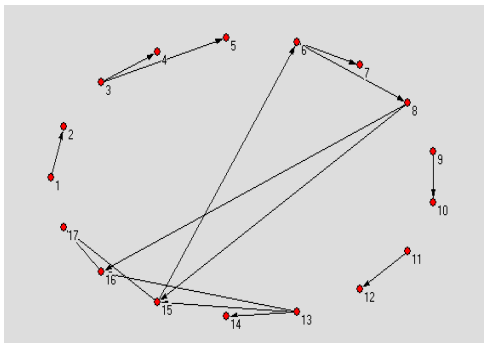

Fig.4 Directed graph

Step 2: Classify Motifs based on the method which has been introduced in Section Classify Motifs.

Step 3: Calculate the original index values, the process is shown in Fig.5, Fig.6, Fig.7, Fig.8 and Fig.9

Step 4: Attack different Motifs , calculate values, and compare values. Experiment results are shown in Table.1.

Table.1 Experiment results

Motif Catagory	Motif id	L_{ST}	C_{ST}	L_{DE}	C_{DE}	P_L	P_C
1	6	1.64	0.0595	1.58	0.0323	0.036585	0.457143
1	12	1.64	0.0595	1.53	0.0343	0.067073	0.423529
2	14	1.64	0.0595	1.49	0.0258	0.091463	0.566387
1	36	1.64	0.0595	1.54	0.0312	0.060976	0.47563
1	38	1.64	0.0595	1.51	0.0243	0.079268	0.591597
2	46	1.64	0.0595	1.44	0.0210	0.121951	0.647059
2	74	1.64	0.0595	1.50	0.0321	0.085366	0.460504
3	78	1.64	0.0595	1.49	0.0254	0.091463	0.573109
3	98	1.64	0.0595	1.43	0.0220	0.128049	0.630252
3	102	1.64	0.0595	1.42	0.0211	0.134146	0.645378
2	108	1.64	0.0595	1.45	0.0229	0.115854	0.615126
3	110	1.64	0.0595	1.41	0.0199	0.140244	0.665546
3	238	1.64	0.0595	1.40	0.0167	0.146341	0.719328

Experiment Analysis: The statistics shows that, Motif id 6,12,36,38 do not exist cyclic structure, P_L values after the attack are relatively small, and relatively large id after the attack, P_L values are relatively large, nearly 15%. For a module of a software system, attack a small portion of the structure, make the parameters change rate of up to 10%, or even higher, thus this Motif has great effection on the structural stability. The Motif whose rate of change is relatively small, has less effection on the structural stability. That is, the Motif id more larger, the software more unstable.

Motif id 46,98,102,110 and 238, L values change rate are over 10% after attack, C values change rate are over 50%. They have a greater impact on the software system structure, thus they affect the stability of the software. A conclusion can be found that all of the Motifs have one common characteristic,that is, one or more cyclic structure existed in Motifs. Again, campare Motif id 108 with Motif id 98, despite Motif id 108 has one more edge, but the presence of a cyclic structure participation points less than Motif id 98. It shows that in the software system structure, if the cyclic structure is attacked, the software system structure will be affected greatly, and the more cyclic structure in nodes, the more affection in structure.

To verify the above assumptions, 10 different size, types and real software systems (module type definitions 60) are chosen to do experiments using the proposed evaluation method in this paper. In the experiments we can see that if a cyclic structure is present in the attacked Motif, P_L values will be maintain a high level on or, worse value may be greater than 20%. Without the presence of cyclic structure after Motif attacked P_L values are maintained at a very low level, and the data is consistent with the conclusions obtained to verify the correctness of the above result.

To verify the model and conclusion, the comparison experiments have been done using Khalil's method. SSS values of different Motifs are shown in Table.2.

Table.2 SSS values of different Motifs

Motif Catagory	Motif id	SSS
1	6	1
1	12	1
2	14	≈0.5
1	36	1
1	38	1
2	46	≈0.5
2	74	≈0.5
3	78	＜0.2
3	98	＜0.2
3	102	＜0.2
2	108	≈0.5
3	110	＜0.2
3	238	＜0.2

Khalil's method in accordance with the conclusions, SSS = 1 indicates strong structural stability, SSS ≈ 0.5 indicates relatively poor structural stability, while SSS <0.2 indicates poor structural stability. Thus, the same conclusion can be get from the proposed method in this paper and Khalil's method. Stability is connection with the feedback loop gain of subgraph. If there is a cyclic structure or the number of cyclic structures is increased, the stability of the system will decrease. Therefore, the process of coding software in the future, we should try to avoid cyclic structures in our design to ensure greater stability of the software.

Conclusion

In this paper, we proposed a software stability assessment method, according to network reliability research method for complex networks.The essential idea of this method is that software structure can be divided to different Motifs, and then the structural stability can be evaluated through Motifs attack.

Evaluation indexes are proposed in this paper, which are calculated by the average shortest path length comparison method and clustering coefficient with degree distribution method. 10 different real software systems of different sizes and types including various modules (module type definitions 60) were selected to do comparison experiments between the proposed method and the software microstructural stability assessment method given by Khalil. The result shows that the proposal method is feasible and correct.

According to the research what have been done in this paper, some suggestion should be given that simple structures, evacuation constraints, and low cyclic structures will be better in the design of software. Otherwise the complexity of the software system will be increased and the software structural stability will be reduced.

Further research work is how to estimate and metric the price of the different Motifs in software structure stability area.

Keywords：Character 2D barcode; Cross method; Mathematical morphology; Shape angle

Abstract. This paper studies the locating method for character 2D barcode. In this kind of character 2d barcode, the solid circle is designed as the position detection patterns. The locating method for character 2D barcode is different with the traditional method for DM barcode. In this paper, according to the geometric characteristics of the solid circle, connected region regarded as suspected solid circle can be filtered through the cross method rapidly. Then the edge of connected area is detected through the shape angle and the solid circle can be found through the circularity values. Experiment results show that this method can locate the character 2D barcode rapidly and effectively.

Introduction

Traditional Data Matrix 2D barcode takes the “L” shape as the position detection pattern and the QR barcode takes the black box as the position detection pattern. In this paper, the character 2D barcode takes the solid circle as the locator. The Fig. 1 shows the three kinds of barcodes.

Fig. 1 Three kinds of position detection patterns in barcodes

In this paper, we propose a new locating method for the character 2D barcode. For the barcode image gotten, we can segment the barcode image from the background using the segmentation algorithm combing the global and local thresholding algorithm firstly[1]. Then the homomorphic filtering method is used to remove the noise. So we can get the character 2D barcode image.

Filtering connected region through the cross method

In order to locate the character 2D barcode, the solid circle should be located. In this paper, we filter the connected region through geometric characteristics in order to filter those obviously irregular connectivity regions[2][3].

Here, we use the cross method to get the circle center and get the connected region through the circle center. The principle of the cross method is based on the fact that the distance from the center point to the points on the edge is equal. So if the distances from a point to the left, right, upper, and lower edges are equal, or these four distance differences are within a threshold ω, the point can be regarded as center point. The connected regions gotten from this method will always include some character connected regions and some background connected regions. But the ratio of height and width for the character connected region is 3:2 usually and the ratio of height and width for the solid circle region is 1:1. Because there is some deformation in the character 2D barcode image, the solid circle will always become a solid oval. So in our experiments, we find if the ratio of height and width is set within the range of [0.8,1.2.], the solid circle can be filtered better. It is showed in Eq.1.

$$H(R_i):W(R_i)<=1.2\&\&H(R_i):W(R_i)>=0.8 \tag{1}$$

Here, R_i is the i-th connected region. $H(R_i)$ is the height of the connected region and $W(R_i)$ is the width of the connected region.

Detecting solid circle through shape angle

Based on this filtering method, some suspected connected regions can be detected. Then the shape angles can be calculated to determine solid circle. The shape angle can be defined in Eq.2.

$$D_\alpha = \frac{1}{n}\sum_{i=0}^{n-1}\alpha_i = \frac{1}{n}\sum_{i=0}^{n-1}\arccos(\overline{g_i},\overline{m_i}) \tag{2}$$

Here, the $\overline{m_i}$ is the connection line between the point on the geometric contour and the geometry centroid. The $\overline{g_i}$ is the corresponding normal vector of the point. The angle between these two lines is defined as α_i.In a closed graph, the average of corresponding α_i of all points on the contour is the shape angle D_α. For the perfect circle, the D_α is zero. We can determine a connected region as a circle when its D_α is less ε. Here, ε is equal to π/6.

Locating solid circle through circularity value

Traditional edge detection methods include first-order differential operator and second-order differential operators, such as Roberts operator, Sobel operator, Prewitt operator and Kirsch operator, etc. belong to the first-order differential operator. The classic second-order differential operators have Laplacian operator, LOG operator and so on[4]. These operators can be implemented easily, but they are sensitive to noise.

In this paper, we use mathematical morphology method to get the edge[5]. Mathematical morphology is a nonlinear mathematical method evolved from set theory. The basic idea is to use the interaction between collection of image shapes and the structural elements selected in order to recognize and analyze the images. The method is not sensitive to the noise.

Basic mathematical morphology operations include: erosion, dilation, opening, closing, etc., where erosion and dilation are the two most important basic operations, others are transformed by the these two transformation combination of these two operation.

In the morphology, the operation object is a collection. Assuming that X is a collection of image, B is the structural element, a regular expression is that X operates on B, The operator "Θ" is taken as erosion operator. Arithmetic erosion expression is defined in Eq.3.

$$X\Theta B = \{a \mid B_a \subseteq X\} \tag{3}$$

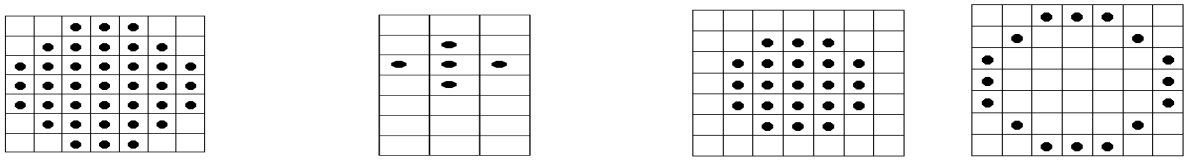
In which, the structural elements B is translated α to get B_α. If B_α is included in the X, then the α is marked. All points that satisfy the above conditions is the result of the $X\Theta B$.

We use anti-erosion computing operation to extract the edge of connected region. The operator "$\overline{\Theta}$ " is taken as anti-erosion operator. The anti-erosion expression is defined in Eq.4:

$$X\overline{\Theta}B = \{a \mid B_a \not\subset X\} \tag{4}$$

In which, the structural elements B is translated α to get B_α. If B_α is not included in the X, then the α is marked. All points that satisfy the above conditions is the result of the $X\overline{\Theta}B$.

Generally, common structural element can be a cross-shaped, or square, or linear and so on. The structural element is actually a small window of gray scale "morphology " . In this paper, the cross structure element will be selected to operate the round connected region. The erosion operating and the anti-erosion operating results are showed in the Fig. 2.



(a) Round connected region X (b) Cross structure element B (c) $X\Theta B$ (d) $X\overline{\Theta}B$

Fig. 2 Edge detecting based on anti-erosion operation

Based on the anti-erosion operation, the edge of round connected region can be detected. Then we can count the number of points in the connected region to get the area S_i. Using the formula of circularity value, we can get the circularity value of each round connected region. It is defined in Eq.5.

$$T_i = 4\pi * S_i / L_i^2 \tag{5}$$

If the number of round connected region is bigger than three, we can sort the suspected round connected regions by their circularity value. The first three greatest values are corresponding to the target solid circles.

Calculating the fourth solid circle

After locating the three solid circles, we will calculate the corresponding centers of the three solid circles. Here, the center coordinates and radius of the circle are used to determine the range of character barcode region. Assuming coordinates of solid circle centers are (x_i, y_i) and r_i is the radius of the i-th solid circle. They are defined in Eq.6-Eq.8.

$$x_i = \frac{1}{A_i} \sum_{x_i \in R_i} R_i . x_i \tag{6}$$

$$y_i = \frac{1}{A_i} \sum_{y_i \in R_i} R_i . y_i \tag{7}$$

$$r_i = \sqrt{A_i / \pi} \tag{8}$$

In which, the A_i is the i-th area of the solid circle and R_i is the i-th solid circle connected region. We can calculate the center coordinates of fourth solid circle according to the center coordinates of three solid circles based on the geometric symmetry principle. They are defined in Eq.9 and Eq.10.

$$x_{D1} = x_{A1} - x_{B1} + x_{C1} \tag{9}$$

$$y_{D1} = y_{A1} - y_{B1} + y_{C1} \tag{10}$$

Here, the coordinates of (X_{A1},Y_{A1}), (X_{B1},Y_{B1}), (X_{C1},Y_{C1}) are the center coordinates of the three solid circle. The (X_{D1},Y_{D1}) is the fourth center coordinate. The figure 3 is the locating process of the fourth solid circle.

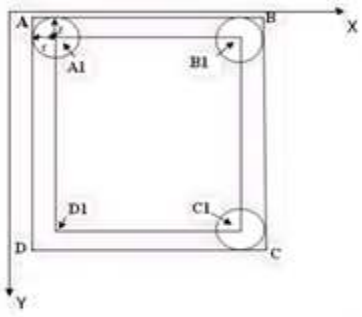


Fig. 3 Locating the four solid circles

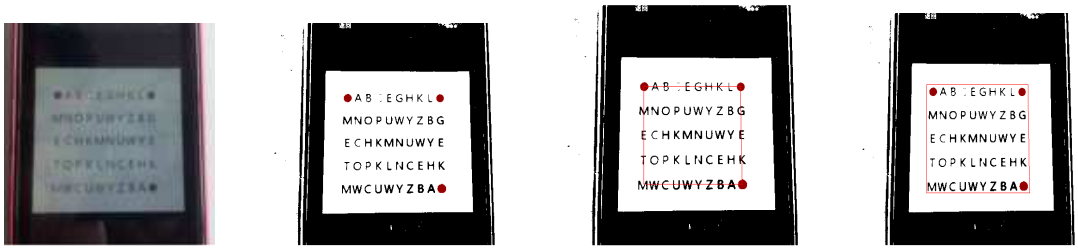
So the original character 2D barcode image will be located based on the above method. The Fig. 4 shows a case of locating an image.



(a) The original image (b) Locating the three solid circles (c) Calculating center (d) Locating the barcode

Fig. 4 Locating process of the character 2D barcode

Conclusions

In this paper, we use cross method to filter the connected region in order to detect the suspected position detection patterns-solid circles. Then through circularity value, we locate the solid circles. Finally, the coordinates of fourth solid circle can be calculated and the barcode can be located. The experimental results show that this method not only faster, but also has better stability and robustness.

Abstract. Fractal technology can simulate the growth of trees very well.There have been many research on using fractal theory to model trees,but most methods have not further explore the tree's natural phenomena such as swinging driven by wind Firstly, this paper gave a modeling method to generate the trees based on the three-dimensional fractal L system; Secondly, according to the hierarchy of the strength characteristics of the wind and trees progression, this paper also gave the wind model to simulate the natural wind farm.In the end , this paper made some simulation about the model of "Wind- Blowing & Tree- Swing and Leaves-Falling & Braches- Broken" .

Introduction

Fractal Simulation of 3D Trees

Introduction to L-System. L-systems were introduced by A. Lindenmayer as a mathematical formalism for modeling multi-cellular organisms that form linear or branching _laments. The whole organism is treated as an assembly of discrete units, called modules. The nature of the modules is not predened by the formalism. For example, they may represent individual cells in the models of lower organisms, or functional units, such as apical meristems, internodes, leaves and owners, in the models of higher plants. Each module is represented by a symbol (a letter of the L-system alphabet), which species the module's type.

Fractal Simulation of Trunks. Generally speaking, L-system is used to represent a triple tree model constructed required, namely $L =< w, v, p >$, where V is a set of characters, letters and special symbols; w is V character described in the initial state of the tree model; P is the set of rules for tree growth.

By observing the growth of trees， we will find that the growth process of trees is a few sprigs stems grow to four weeks, most small to give birth to some of the smaller branches and twigs, and so forth down, and did not end in the most branches grown on the leaves of a similar shape of the process. Therefore, regardless of the growth rules of different trees, they all can be abstracted by two elements: the branches and leaves.

Therefore, in this paper we used cylindrical depicted in the branches and trunks of every short, while the size of cylindrical cross-section is obtained from the following equation measured by the Murray method:

$$\gamma_0^P = \gamma_1^P + \gamma_2^P, p \in [2.49,3.00] \quad (1)$$

From formula (1)we can learn that : the greater of P the greater of the tree.Where, r_0, r_1, r_2 respectively represent the radius values of mother branches and its' sub-branches (shown in Fig.1).

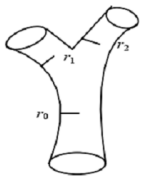

Fig 1. The relationship of the value of collateral radius and its mother branches

Simulation of Leaves As for the simulation of leaves, shell finite element analysis method is adopted. In finite element,shell element is one dimensional size that is far less than the scale of the other direction , and the stress perpendicular to the one dimensional scale can be ignored. Shell element edge is usually used in the finite element model to form, and it can be treated as a two dimensional entity from the side.which is shown in Fig 2.

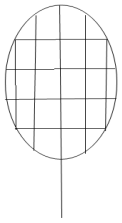

Fig-2. The Shell Element

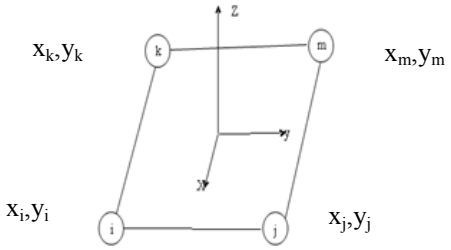

Fig -3. The Coordinated of Shell Element

Every node of shell element has six degrees of freedom,the coordinates are: $(x_i, y_i), (x_j, y_j), (x_m, y_m), (x_k, y_k)$,in the finite element method in displacement mode unit using polynomial approximation as a function, because the polynomial arithmetic is simple, and with the increase in the number of items that can approximate any function for some smooth curve.

Simulation of Wind Power. Simulation of wind power uses perlin noise function.The function was proposed by Perlin K in 1985.Its essence is a random number generator.But different from normal random number generator,it uses an integer as a parameter,and then returns to a random number based on the parameter.If the same parameter is passed twice the same random number will be produced.

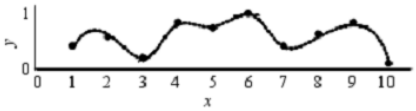

Fig -4 An Example of Noise Function

Fig-5 is an example of a noise function.Dark spots stand for the random number of the domain of function.Continuous noise function in figure 2 is formed by smooth interpolation (such as linear interpolation, three times of interpolation, etc.) of dark spots.When add some continuous smooth function of different frequency and amplitude together,a new Perlin noise function can be gotten

Motion Model of Leaves Falling and Branches Folding

Principle Model of Leaves Falling.

When you create the tree model with leaves and branches, we usually take follow steps. In order to study when the leaves fall, we give each leaf an attribute item $F_{i,thresthold}$, which is to represent the leafi can withstand the most vigorous.The value of $F_{i,thresthold}$ uses the following formula.

$$F_{i,threshold} = F_{constant} + \alpha \bullet F_{noise} \quad (2)$$

Where, $F_{constant}$ is a constant. Its resultant force can be adjusted according to the simulation results in combination with the force of leaves and its minimum value can be zero; F_{noise} is the value generated by Perlin noise.As a adjustment coefficient, α can be adjusted according to simulation

results.Each leaf threshold $F_{i,threshold}$ is determined, and we can calculate the current force that the leaves suffering,F. Comparing F with $F_{i,threshold}$, if F> $F_{i,threshold}$, the leaves will fall down,Otherwise, the leaves will follow the original manner..

When the leaves fall, they will no longer be restricted by the petioles. Leaves are affected by the gravity, the wind and air friction during their falling down process . Meanwhile, in order to make the leaves falling movement is more natural, a noise power F_{noise} is added. Force analysis of leaves in the falling process of leaves is shown in Fig-6.

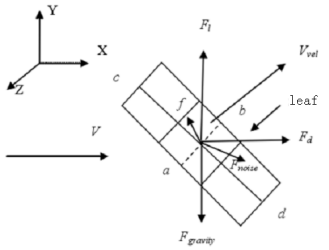

Fig-5 Force analysis of leaves in The Falling Process of Leaves

Leaves by the force F as shown in Formula (3)

$$F = F_{gravity} + F_d + F_l + F_{noise} + f \tag{3}$$

Among them, the value of $F_{gravility}$ can be calculated by the gravity formula according to the leaves' mass m, f is the air resistance, derived from the formula(4)

$$f = \lambda \cdot S \cdot V_{rel}$$
$$V_{rel} = V_{leaf} - V \tag{4}$$

Wherein, V_{leaf} represents the leaf's shaking speed ; V stands for the wind velo$_c$ity; V_{rel} is the leaves' speed relative to the wind speed; S is the area of the leaves; λ is the air resistance. That is to say, air friction has a relationship with speed leaves relative to wind and the area of the leaves.

Model of Branches Broken. The force acting on the branch can be decomposed a force $F_{branches}$ along itself direction and a vertical forces $F_{vertical}$., which value leads to the result of the branches broken.So when setting the force threshold value that the branches suffer ,we only consider the vertical force .The force analysis of acting on the branch is shown in Fig.7

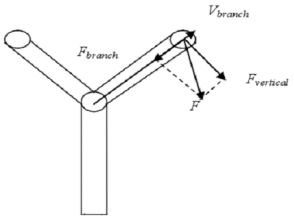

Fig -6 The force Analysis of Acting on The Branches

Statistics and Display of the Test Data. We adopted the test number in table 1 to the model of "Wind-Blowing & Tree-Swinging and Leaves-Falling & Branches-Broken".The experimental results are shown in Fig-8 and Fig-9.

Fig -7 Normal State Without Wind

Fig -8 Scenario of Leaves-Falling and Branches-Folding Under a Certain Wind

Table 1 Different Gale Can Lead to Different Affection .

Main Params	Gale #1	Gale #2	Gale #3	Gale #4
V_0	9.5m/s	11.0m/s	15.6m/s	20.0m/s
ω	3.14/320	3.14/120	3.14/180	3.14/200
β	3.14/12	3.14/4	3.14/6	0
α	4.5	5.0	6.0	5.0
λ	0.08	-0.10	0.09	-0.06

Wind velocity V=20.0m/s,wind increased gradually,more and larger branches land after fracture,then floating away on the wind direction.It takes 0.0621s.With the increasing broken branches,computation time consuming also been increased. The data analysis is shown in Table 1.

Summary

In this paper, the tree leaves in the wind, the wind blowing in a certain natural deformation under proposed a fractal technology and the physical and mechanical deformation technology combined approach. Experimental results show that the theory and methods described herein simulated "wind moving leaves off a tree branch off", you can easily and quickly get better pictures animated series to generate realistic trees and the variety and state, but in order to draw more trees form, modeling realistic trees could be improved.

Keywords: Software Evolution Process Model, Execution Model, Preparation for Resource, Knowledge Base, Resource Representation, Resource structure.

Abstract. Software evolution process model (EPM) is a knowledge-intensive process which is described in EPDL(Software Evolution Process Description Language) and modelled by semi-formal approach based on EPMM(Software Evolution Process Meta-Model). EPM's execution model (EEM) is represented by logic programming to create the knowledge base of EPM during constructing the EEM. Only its needing all kinds of resources are satisfied by system execution environment is activity in EEM implemented. The paper discussed the method and the algorithm of preparing resources is respectively presented in order to execute the EEM automatically. The converter program is realized and the correct results have presented to prove the correctness of the method.

Introduction

Resources are essential element in software evolution processes. Methods of resources' representations and managements are various with different application domain. Methodology of knowledge representation based on OWL is put forward to meet the requirement of integration management of enterprise resource [1]. Instantiation policies as a compact formalism proposes are proposed and integrated to a process modeling language to allow user-defined reusable management strategies for resource instantiation [2]. Applying multiparadigm simulation modeling in the scope of two process areas with the aim of supporting decision making and determining the optimal values of cost and schedule according to the management needs [3]. Semantic converter which converts knowledge representation in Conceptual Graphs into representation in Resource Description Framework is designed to overcome the barriers in knowledge sharing and reuse due to lack of consensus of knowledge representation formats between these two knowledge representation models [4]. Resources are encapsulated in components [5]. Software evolution processes are very sensitive to the scarcity or abundance of resources. All data, cost, time, human resources, software, hardware, and other objects supporting software evolution can be regarded as resources [6]. .Approaches above not mentioned the method of representing and preparing for the resources during executing software process.The paper proposes the method of representing and preparing for the resources in EEM. The preparation method and algorithm of resources at process level, activity level and task level are respectively proposed. According, the paper is organized as follows. Section 2 proposed resources' preparation method and algorithm. Section 3 presents the representation results of the resources in EPM's execution model using empirical data in case. Section 4 review the relative research work about EPDL and modeling approach of EPM in [6]. Finally, Section 5 draws some conclusions.

The Method and Algorithm of Preparing for Resources in EEM

Resources Needing to Preparing for. There are two kinds of resources needing to preparing in execution model of EPM. The first are input resources which are not export resources of other activities. The second is each role needed by each activity for executing, but duplicate role only needs to be instantiated once.

Method of Preparing for resources. Those supported by the environment when resources are prepared are realized by informing the environment during running the execution model. In order to realize to prepare for the resources at activity level, the EPDL file is scanned twice based on the model transformation. The four kinds of information must be reserved during scanning first which are all STRUCTURE types and all domain names and types of those domain names defined in EPM and denoted by 'TypeSet', input resources of all activities denoted by 'IRSet', export resources of all activities denoted by 'ESet', role resources of all tasks denoted by 'RSet'. The resources of set denoted by 'InitIRS' which is determined by the formula (1) are prepared.

InitIRS = IRset - ESet. (1)

Algorithm 1 . The function of algorithm is preparing for the resources for the execution model of any EPM.

Algorithm: EEPM_RES_PRERA

Input: 'pnepm' denoting the software evolution process model described by EPDL, 'InitInputRS' determined by the formula (1) and denoting resources need to prepare for, 'RoleSet' denoting role resources of all activity which need to prepare for, 'TypeSet' denoting all STRUCTURE types.

Ouput: prlgCodeS denoting resources described in execution model.

Relative Research Work about Resources in EPDL and EPMM-based Modeling Approach

The structure of resources in EPM is represented with three levels in EPDL and EPMM-based Modeling approach.

(1) The first level resources are resources at process level which describe the partial order relations among activities. These resources are control information resources of activities in EPM. If an activity has been provided with needing control information which is called precondition resources, the

activity has the execution authority. The post-condition resources will be produced after the activity has been done.

(2) Activity can be a set of tasks. Any activity is defined as an abstract data structure which includes data structures and operations on these structures. The second level resources are input resources and output resources which respectively are described by imports data structure and exports data structure. Output resources of activity are generated by activity after its execution.

(3)The third level resources are local resources demanded by the tasks in activity of EPM at task level. Roles resources described local data structures are responsible for executing task(s).

Conclusions

In this paper, representation methods of all kinds of resources in any EEM are proposed. The preparation method and algorithm of resources at process level, activity level and task level are respectively proposed. The converter program has been realized and the correct results have presented to prove the correctness of the method.

Research of Computer Forensics Based on Benford's Law

Shan Meijing

Institute of Information science and Technology, East China University of Political and Law, Shanghai, China. 201620
mjshan47@gmail.com

Keywords: Benford's Law, Computer forensics, File analysis

Abstract: In this paper we construct model in computer forensics by using Benford's Law, which is one of three famous laws in statistics in linguistics. Especially, we use Benford's Law to analyze data in file analysis and Anomaly detection. We illustrate that Benford's Law is able to supply the strategy for data analysis. The future work, Benford's Law will be the theoretical rule for intelligent compression of mass data.

Introduction

Cybercrime is one of the fastest growing and hot areas of crime. More and more criminals are exploiting the speed, convenience and anonymity that modern technologies offer in order to commit a diverse range of criminal activities.How to attempts to capture as much as possible digital evidence of the entire cybercrime investigative process, how to efficiently and effectively combat cybercrime, are very urgent issues. Computer forensics is a branch of digital forensic science pertaining to legal evidence found in computers and digital storage media. The goal of computer forensics is to examine digital media in a forensically sound manner with the aim of identifying, preserving, recovering, analyzing and presenting facts and opinions about the information.[1]

For the particularity of the electronic evidence in computer forensics, computer forensics should comply with the corresponding discipline and principle. It may involve the acquisition and analysis of digital evidence, authentication of documents, identification of sources and suspects, and so forth. From 1990's, many proposed forensic models have been studied [2-5]. Pollitt [2] identified four steps in digital forensics, as follows: acquisition, identification, evaluation, and admission of evidence, and further described admissibility of evidence. Authors in [4] use XML and OEM data model, data fusion technology, forensics knowledge base, experts inference mechanismn and mining engine to set up forensics model. Authors in [5] add time constraint and supervision procedure.

During the process of computer forensics, we need to analysis the data by knowledge of probability theory and statistics. In this paper, we construct the model in cyber forensics by Benford's law which is one of three laws in language statistics. We also use this law to analyze the file system and apply process anomaly detection.The rest content of the paper is indicated as follows: Section 2 mainly introduce the contents of Benford law and the related technologies in computer forensics. Section 3 studies the application of Benford law in computer forensics. Section 4 draw a conclusion.

Benford law

In 1881, Canadian-American astronomer and mathematician Simon Newcomb noticed that the beginning pages of the logarithmic table books were dirtier than the end pages, which indicated that the tables of logarithms were not used in a uniform way. [7]

Frank Benford was a research physicist at General Electric. In 1938, he also noticed the similar phenomenon. He found something unusual about a book of logarithmic tables. The first pages showed more wear than the last pages, indicating that numbers beginning with the digit 1 were being looked up more often than numbers beginning with 2 through 9. He published his result which about the frequency distribution of digits in many (but not all) real-life sources of data. In this distribution, the number 1 occurs as the leading digit about 30% of the time, while larger numbers occur in that position less frequently: 9 as the first digit less than 5% of the time. Benford's Law also concerns the expected distribution for digits beyond the first, which approach a uniform distribution.

Benford seized upon this idea and spent years collecting data to show that this pattern was widespread in nature. In 1938, Benford published his results, citing more than 20,000 values such as atomic weights, numbers in magazine articles, baseball statistics, and the areas of rivers.

Benford's Law(also called the First-Digit Law): A set of numbers is said to satisfy Benford's Law if the leading digit d ($d \in \{1, ..., 9\}$) occurs with probability

$$P(\mathrm{d}) = \log_{10}(\mathrm{d}+1) - \log_{10}(\mathrm{d}) = \log_{10}(\frac{d+1}{d}) = \log_{10}(1+\frac{1}{d}) \quad (1)$$

The quantity P(d) is proportional to the space between d and d + 1 on a logarithmic scale.

Nigrini appears to be the first researcher to apply Benford's law extensively to accounting numbers with the goal to detect fraud.[Nigrini 1996] More recently, papers have been published which detail practical applications of digital analysis such as descriptions of how an auditor performs tests on sets of accounting numbers, how an auditor uses digital analysis computer programs, and case studies for training students. However, Benford law does not suit for all the data, such as Lotto number, telephone number etc.

Table1 Based on the frequency of the digital distribution of Benford's law

	First digit	Second digit	Third digit	Fourth digit
0		.11968	.10178	.10018
1	.30103	.11389	.10138	.10014
2	.17609	.10882	.10097	.10010
3	.12494	.10433	.10057	.10006
4	.09691	.10031	.10081	.10002
5	.07918	.09668	.09979	.09998
6	.06695	.09337	.09940	.09994
7	.05799	.09035	.09902	.09990
8	.05119	.08757	.09864	.09986
9	.04576	.08500	.09827	.09982

Application of Benford law in Computer Forensics

Many evidences are potential in computer crime. The files the users set up may include important information
of crime activity. In many cases, suspects hide or modify the files, such as hide the important files in some partition or in some seems irrelevant file folders. Computer forensics should consider the properties of files. The tracked operations include time of files or file folders' creation, last modification, last access, movement and deletion, the owner, the access privilege.

When delete a file, the intuitive result is that the file name dispears from the directory list, and the file name and inode number of directory entries are marked unused. Some file systems, such as Microsoft FAT16 and FAT32, will hide the file name by a special configuration, then the file is marked for deletion. The traditional Berkeley Fast File System (FFS) will be disconnected directory entries, all file attributes and file data connections between data blocks. Extended FFS usually be found between Solaris and BSD system. Here we only discuss the cases which can access local file system, not about remote file system.

Actually, the files in computer system are not only the ones user set up but also the ones of operating system, which includes backup files, log files, configuration files, swap files, system files, hidden files, and temporary files etc. The sizes of these files obey the probabilistic distribution described in Benford Law. We got all the files in system disc by some instructions, and find the size of these files obey Benford law, shown in Table 2. In this table, "FSD" which starts wih digit 1~9 means the size of file, "Total" means the number of files, "Actual" means the proportion of the file, "Benford" means the proportion of the file calculated by Benford law.

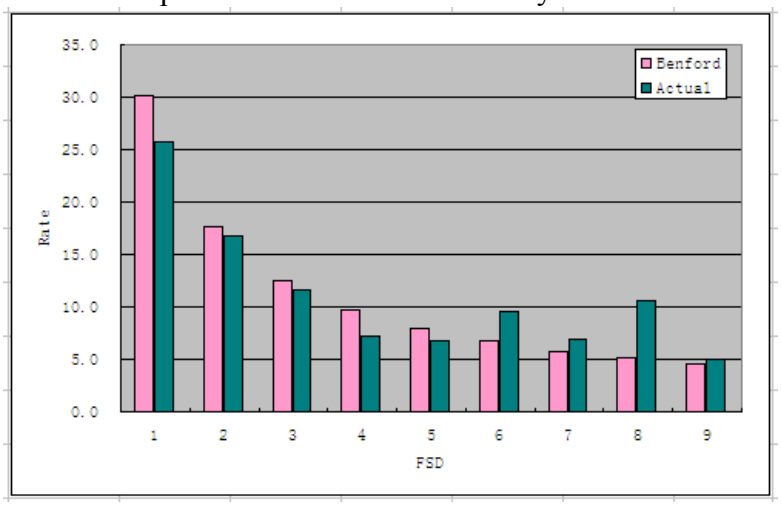
Table2 The size of file in system disk

FSD	Total	Actual(%)	Benford(%)
1	4451	25.7	30.1
2	2900	16.7	17.6
3	2003	11.6	12.5
4	1243	7.2	9.7
5	1181	6.8	7.9
6	1651	9.5	6.7
7	1207	7.0	5.8
8	1825	10.5	5.1
9	870	5.0	4.6
0	19		

Compare the data in "Actual" and "Benford" column in Table2, we find they are similar. We use 2 for example. There are 2900 files which start with 2 in system disk, accounting for 16.7% of the total file. The calculating result is 17.6%. We compare the results and give the compared analysis chart as Table3.

By a large mount of experiments, we find the size of file in computer has the similar law. It supplies theoretical judgment strategy for anomaly detection of files in computer forensics.

Table3 Compare with the size of fiels in system disc and Benford law



Conclusion

The research work of this paper is very rough. The further research work will use Benford law and formal method to study the digital evidences and models in computer forensics. We also plan to use knowledge of probability statistics to reduce the size of mass data with a TB level, for improving the analyzable of digital evdiences.

Keywords: popularity data; Zipf distribution; prediction

Abstract. In this paper we propose to use Zipf-like distribution to predict popularity data in storage systems. It can estimate prediction parameters according to the present statistics of I/O access. We classify the popularity data from every trace, and analyze the prediction rate through the classified popularity data's characteristic. We synthesize the analysis results in different prediction time granularity and prediction popularity data queue. Finally, we use block I/O traces to discuss the effectiveness of prediction method. The discussion and analysis results indicate that this prediction method can predict the popularity data efficiently.

Introduction

The access patterns of many applications reveals certain characteristics: high workloads, large number of users, massive data and many storage nodes. But the most notable characteristic of this access pattern is: 80% IO requests only access 20% data, which is known as "Pareto principle" [1]. These characteristics lead to the emergence of popularity data in storage system. As a result, how to predict these popularity data is a critical research focus in optimization of storage systems.

In order to use popularity data, some researchers have given a solution on the popularity data prediction [2-5]. But we develop a new Prediction Popularity Data Model (PPDM) based on Zipf-like distribution [6]. We first estimate parameters according to the present statistics of I/O access: α parameter, time granularity, and auxiliary parameters such as access frequency's growth rate, popularity data queue and the least accuracy rate etc. Then we use block I/O traces to discuss the effectiveness of PPDM. We classify the popularity data, and analyze the prediction rate through the classified popularity data's characteristic. Finally, we synthesize the analysis results in different time granularity and prediction popularity data queue. The discussion and analysis result above indicate that PPDM can predict the popularity data efficiently.

Prediction Popularity Data Model

Zipf observed long time ago that the distribution of word frequencies in English, the rank-r word has the probability P_r, and M denotes all data in the storage system, so the probability distribution is

$$P_r = \frac{C}{r^{\alpha}}, \sum_{r=1}^{M} P_r = 1 \Rightarrow C = \left[\sum_{r=1}^{M} \frac{1}{r^{\alpha}} \right]^{-1} \tag{1}$$

In one application environment, the value of α in Zipf's Law is a constant, and according to Eq. 1, we have C(kT)=C(T). At the time T or kT, if a data in the popularity data queue, f_r denotes the access frequencies , according to Zipf-like distribution in Eq. 1, the access probability of the D_r and Dr′:

$$P_r(T) = \frac{C}{r^{\alpha}} = \frac{f_r(T)}{F(T)}, P_{r'}(kT) = \frac{C}{r'^{\alpha}} = \frac{f_{r'}(kT)}{F(kT)} \Rightarrow \frac{f_r(T)}{F(T)} r^{\alpha} = \frac{f_{r'}(kT)}{F(kT)} r'^{\alpha} \tag{2}$$

In order to simplify the computation, if M remain unchanged from time 0 to kT and assume that F (the total number of access frequencies) is a linear function which only decided by time (this condition conforms to the most of access pattern of the practical application environment). So we have:

$$\frac{F(kT)}{F(T)} = k \tag{3}$$

According to Eq. 2 and Eq. 3, we have:

$$\frac{r'^{\alpha}}{r^{\alpha}} = \frac{f_r(T)}{F(T)} \cdot \frac{F(kT)}{f_{r'}(kT)} = k\frac{f_r(T)}{f_{r'}(kT)} \tag{4}$$

At the time t=kT, we just evaluate the ratio of $f_r(T)/f_{r'}(kT)$. So, considering the extreme scenario, the access frequency of D_r doesn't increase from the time T to kT ($f_r(T) = f_{r'}(kT)$). Eq. 4 is revised to:

$$\frac{r'^{\alpha}}{r^{\alpha}} = k \Rightarrow r' = k^{\frac{1}{\alpha}} \cdot r \Rightarrow r' \le Q_h \Rightarrow r \le Q_h \cdot k^{-\frac{1}{\alpha}} \tag{5}$$

If the k or T too large, the predicted is always popularity. So, we introduce a new concept: "Growth-rate of access frequency". If $G_r(t_1,t_2)$ denote as Growth-rate of access frequency from t_1 to t_2, it is calculated by:

$$G_r(t_1,t_2) = \frac{f_r(t_2) - f_r(t_1)}{t_2 - t_1} \Rightarrow G_r(t) = \lim_{\Delta T \to 0} \frac{f_r(t) - f_r(t-\Delta T)}{\Delta T} \Rightarrow \Delta f_r(t) = \Delta T \cdot G_r(t) \tag{6}$$

For a non popularity data D_r at time t=T, to become popularity at time t=kT, it must satisfy:

$$f_r(T) + (k-1)\cdot G_r(T) \ge f_{Q_h \cdot k^{-\frac{1}{\alpha}}}(T) + (k-1)\cdot G_{Q_h \cdot k^{-\frac{1}{\alpha}}}(T) \tag{7}$$

At the time t=kT, with the $G_r(t_1,t_2)$ during ΔT to calculate the access frequency of $D_{r'}$, we have:

$$f_{r'}(kT) = f_r(T) + (k-1)\cdot G_r(T) \tag{8}$$

Estimating parameters of the PPDM

Estimating α parameter. In Zipf-like distribution, we first have: C is equal to the most frequently occurring data that appears in the storage system with the probability P_1, if r=1, then P_1=C.

In order to acquire many methods to estimate the value of α, we convert Eq. 2 and have(r<j):

$$\frac{P_r}{P_j} = \frac{C/r^{\alpha}}{C/j^{\alpha}} = (\frac{j}{r})^{\alpha} \Rightarrow \alpha = \frac{\lg(P_r/P_j)}{\lg(j/r)} \tag{9}$$

According to Eq. 9, we compute many values of α and acquire arithmetic mean value and geometric mean value. At the time t=T, we choose the access frequency N is 100 thousand. If we choose two different r and j from (1, 2⋯10), which can compute 45 different α values. The simplest method to judge whether the value of α is reasonable or not: if q_r=P_r and C=P_1, transferring Eq. 1, we have:

$$q_r = \frac{C}{r^{\alpha}} = \frac{P_1}{r^{\alpha}} \tag{10}$$

Table 1 The fit ratios of the most reasonable α in Hm_0.

α	p_1/q_1	p_2/q_2	p_3/q_3	p_4/q_4	p_5/q_5	p_6/q_6	p_7/q_7	p_8/q_8	p_9/q_9	p_{10}/q_{10}
1.042963395 (arithmetic mean)	1	1.84	1.08	1.36	1.52	1.23	1.09	1.24	1.25	1.34
0.889309111 (geometric mean)	1	1.65	0.92	1.1	1.19	0.85	0.81	0.9	0.89	0.94
0.329392	1	1.12	0.5	0.51	0.48	0.31	0.27	0.28	0.26	0.26
0.94	1	1.71	0.97	1.18	1.29	0.94	0.89	1	1	1.06

On the whole if q_r is close to p_r, α is reasonable, otherwise α is unreasonable. We utilize (Fit ratio) P_r / q_r to judge whether q_r (Fit frequency) is close to p_r. The more P_r / q_r is close to 1, the more q_r is close to p_r. For example: (Hm_0). When r=9 and j=10, we compute the value of α is 0.329392, the fit ratios of this α are shown as Table 1. Most of the fit ratio is close to 0 (much less than 1), so this α value is unreasonable. According to our calculation, the most reasonable value of α is 0.94. The fit ratio of the most reasonable α in Financial_2, Ts_0 and Proj_3 are 0.62, 1.34 and 0.68.

Estimating k parameter. The most important evaluation criterion is Popularity Prediction Accuracy (PPA): the ratio of true positive predicted popularity data to the popularity data queue:

$$PPA(t) = \frac{P(t)}{Q_p} \tag{11}$$

In Eq. 5, we have $Q_p \cdot k^{-\frac{1}{\alpha}}$, this is the boundary value of the data which is still in the new popularity data queue, if only the data rank smaller than or equal to this value, it is still popularity data. So we have:

$$PPA(kT) \geq \frac{Q_p \cdot k^{-\frac{1}{\alpha}}}{Q_p} = k^{-\frac{1}{\alpha}} \tag{12}$$

In Eq. 12, if $PPA(kT) = k^{-\frac{1}{\alpha}}$, defined as Minimum Popularity Prediction Accuracy (PPA_m). We can make sure that if PPA_m value is high, then the prediction time is short, and PPDM can not reflect the efficiency; if PPA_m value is low, then the prediction time is long, and the results of the prediction model might be not accurate. So, we first choose 5 values about PPA_m: 10%, 20%, 30%, 40% and 50%, and then we compute 5 values of k. We define $k_1T=T_1$, $k_2T=T_2$, $k_3T=T_3$, $k_4T=T_4$ and $k_5T=T_5$, meanwhile, $T_1>T_2>T_3>T_4>T_5>T$. In four traces, some of them are small data sets, some are big data sets. Based on PPDM, the popularity data queue is 30, 40, 50, 60, 70, 80, 90, 100 and 200.

Experiments and analysis

I/O workloads. The workloads that drive our experiments consist of two major parts: SPC I/O traces and data center server traces. Four different traces are used, Financial_2 (read-dominant) is typical of small and short-period data centers. Ts_0 (write-dominant), Proj_3 (read-dominant) and Hm_0 (almost the same read and write amount) which are typical of big and long-period data centers. The write ratio of these traces is about 18%, 82%, 5% and 65%, respectively.

Prediction rate results. The results of prediction rate are shown in Fig. 1-2. In these figures, the prediction rate at the time T_5 is higher than the results at other prediction time, the reason is we use unchanged parameters at the time T to predict popularity data rank from k_1T to k_5T, but in real application, when current time is k_3T, our PPDM prediction is dynamical, and the parameters used in model would adjust according I/O access condition, we would use related parameters at the time k3T to predict k_2T or k_1T, thus the accuracy of popularity data prediction model would be higher.

Results analysis. Periodical popularity refers to a block of data accessed frequently in a time period. Ts_0 has periodical popularity characteristics. The trace data ranked top in the growth rate of access frequency during ΔT, but fall behind during time T. Therefore, the time from 0.8T to T will be predicted as a new popularity data in the next period. But, the actual access is on the contrary, as the growth rate in T to KT decreased, which lead to a drop in the rank, so some of prediction in KT period is relatively low.

Temporary popularity refers to the data that transfer from seldom visited to the focus of data access, and when they become popularity data, other data fall behind in the rank. Proj_3 has periodical popularity characteristics. The access frequency of these data stay unchanged from 0.9T (or 0.8T), and become leading in the access frequency rank. Therefore, these data will be predicted as the new popularity in the next moment. However, the actual access situation is on the contrary: the popularity

access frequency stays unchanged in KT, while other data's access frequency increase, which leads to the actual rank fall behind compared to moment T, so part of the prediction in KT is not so accurate.

Hm_0 is trace that contain both temporary and periodical characteristic. So the prediction rate of these traces can be affected by both effects. It is not certain whether these traces of two traits stand for a low prediction rate, which was mainly determined by the quantity of these data.

The prediction of popularity rate Financial_2 is very stable now, and the rate is fairly high.

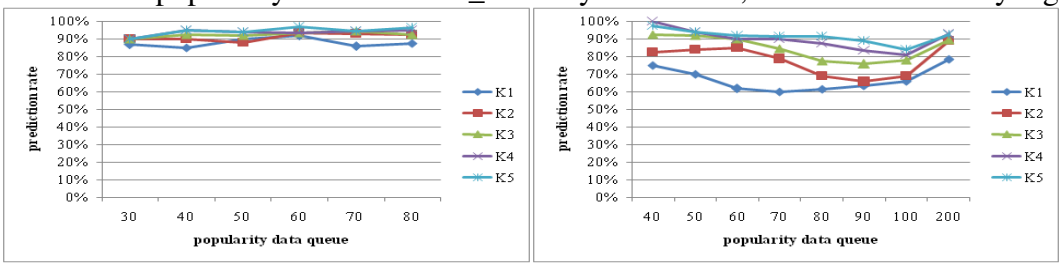

Figure 1. Prediction rate of Financial_2 and Ts_0 (left figure is Financial_2 and right figure is Ts_0).

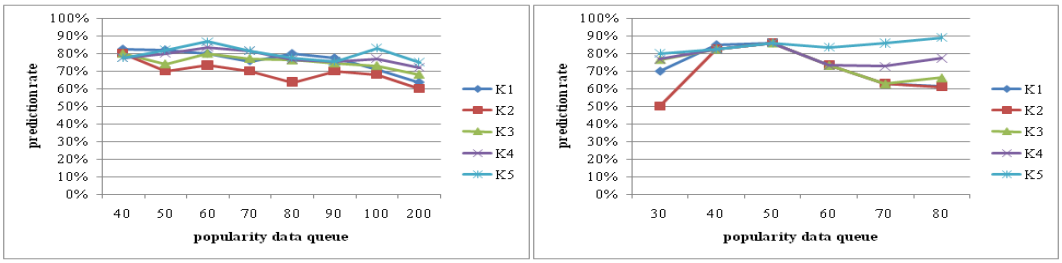

Figure 2. Prediction rate of Hm_0 and Proj_3 (left figure is Hm_0 and right figure is Proj_3).

Summary

In this paper, we propose a Prediction Popularity Data Model (PPDM) based on Zipf distribution. We combine the different characters of every trace, use different popularity data queue and prediction time to demonstrate the efficiency. We can draw the conclusion that short prediction time has high prediction rate (over 90%). From the analysis of periodical and temporary popularity, we get the conclusion that different popularity data queue have no regularity on the prediction results of PPDM.

Abstract: This paper employs the Minimum Arborescence model to handle the spatial structure analysis of a mathematical formula, and transforms the directed graph to a trigeminal tree. Also, we utilizes the preorder traversal algorithm of the Ternary-Tree to generate MathML, and display the MathML with Web browser. At last, the experimental results illustrates the recognition rates of online handwritten mathematical formula in various cases.

Introduction

Recently, the recognition based on image processing has been widely applied in many fields such as document recognition in bank, license plate recognition on road, pupil detection in medical treatment, and etc. The recognition of online handwritten character is an interdisciplinary problem based on the theories of digital image processing, statistical decision theory, machine learnign, pattern recognition, etc. The recognition of online handwritten character is now becoming more and more practical, especially in English charters, which has begun to implement unlimited whole-sentence recognition. However, The recognition of online handwritten mathematical formula is much more difficult than that in English charters. Firstly, collecting handwriting is more complicated. Secondly, there is not the specific symbol of mathematical formula in the computer character set. Thirdly, the nest in the formula makes the problem more difficult. Since neural network algorithm[1] and support vector machine(SVM) algorithm [2]have been applied successfully, the recognition rate of handwritten characters reaches 95%, which settled the character recognition of online handwritten mathematical formula. Meanwhile, due to the instantaneity, high efficiency, "what to write is what you get" and other features, the recognition of online handwritten mathematical formula still attracts attentions of researchers.

For the structure analyze of mathematical formula, the common methods are grammar LL(1), minimum spanning tree[3,4,5] and ternary tree. Grammar LL(1) utilizing stack architecture conducts derivation from the start symbol of grammer by the repeated use of production until incoming symbol comes out. Grammer LL(1) requires the complete accuracy of the formula, because it can not judge a wrong one. Minimum spanning tree resorts to the tree with minimum weight among all spanning trees of undirected connected gragh. It has to solve the circle-breaking problem of undirected gragh first, but not emphosize the complicated mathematical structural analysis. Ternary tree sets up a ternary tree based on the priority of operator, but more efforts should be made in the generation of ternary tree. Minimum arborescence was first presented by Zhu Yongjin and Tian Feng in 1965 to solve channel design problem. But, the issue is that in channel design, water should be led to several points, and the bifurcation of channel must be at the given point, and the total channel route should be the shortest. The difference between minimum arborescence and minimum spanning tree is that water always flows in a direction. Recently, many researchers focused on the study and application of minimum arborescence. Zhai Xiaoyan[6] proposed the application of minimum arborescence in network. Sun Lingyu[7] presented the algorithm of empowerment minimum arborescence, which

used the model of minimum arborescence to solve the structural analysis of online handwritten mathematical formula and generate ternary tree.

The Structural Analysis of Mathematical Formula

The nest in mathematical formula makes the problem more complicated. Compared to the structural analysis of character recognition, there are various patterns in mathematical formula such as front-back relation (like $a+b$), up-down relation ($\frac{a}{b}$), super-subscript relation (like ∂_2^3), internal relation (like $\sqrt{2}$) and etc. There are two popular methods in studying character relation of mathematical formula: base line and "Jing" font. Base line is to solve the type-setting problem of printing characters, but not good at dealing with the nested and complex formula. "Jing" font judges the relation of two characters according to the spacial position information of every mathematical character in the formula such as up-down, left-right, up-right, up-down relation and etc. However, "Jing" font may lead to misjudgment due to some spacial position relations between characters.

Based on the structural analysis of mathematical formula, some rules come up as follows:

(1) Writing mathematical formula is in the left-right order. A character and its following characters can form a sector structure, e.g., ∂_2^3+b, three characters form a sector structure surrounding "∂" (character "∂" relates to the following subscript "2", superscript "3" and "+");

(2) Some characters form the up-down relation, like $\frac{a}{b}$;

(3) Special character radical sign and its internal character form internal relation.

The above analysis shows that in a mathematical formula, at most four characters can have effective relation with one character, among which at most three characters are its in-coming characters and one character is its out-going character. It is same with the link between nodes of minimum arborescence. Therefore, it is feasible to solve the structural analysis problem of mathematical formula by establishing a minimum arborescence model.

Establishing a Minimum Arborescence Model

Set the relations of characters in mathematical formula as follows:

(1) For number, letter and so on, the sector structure is in priority in spacial position relation, that is, super-subscript and right relation.

(2) For special characters like "—", "$\sum$" ,etc., the up-down and right relation are in priority in spacial position relation like $\frac{a+b}{c+d}+e$. Character "—" has three relevant characters "a", "c" and "+".

(3) For special character like radical sign "$\sqrt{\ }$", the internal and right relation is in priority in spacial position relation. For example, in $\sqrt[c]{a+b}+d$ the relevant characters of radical sign are "c", "a" and "+".

Process of generating minimum arborescence:

(1) Sort the characters in the order from left to right regardless their spacial relation.

(2) Retrieve special character in the order from left to right, and look up its relevant characters by relation rules. If the selected relevant character has been related to other special characters, give it up. Otherwise, tab it.

(3) Conducting relational analysis among the remaining characters from left to right, and seek out its relevant character successively. If the selected relevant character has been related to other characters, give it up. Otherwise, tab it.

The merit of this method is that one node will not have multiple pre-nodes in the generated minimum arborescence, meanwhile, mis-relation might exsit in some handwritten messy mathematical formulas. Fortunately, the effect of mis-relation can be deduced due to the recognition is online

operation, which provides real-time display so that the user can immediately revise the written character.

The structural analysis of the formula shown in **Fig. 1** with the above method and the generation of minimum arborescence are shown as follws:

$$\frac{a_x^y + b_y^x}{(\sqrt{c-d})^f} - \sum_{i=1}^{n}(i^k + p)$$

Fig. 1 Mathematical Formula

(1) Sort the characters in the order from left to right as follows:

$$\underset{1}{-},\underset{2}{(},\underset{3}{a},\underset{4}{\sqrt{\ }},\underset{5}{x},\underset{6}{y},\underset{7}{c},\underset{8}{-},\underset{9}{+},\underset{10}{d},\underset{11}{b},\underset{12}{)},\underset{13}{y},\underset{14}{x},\underset{15}{f},\underset{16}{-},$$

$$\underset{17}{\sum},\underset{18}{i},\underset{19}{=},\underset{20}{1},\underset{21}{n},\underset{22}{(},\underset{23}{i},\underset{24}{k},\underset{25}{+},\underset{26}{p},\underset{27}{)}$$

(2) Look up the relevant characters of special character, according to the node relation format of digraph as follows:

Node 1：<1,3>，<1,2>，<1,16>；

Node 4：<4,7>，<4,12>；

Node 8：<8,10>；

Node 16：<16,17>；

Node 17：<17,18>，<17,21>，<17,22>；

（3）Look up the relevant characters of common character from left to right:

Node 2：<2,4>；Node 3：<3,5>，<3,6>，<3,9>；

Node 7：<7,8>；Node 9：<9,11>；

Node 11：<11,13>，<11,14>；Node12：<12,15>；

Node 18：<18,19>；Node 19：<19,20>；

Node 22：<22,23>；Node 23：<23,24>，<23,25>；

Node 25：<25,26>；Node 26：<26,27>；

The generated minimum arborescence is illustrated as **Fig. 2.**

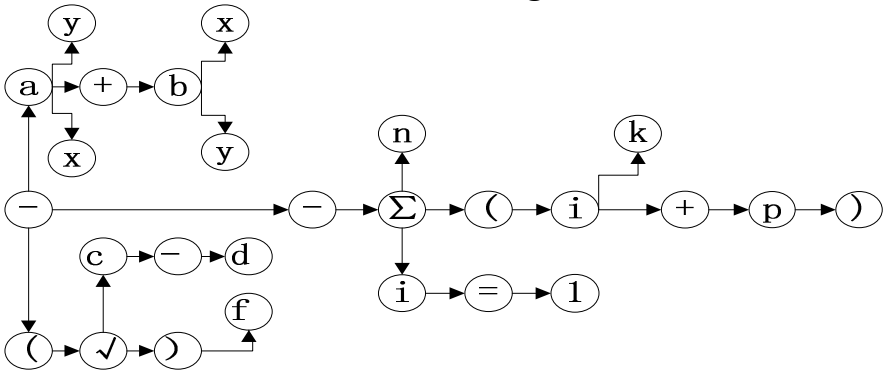

Fig. 2 Minimum Arborescence

Generating Ternary Tree

Minimum arborescence model can analyze the structure of mathematical formula accurately and manage the relation between two nodes, but can not handle the relations between child nodes. By switching the minimum arborescence model into ternary tree model, the position of nodes on each layer can be located. The minimum arborescence in **Fig. 2** switches into ternary tree model shown as **Fig. 3.**

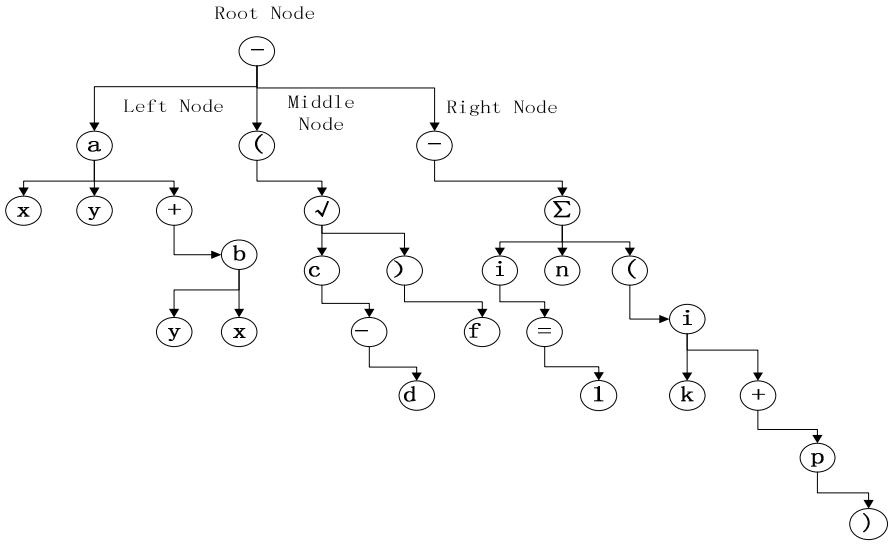

Fig. 3 Ternary Tree

Compared the ternary tree and minimum arborescence, we can find that the left node of root node "—" is "a", middle node is "(", right node is "—".

Take N as the root node, and L, M, R as the left subtree, middle subtree and right subtree of N respectively. There are four ways[8] in the depth-first traversal of a ternary tree: NLMR, LNMR, LMNR and LMRN order.

Generating MathML

W3C Mathematics Workgroup first put forward MathML[9,10]. MathML describes the structure and content of mathematical expression with XML, whose goal is to enable Web to serve, receive and process mathematical formula. MathML offers two marks describing mathematical formula: Content mark and Presentation mark. The former focuses on the content of expression, while the latter pays more attention to its display mode. The popular web browsers like Mozilla, Firefox and Netscape Navigator all support MathML directly. The Internet Explorer of Microsoft can also recognize MathML after installing the plug-in MathPLayer.

The structure of MathML is in the same NLMR order with ternary tree. From the structural analysis of 100 handwritten mathematical formula (including number, English capital and small letter, operator and so on) written by several experimenters, it turns out 88 correct structures and 12 wrong structures. The main elements causing mistakes are that two characters in joined-up writing are taken to be one character, and the combination recognition of structural body (like log, lim). Therefore, the method remains to be further improved, for instance, context semantic analysis will be the future directon of study.

Experiment

The recognition results of online handwritten mathematical formula shown in **Table 1** are conducted by the proposed method.

Table 1 Experiment Results

Type	Time	Correct	Accuracy(%)	Second Correction	Uncorrectable	Accuracy after Correction (%)
Up-Down Structure	200	176	88	24	0	100
Sector Structure	200	182	91	28	0	100
Radical Sign	200	170	85	26	4	98
Integral	200	177	88.5	10	13	93.5
Triangular Symbol	200	186	93	8	6	97
Complex Structure	200	164	82	21	15	92.5

The table shows that the recognition rate after the second correction reaches 92.5%. There are two main elements: two characters in joined-up writing are taken to be one character, and the combination recognition of structural body (like log, lim). Therefore, the method remains to be further improved. For instance, intelligent semantic analysis will be the future directon of study.

Conclusion

The paper offers a method to switch online handwritten mathematical formula into MathML, and first time put forward the idea that describing the spacial structure between characters by using minimum arborescence. Compared to the traditional base line and "Jing" font, it improves the accuracy of recognition in the structural analysis of nonstandard mathematical formula. As well, the proposed paper suggests that describing the spacial structure between characters with digraph model possesses portability, which can also be applied in the formula recognition of other subjects.

Keywords: OFDM; greedy algorithm; adaptive; bit Allocation.

Abstract. For the greedy algorithm required a large number of iterations, this paper proposed one adaptive bit allocation algorithm based on Hughes-Hartogs algorithm which was improved greedy algorithm .Under the constraint of bit error rate and data transmission rate, the algorithm first used the Chow algorithm to allocate some of the bits, and then used the greedy algorithm to allocate the remaining bits. When minimize the total power by this algorithm, the iterations of this algorithm were significantly less than the greedy algorithm. By computer simulation, the results showed that performance of this algorithm was very close to the greedy algorithm, and the number of this algorithm's iterations was 7.4%~34% of the greedy algorithm.

Introduction

In the Orthogonal Frequency Division Multiplexing (OFDM) system, each subchannel will also influence the channel fading, so each subchannel will has different transmission ability. Assuming that each subchannel using the same modulation and the system can work normally, the system parameters will be designed by the subchannel which has the worst transmission capacity, but the system resources will not be fully utilized. Utilize the subchannel which has good relative characteristics has a great significance, This needs adaptive modulation.

There are many kinds of adaptive algorithm, for example, Hughes-Hartogs algorithm[1], Chow algorithm[2]. Reference [3] proposed an improved greedy algorithm, but the improved part still needs a few iterative computation. Reference [4] points out severely frequency selective fading channel and in low SNR, you cannot use the Chow algorithm. Aiming at this defect, it proposed an improved algorithm to make up this defect. Reference [5] did a comparative analysis of the adaptive bit allocation algorithm, the optimal power allocation algorithm and suboptimal power allocation algorithm. It reached a conclusion that adaptive bit allocation technology can optimize capacity and the bit error rate of the system, and it's an effective algorithm. Reference [6] proposed an improved water filling algorithm, which is a suboptimal bit allocation algorithm, but this algorithm programming is more complex.

This paper aiming at the deficiencies that using the greedy algorithm to adaptively allocate bits needs many times of iteration[7]. Before entering the greedy algorithm, according to the characteristic of the channel, use the Chow algorithm to allocate some bits in advance, the remaining bits use the greedy algorithm to allocate.

Problem Model

Bit allocation has two standards: margin maximization criterion and rate maximization criterion[8]. This paper adopts margin maximization criterion, its optimal model is as follows:

Assuming that the number of subcarrier is N, the bits allocate in subcarrier are b_n, the power allocate in subcarrier is p_n. In the actual communication system, b_n is usually an integer. We need solve the problem that in a certain data rate and bit error rate, to make the transmission power of the OFDM system achieve the minimum. i.e.

$$\begin{cases} \min mize \sum_{n=1}^{N} p_n \\ s.t. \sum_{n=1}^{N} b_n = R \end{cases}, N = 1, 2, \cdots, N. b_n \in Z, b_n \geq 0 \tag{1}$$

Improved Greedy Algorithm

The Theoretical Basis of The Improved Greedy Algorithm. Assuming that there is Gauss noise in the channel, bandwidth is W, and its transmission function is $H(f)$. (power spectral density (PSD) is $N(f)$. At the same time, when the SNR $|H(f)|^2 / N(f)$ is approximately constant in the subchannel bandwidth, the channel bandwidth W can divided into $N = W / \Delta f$ subchannels, Δf is the subchannel bandwidth. And the signal's transmission power should meet

$$\int P(f) df \leq P_{av} \tag{2}$$

P_{av} is the average power.

Finally, through the transformation can obtained:

$$P(f) = \begin{cases} K - N(f) / |H(f)|^2, f \in W \\ 0, f \notin W \end{cases} \tag{3}$$

The physical meaning of the above formula: when the SNR $|H(f)|^2 / N(f)$ is low, the corresponding channel power is also low, and when the SNR is high, the channel power is also high.

Analysis of Greedy Algorithm. In this paper, the greedy algorithm is compared with the improved algorithm. Its steps are as follows:

(1) Let $b_n = 0, p_n = 0, n = 1, 2 \cdots, N.$

(2) Calculate the additional power Δp_n, when each sub carrier increase a bit.

(3) Select $n^* = \arg\min_{1 \leq n \leq N} \Delta p_n$, if $\sum_{n=1}^{N} b_n > R$,end. If not, let $b_{n^*} = b_{n^*} + 1, p_{n^*} = p_{n^*} + \Delta p_{n^*}$, return to (2).

$\{b_n, n = 1, 2, \cdots, N\}$ is number of bits for each subcarrier, $\{p_n, n = 1, 2, \cdots, N\}$ is transmission power for each subcarrier. Finally, the minimum transmission power is $P = \sum_{n=1}^{N} p_n$. Using the greedy algorithm, we can obtain the optimal solution. But when the greedy algorithm allocates a bit, it always needs one iteration. So with the increase of transmission rate, number of iterations needed by the algorithm will increase.

Analysis of Improved Greedy Algorithm. The basic idea of the improved greedy algorithm: before entering the greedy algorithm, according to the characteristic of the channel, use the Chow algorithm to allocate some bits in advance, we need calculate p_n (the transmission power of each subcarrier), b_n (the bits of each subcarrier). At the same time, we also need calculate R_1 (the total number of bits) and the energy that sends these bits required. The remaining bits R-R_1 use the greedy algorithm to allocate each subcarrier.

The Chow algorithm used as allocated in advance. Its steps are as follows:

(1) Estimation SNR of each subchannel;

(2) According to the formula:

$$\hat{b}_n = \log_2(1 + SNR(n) / (GAP + \gamma)) \tag{4}$$

To estimate number of bits for the each subcarrier, γ is the performance threshold;

(3) $\hat{b}_n$ round to b_n;

(4) Limit the value of b_n is $0, 1, 2, 4, 6, 8$ (related to the modulation sequence);

(5) Based on the formula, we can calculate the energy of each subcarrier with b_n bits.

$$p_n = (2^{b_n} - 1) / SNR(n) / GAP \tag{5}$$

GAP is an effective coordinating parameters.

The improved greedy algorithm's steps are as follows:

(1) Initialized by the Chow algorithm, we can get the initial b_n, p_n.

(2) Let b_n, p_n of the greedy algorithm is equal to the b_n, p_n which was obtained in (1).

(3) Calculate the additional power Δp_n, when each sub carrier increase a bit.

(4) Select $n^* = \arg\min_{1 \le n \le N} \Delta p_n$, if $\sum_{n=1}^{N} b_n > R$,end. If not, let $b_{n^*} = b_{n^*} + 1, p_{n^*} = p_{n^*} + \Delta p_{n^*}$, return to (3).

Simulation Results and Analysis

The simulation parameters: number of the subcarriers are $N = 64$, wireless channel is used for 3 path Rayleigh fading channel, channel gain vector are $\left[1 \;\; 1/e \;\; 1/e^2\right]$, the bit error rate is $BER = 10^{-4}$, and assuming that the channel state is not invariant in a OFDM symbol period. MQAM modulation can be used for BPSK, QPSK, 4QAM, 16QAM, 64QAM and 256QAM. This paper through two indicators which are iterative and transmission energy, to compare the greedy algorithm and the improved algorithm, thus get the performance comparison between two algorithms.

Figure 1 shows that this algorithm meets the expected effect. When the channel condition is bad, allocate a few bits; when the channel condition is good, allocate many bits. That is this improved algorithm is effective. Compared with Figure 2, each subcarrier's bits and transmission power between two algorithms are almost same, so can get the improved greedy algorithm and the greedy algorithm are very close in performance.

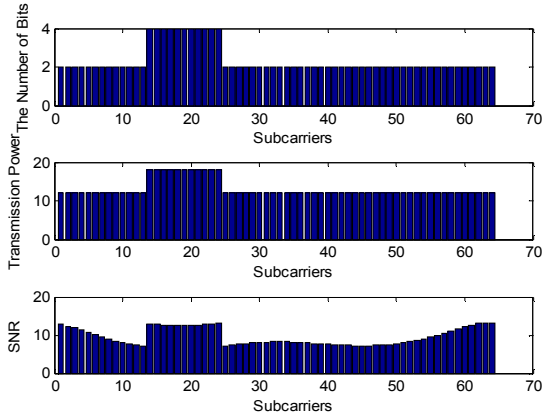

Figure 1. $R = 150$, the allocation results of the improved greedy algorithm.

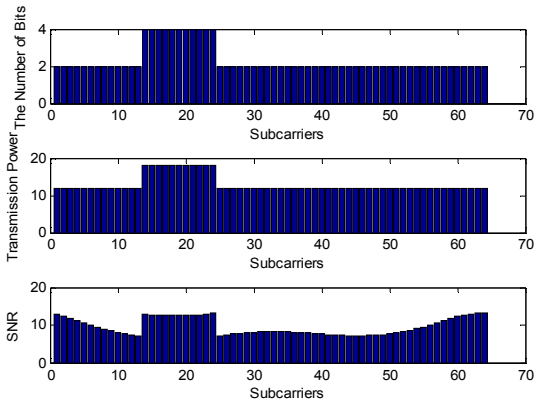

Figure 2. $R = 150$, the allocation results of the greedy algorithm.

Figure 3 is an iterative times comparison between the greedy algorithm and the improved greedy algorithm. It shows that the curves of two algorithm are almost coincide. With the increase of transmission rate, the number of bits which required modulation are also increase and the iterative times of two algorithms will also increase. But the iterative times of the greedy algorithm increase more than the iterative times of the improved greedy algorithm. When the transmission rate is 150, the iterative times of the improved greedy algorithm are the iterative times of the greedy algorithm 7.4%; When the transmission rate is 250, the iterative times of the improved greedy algorithm are the iterative times of the greedy algorithm 24.4%; When the transmission rate is 350, the iterative times of the improved greedy algorithm are the iterative times of the greedy algorithm 31.7%. Therefore the improved greedy algorithm reduces the number of iterations is obvious. Figure 4 is at different transmission rates, a transmission power comparison between the greedy algorithm and the improved greedy algorithm. When the number of iterations obviously reduced, the performance of the improved

greedy algorithm is very close to the greedy algorithm. At the same time, the realization of the improved greedy algorithm is also relatively simple.

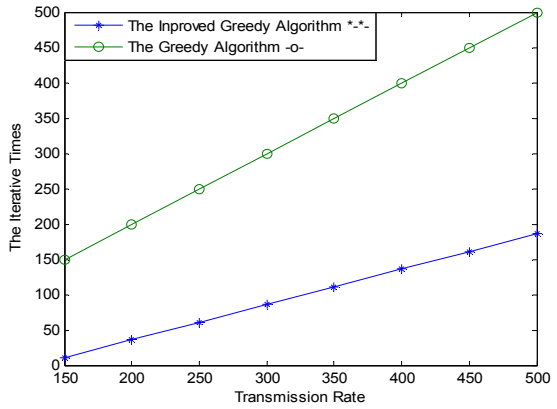

Figure 3. An iterative times comparison between two algorithms

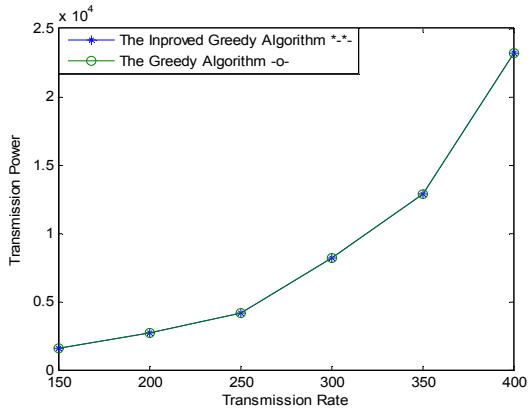

Figure 4. A transmission power comparison between two algorithms

Summary

Aiming at the greedy algorithm using adaptive bit allocation needs many times iteration in OFDM system, we propose an improved algorithm, which improving the initialization of the greedy algorithm and obviously reducing the iterative times of computation required. The simulation results show that, the iterative times of the improved greedy algorithm are obviously less than the greedy algorithm and its realization is simple, but the performance of improved greedy algorithm is very close to the greedy algorithm.

Keywords: stepped cooling control, cooling capacity, flatness accuracy, temperature field, optimal algorithm

Abstract. A 1450mm cold rolling mill roll stepped cooling control technology has been studied. The basic principle of stepped cooling control has been analyzed. The important role of stepped cooling control in the control of thermal crown has been elaborated. In order to analyze impact of stepped cooling on the sectional shape of the strip, the roll under the influence of the cooling water temperature field has been established. The model of optimal cooling capacity in each segment has been established. The model has been successfully applied to a 1450mm cold rolling mill roll, and a good effect has been achieved.

Introduction

The traditional roll control is essentially to establish sub-cooling and cooling control model PID control cooling flow through the study of the impact on the shape and the corresponding heat transfer coefficient[1]. The traditional roll stage cooling PID control method has been unable to meet the high quality requirements of flatness control. In order to increase flatness accuracy, the gradient projection method has been adopted and the ploy of stepped cooling control has been optimized.

Definition of stepped cooling control

When the complex defects can not be eliminated by tilting, bending and shifting, the stepped cooling control can only be adopted to control flatness[2]. The measurement segment of stepped cooling is in correspondence with flatness measuring roller segment. Each cooling segment is composed of emulsion and control valve nozzle. The distribution of the transverse thermal expansion of the roll is changed By opening and closing the nozzle number and the injection quantity of the emulsion. Thereby the position of the corresponding strip elongation is changed. So the flatness is controlled.

Principle of stepped cooling control

Before strip enters into mill, the automatic flatness control system determines target flatness on basis of incoming conditions[3]. The various pre-set position and flatness control device is calculated. In rolling process, the flatness measurement systems continue to get the actual value of the strip-shaped plate. The actual flatness is compared with the target flatness. The deviation is the flatness adjustment error. The flatness adjustment error is used to identify flatness defects. Through the relevant mathematical model, the corresponding shape control means new settings are calculated. It is outputted to the device control system. The flatness loop control is performed.

In rolling process, pressure, tension and rolling speed can lead to warm anomalously in the direction of roll barrel length. The average diameter of the roll becomes larger. The roll shape is impacted. The changes of roll barrel flatness pass to rolled product.

The principle of stepped cooling control is to control thermal crown along the direction of roll barrel length by means of injecting roll coolant. Thermal crown of the rolls of each segment is

changed. The length of the strip corresponding to the elongation direction of the change on the segment is controlled. Ultimately purposes of strip flatness is improved.

Roll temperature field model

Roll heat transfer problems are three-dimensional heat transfer problems[4]. When the time factor is considered, it can be viewed as a four-dimensional problem[5]. In surface depth of roll, temperature cycle is changes vigorously[6]. In more than 99% of the portion of the roll, the temperature distribution is in the form of axial symmetry and fluctuations are small. So in roll temperature field research, the circumferential heat can be neglected. Three-dimensional problem is converted into a two-dimensional problem.

The relationship between rolling absorbed heat power and rolling exit temperature is:

$$N_{З} = B_i H_1 V_1 \rho c (T_1 - T_0) \tag{1}$$

Where, $N_{З}$ is the power absorbed heat rolling. B_i is nozzle open state, the central region and the edge portion of the nozzle of the nozzle area. T_1 is export rolling surface temperature. T_0 is entrance rolling surface temperature. ρ is strip density. c is strip specific heat capacity.

Roll pass this part of the heat of a thermal power is:

$$N_c = n \rho_c q \Delta T c_c \tag{2}$$

Where, N_c is coolant heat power transfer portion. n is the number of open nozzles. ρ_c is coolant density. q is single nozzle in the flow of coolant. ΔT is cooling fluid flowing into and out of the coolant temperature difference. c_c is coolant heat capacity.

Thermal diffusivity is

$$\alpha = k / cp \tag{3}$$

Where, k is thermal conductivity. c is specific heat capacity. p is density.

Two-dimensional heat conduction equations is:

$$\frac{\partial^2 \theta}{\partial x^2} + \frac{1}{r}\frac{\partial \theta}{\partial r} + \frac{\partial^2 \theta}{\partial r^2} = \frac{1}{\alpha}\frac{\partial \theta}{\partial t} \tag{4}$$

Where, θ is roll the internal temperature of each point. x is axial coordinate. r is radial coordinate. t is time. α is thermal diffusivity.

Optimum cooling capacity model

The objective function is:

$$\sum_{i=1}^{n} (Y_i - eff_i X_i)_i^2 \tag{5}$$

Where, Y_i residual flatness deviation. eff is efficacy coefficient. X_i is optimal cooling capacity

The gradient projection method is adopted to achieve the optimal cooling capacity.

Consider the problem

$$\begin{aligned} s.t.\ & Ax \geq b, \\ & Ex = e. \end{aligned} \tag{6}$$

where, $f(x)$ is differentiable function, A is $m \times n$ matrix, E is $l \times n$ matrix.

The basic idea of gradient projection method is from the practical point, searching along the feasible direction. When the iteration starting point within the feasible domain, search in the negative gradient direction. When the iteration starting point in some constraint boundary, the negative gradient is projected to nullspace of M, M is matrix structured by work constraints or row of partially work constraint gradient. It has been proved that such a projection is decreased feasible direction, and

then search along the projection direction. Therefore, Rosen gradient projection method is feasible direction method.

The computation steps of gradient projection method are as follows:

(1) Preset initial feasible point $x^{(1)}$, set $k=1$.

(2) In point $x^{(k)}$, disassemble A and b to $\begin{bmatrix} A_1 \\ A_2 \end{bmatrix}$, $\begin{bmatrix} b_1 \\ b_2 \end{bmatrix}$, make $A_1 x^{(k)} = b_1$, $A_2 x^{(k)} = b_2$.

(3) Set $M = \begin{bmatrix} A_1 \\ E \end{bmatrix}$, if M is null, make $P = I$ (unit matrix); Otherwise, make $P = I - M^T \left(MM^T \right)^{-1} M$.

(4) Set $d^{(k)} = -P\nabla f\left(x^{(k)}\right)$. If $d^{(k)} \neq 0$, turn to (6); If $d^{(k)} = 0$, turn to (5).

(5) If M is null, then stop calculating, get $x^{(k)}$; Otherwise, set $W = \left(MM^T \right)^{-1} M\nabla f\left(x^{(k)}\right) = \begin{bmatrix} u \\ v \end{bmatrix}$. If $u \geq 0$, stop calculating, $x^{(k)}$ is $K-T$ point; If u contains negative component, then select a negative component, such as u_j, to correct A_1, get rid of the row corresponds to u_j in A_1, back to (3).

(6) In order to find step $\lambda_{(k)}$, solve the following problem,: $\begin{cases} \min & f\left(x^{(k)} + \lambda d^{(k)}\right) \\ s.t. & 0 \leq \lambda \leq \lambda_{\max} \end{cases}$.

After getting $\lambda_{(k)}$, make $x^{(k+1)} = x^{(k)} + \lambda_k d^{(k)}$. Set $k := k+1$, back to (2).

Application results

The proposed stepped cooling control mathematical model has been successfully applied to a 1450mm five-stand cold rolling process control system. In order to verify its application results, the application results with stepped cooling control mathematical model is compared to the application results without stepped cooling control mathematical model. When the stepped cooling control mathematical model is not adopted, the deviation of strip flatness control is large. When the stepped cooling control mathematical model is adopted, the deviation of strip flatness control is decreased. Therefore, stepped cooling control mathematical model can increase flatness control accuracy.

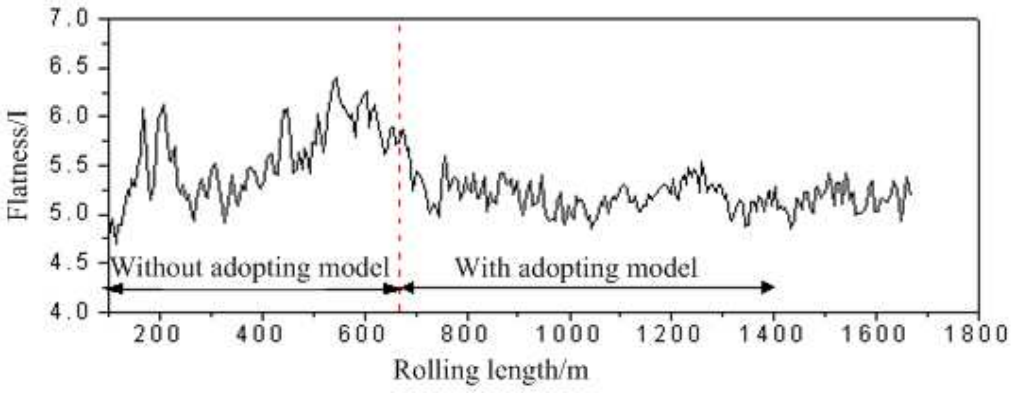

Fig.1 Strip flatness deviation comparing picture

In fig.1, when the stepped cooling control mathematical model is adopted, we can see that the flatness is good in strip. When the stepped cooling control mathematical model is adopted, we can see that it appears flatness defection.

Conclusions

(1) The impact of roll temperature to flatness is analyzed and the roll temperature field model is established.

(2) The optimum cooling capacity model mathematical model is established. The gradient projection method is adopted by the model to solve the optimal cooling capacity and the optimal cooling quality of model can decrease deviation of strip flatness control, and the flatness quality has been increased greatly.

Abstract. K-Means algorithm is a one of the most famous unsupervised clustering algorithm. It has many disadvantages, such as sensitivity to the initial clustering centers and computes all the data points multiple times when facing the increasing data volume. In order to overcome the above limitations, this paper proposes to make use of density idea to find k cluster centers by adjusting the threshold. Finally, we design and implementation of the K-Means algorithm on the modern Graphic Processing Unit (GPU). The ratio of distance between classes to distance within classes and speedup are used as evaluation criteria. The experiments indicate that the proposed algorithm significantly improves the stability and efficiency of K-Means algorithm.

Introduction

Cluster analysis is a statistical analysis method [1]. It seeks to partition a given data set into group based on specified features so that data points within a group are more similar to each other than the points in different groups. This algorithm is proposed in 1967 by MacQeen [2]. He put forward detailed steps of K-Means which had been proved by mathematical methods. The advantage of this algorithm is fast, simple and easy to implement. With in-depth study of the K-Means algorithm, some limitations are found including the interference of the initial cluster centers, converging to local optima easily and low efficacy when dealing with big data. To solve these problems, some researchers have proposed the improved heuristic algorithms. Yedla et al. [3] put forward an efficient way of assigning the data points to suitable clusters with reduced time complexity. Kang et al. [4] proposed the initial center selection method based on centrality sparsest isotropy (CSI). It can get ideal clustering results when time complexity permits. Lee et al. [5] proposed a new method. It is time-consuming, but can reduce the total clustering time by minimizing allocation and recalculation.

In view of the parallel algorithm under big data circumstance, Bai et al. [6] proposed a novel single instruction multiple data (SIMD) architecture processors (GPUs) based K-Means algorithm. Both the data objects assignment and k-centroids recalculation are offloaded to the GPU in parallel. Li et al. [7] use two different strategies for low-dimensional data sets and high-dimensional data sets respectively to make the best use of GPU computing horsepower. Kijsipongse [8] employed the dynamic load balancing to distribute workload equally on different GPUs installed in the clusters and improve the performance of the parallel K-Means at the inter-node level.

In face of problems existing in traditional K-Means algorithm and the explosive growth of data, we propose an improved GPU-based K-Means algorithm. We found *k* relatively dispersed samples as the initial cluster centers to increase the possibility of finding the global optimal solution. Combining GPU architecture platform we improved the efficiency of the algorithm.

The paper is organized as follows. Section 2 presents the related literature on CUDA and K-Means algorithm. Section 3 discusses the initial cluster centers selection algorithm and the GPU-based K-Means. The experimental results are provided in Section 4. Finally, Section 5 concludes the paper.

Related Technologies

Partition-based clustering algorithm. There are a lot of clustering algorithms in literature. K-mean algorithm is one of them. It is a process of grouping data objects into different clusters so that the data in each cluster are similar, yet different to the other clusters. According to the basic principles of the clustering algorithm, K-Means algorithm is provided as below:

1. *k* initial clustering centers are chooses from the dataset randomly.
2. For each point, calculate the distance to all clustering centers, and assign it to the nearest one.
3. Recalculate the new cluster centers by the average of all data that are assigned to the clusters.
4. Repeat step 2 and 3 until convergence.

CUDA Model. GPU is a specialized hardware initially used to accelerate calculations for 3D computer graphics. NVIDIA Corporation (NVIDIA) officially released with Compute Unified Device Architecture (CUDA) in 2007. CUDA is a programming of heterogeneous systems, i.e. the hybrid of CPU and GPU. The key point of CUDA model is to take CPU as the host to process logic and transactional program, while the GPU works as a coprocessor to process highly parallel procedures. Generally, CUDA is collectively composed of two processes: the serial process executing control function by CPU and the parallel process executing kernel function by GPU. GPU is not suitable to compute complex data structure while it can do a large amount of same pattern calculation.

CUDA computing core is composed of Stream Multiprocessors (SMs) with eight Stream Processors (SPs) in each SM. Five types of GPU memories are supplied to take advantage of the flexibility to develop efficient coding. This memory structure is directly exposed by the CUDA programming framework. In general, accessing the largest type of memory is flexible but slow, while accessing the smallest type of memory is restrictive but fast. Among the five types of memories, registers are fastest while global memory is slow. Shared memory is as fast as register, but it may have bank conflicts if the threads are badly assigned. The challenge in mapping a computing problem efficiently on a GPU through CUDA is to store frequently used data in the fastest memory.

Proposed methodology

The Selection of Initial Center Points. The traditional K-Means algorithm is sensitive to the initial cluster centers and liable to converge to a locally optimal solution. Meanwhile, the sensitivity to the outliers leads to inaccurate clustering results. So we propose a variable threshold based on density K-Means algorithm to solve this limitation. We use the Euclidean distance as the distance function. Specific procedures for the selection of initial cluster centers algorithm are as follows:

Data description: *k*, number of clusters; *t*, threshold, i.e. the selected radius; *w*, density, i.e. the number of data points within the circle radius *t*; *M*, the set of all points; *s*, a very small value.

1. Choose the distance between the first two points in *M* as *t*.
2. Choose the point $x_i (x_i \in M)$ which has the maximum density as the initial center point v_1. Calculate the density u_i within the *t* distance of all points in *M*, the mean density $\mathrm{w} = \sum_{i=1}^{n} u_i / n$ is taken as a point of reference density. Finally, all points in *M* whose distance to v_1 are less than *t* are deleted.
3. Choose the points in *M* that their distance between each other is beyond *t* as the initial centers. These points meet the condition that their distances to v_1 are $\mathrm{d2} = 2 \cdot \mathrm{t} + \mathrm{s}$ and their density are greater than *w*. The points in *M* which distance to v_1 is less than $\mathrm{d1} = 2 \cdot \mathrm{t}$ are deleted.
4. Set $\mathrm{d1} = 2 \cdot \mathrm{t} \cdot \mathrm{i}$ and $\mathrm{d2} = 2 \cdot \mathrm{t} \cdot \mathrm{i} + \mathrm{s}$ where *i* is the current number of loops. Repeat step (3) until *M* is empty. *i* is incremented by one in each iteration. Then go to step (5).
5. When *M* is empty, we can decide whether the number of center points is *k*. if yes, *k* center points are found. If it is larger than *k*, *t* is replaced by a bigger number and back to step (2). If it is smaller than *k*, *t* is replaced by a smaller number, then go back to step (2).

K-Means Algorithm Based On GPU. The main idea of the GPU-based K-Means algorithm is to make the data independent, and transfer the intensive calculation from host to device to improve performance. It can be seen that the main computational tasks are concentrated in step (2), (3) during

the whole algorithm process. Although these two steps will be performed many times, data points for each calculation are independent. Thus, they can be separated into two kernel functions and the data can be paralleled computed by the GPU core. In this way, we optimize the GPU-based K-Means algorithm in step (2) and step (3).

Currently, since a GPU has more than 100 processing cores, data points can be operated in threads within these cores. In each thread, distances from each data point to all the cluster centers are calculated. According to the distance, data points will be assigned to the nearest cluster. In CUDA architecture, shared memory is fast and has larger storage capacity than register. We can take the center points to shared memory to reduce the delay instead of those in the global memory. Meanwhile, k cluster centers can also be calculated by GPU, and each calculation is operated by a thread in CUDA. The new cluster centers are calculated by the arithmetic mean of all data points in original clusters. In GPU, if a large number of threads simultaneously access the same place in shared memory, it will lead to significant delay. Therefore we make the k threads access order position in shared memory simultaneously and add the data which belongs to this cluster. Then they access the next position orderly until all data points are accessed. When the new cluster centers in each cluster are calculated, the results will be sent to the global memory and wait for the next iteration.

Experimental results and discussion

Experimental setting and evaluation criteria. All experiments are implemented on MATLAB and Visual Studio. The test system is a PC with an Intel Core 6 Exon 2620 CPU. The GPU is an NVIDIA Tesla k20 with 2496 stream processors and CUDA is the 5.5 version.

In order to validate the accuracy and efficiency of our proposed algorithm, we select seven data sets (Iris, Libras, Yeast, etc.) from UCI database. To verify the accuracy and effectiveness of the improved algorithm, we test for 15 times on the traditional K-Means and improved algorithm. We adopt the ratio of between class distance to within class distance as the criteria. The within class distance is the average value of the distance between mean point and each object in the same cluster. The distance between classes is determined by the average value of distance between any two mean points of clusters. The smaller the ratio is, the better the clustering result is. Then the speedup is compared to test the effectiveness. The larger the speedup is, the better the efficiency is.

Analysis of results. This section implements the improved K-Means algorithm. The algorithm is tested in the seven datasets. Table 1 shows the experimental results for the initial center selection algorithm based on five datasets. It can be seen that the ratio of the proposed algorithm is less than that of the traditional K-means algorithm. Fig 1 gives the visual representation of results. In order to present clearly, we scale all values to range of 0-1. Clustering results of our algorithm are stable and overcome the limitations including selecting center points randomly in the K-Means algorithm. Seeing from the characteristics of data sets, our proposed algorithm has good performance on a variety of data sets and it is less affected by the number of samples and properties.

Table 1. The ratio of within class distance and between class distance

DataSet	# of records	# of attribute	K-Means	Improved K-Means
Iris	150	4	0.2503	0.1672
Libras	360	90	0.5063	0.3952
Yeast	1480	8	0.1262	0.0809
Synthetic_control	600	60	17.8281	13.778
Water-treatment	527	38	186.6086	154.0504

Table 2 and Figs 2 show that GPU can accelerate K-Means algorithm. The speedup ratio are different according to the size of data sets, data dimensions and presented characteristics. In the case of small size of data set, the speedup is not obvious due to the delay of GPU memory copies, starting up of device and data-completion.

Table 2. Running time comparison

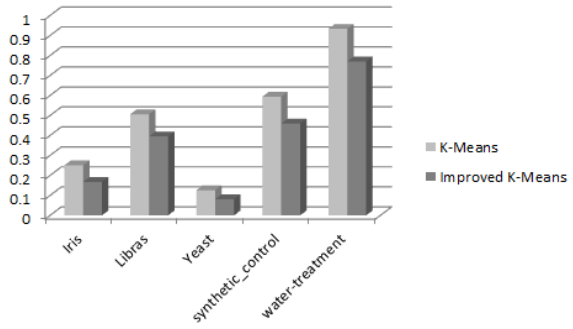

Fig. 1 The ratio of within class distance and between class distance

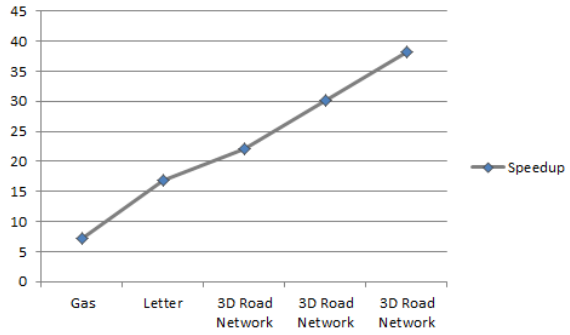

Fig. 2 Speedup with GPU

Summary

This paper analyzes the limitations of the traditional K-Means algorithm based on numerous studies by many researchers. Then the improved K-Means algorithm is proposed.

1. It can overcome the sensitive issues of initial centers selection and the impact of outlier points.
2. With the introduction of a parallel way, the K-Means algorithm is optimized on GPU.

According to tests, the proposed method can improve the stability and efficiency significantly on a single machine.

Keywords: Image segmentation; Iterative erosion; Embedded system; OPENCV

Abstract. The fast image processing based on iterative erosion principle can complete separation of colony image of adhesion target quickly. This algorithm is composed of local threshold method of image binarization; the morphological processing, analyzing; removing the edge based on Hough Transform and using improved iterative erosion algorithm to adhesion target segmentation and counting. The algorithm has scale invariance and self-adaption for recognition different size colony target. The conditional expansion algorithm designed in the paper can effectively modify the count mistakes which are caused by fragments formed by the segmentation of large size targets in the iterative and erosion processes. The algorithm has been applied in portable colony counting instrument on ARM11 embedded platform. Twenty heterotrophic bacterial samples have been tested in experiments. The results show that this algorithm can realize the image segmentation rapidly and effectively and the time of analysis is less than 2 seconds. The images edge detection rate can reach 100%. The detection accuracy can get the requirements of GB 4789.2-2010 and achieve deviation of 3% in colonies' total number less than 300CFU.The applied of algorithm is widely in the similar particle image analysis system.

Introduction

With the development of image analysis technology , automated analysis of all kinds of images as cells and plant seeds has become study focuses in recent years[1-2]. The detection of colony amount is a critical health index in agriculture, food , medicine and health industries. In domestic area, the colony detection currently still relies on simple manual detection. While most of the automated counters in market are running on desk computers, it's still difficult to reach real time and portability. It's a development trend to explore a portable detector by applying ARM platform combined with embedded technology. As identifying and counting colony individuals both depend on colony image segmentation, the problem of which lies in the difficulty caused by colony adhesion, it's also the core issue supposed to be solved in the development of automated analysis system.

The task of colony image segmentation is to mark and locate the target as well as the background based on image priori knowledge and separate it from background or phony targets[3-5]. The methods of colony image segmentation at home and in abroad generally adopted are threshold comparison, clustering analysis and morphologic segmentation etc[6-8]. Due to the elaboration and complexity of traditional colony image segmentation algorithm, it is hard to be applied in an embedded and automated analysis system. We studies about extracting image edges with a comprehensive usage of Hough Transform and complete image segmentation through combing improved iterative erosion algorithm of conditional expansion and extreme erosion, meanwhile realizing high counting accuracy with programming optimization on the basis of this algorithm design.

Material and method

A Image binarization and edge detection

We complete image binarization and edge detection firstly. Image binarization usually takes threshold segmentation method. To choose the segmentation method and threshold both are based on the analysis of image grayscale distribution[9-10]. There should be morphologic 'closing' settlement

after the threshold segmentation to bridge narrow gaps and spindly ditch, remove small holes and fill up the contour fracture. This operation is defined as

$$A \bullet B=(A \oplus B) \ominus B \quad (1)$$

A and B respectively stands for target image and the structural element.

We use Hough Transform to detect the binary image's edge. The Hough Transform takes advantage of the whole image to link edge pixels of the target as to form a closed boundary of target region or directly detect the targets of known shape among images. Image edges in the paper are normally known as circle, so Hough Transform is suitable for edge detection[11].

B Iterative erosion segmentation

Iterative erosion algorithm consists of two basic algorithm operators in mathematic morphology:

erosion and expansion, and is built upon conditional expansion and extreme erosion that can quickly cluster and segment images.

Conditional expansion is a type of limited expansion, usually constrained in a limited set X within which the expansion is conducted like Eq.2.

$$f'=(f \oplus b) \cap X \quad (2)$$

f indicates the structural element and b indicates the expansion template.

Extreme erosion refers to a repeated erosion of one target till it disappears and to keep the result before last erosion. This result is regarded as a target seed:

$$f_k= f \ominus kb \quad (3)$$

b refers to the erosion template while k to the erosion times. The final seed point of the target g_k is an element in f_k..

In iterative erosion algorithm, extreme erosion is followed with conditional expansion every time. The target seed will be got by comparing the image now and before latest erosion and expansion.

Taking the twice iterative erosion as example, as shown in Fig.1, the steps of iterative erosion is expressed as below:

Step1. Erosion

$$f_1= f \ominus b \quad (4)$$

As in Fig.1a, image template used for erosion is shown in Fig.1b with a result after erosion indicated in Fig.1c

Step2. Conditional expansion

$$U_1=(f_1 \oplus b) \cap X \quad (5)$$

Use the template to expanse the erosion result. Fig.1d is what it is like after expansion through template b

Step3. Deduction

$$g_1=U_1 - f_1 \quad (6)$$

Deduct the once erosion and expansion result from the original image to get a target seed point. Two seed points are completed by deducting Fig.1d from Fig.1a. Then follows the steps above.

Step4. End

$$f \ominus 3b = \Phi \quad (7)$$

The algorithm ends when the three times erosion is a null set and erosion of twice is also a target seed point.

Step5. A union set of multiple targets in an image is the final erosion target set g.

$$g=g_1 \cup g_2 \cup f_2 \quad (8)$$

f refers to the original image element, f_k stands for the erosion result of k^{th} time. b refers to the algorithm template while U_k indicates expansion result of k^{th} time. g_k stands for the k^{th} seed points and g for the set of final seed points.

The iterative erosion algorithm not only can segment adhesive targets effectively, but also reduce the errors from different settings of initial points to accomplish precise and quick segmentation. As the target shapes are unlikely to be standard convex set, the image obtained after the iterative erosion contains both colony seed points that are completely corroded and some pieces corroded from larger size colony. This will lead to a repeat count of the same colony and impact the accuracy. In order to

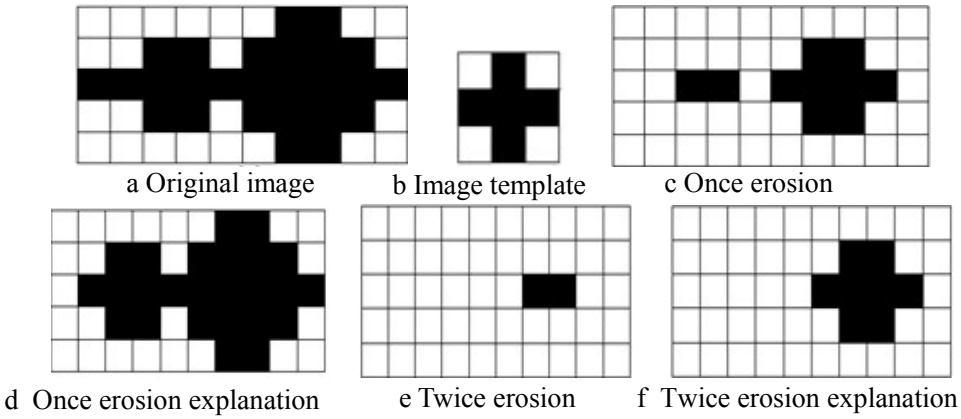

Figure.1 The diagram of twice iteration erosion

eliminate these pieces, the iterative erosion algorithm needs to improve as the conducting several conditional expansion toward the result after erosion is finished so that the pieces can be adhered as much as possible.

Result and discussion

To test the actual effect of automated and fast segmentation of iterative erosion algorithm, OPENCV computer vision is used on the basis of AMD 2.9GHz，2GB computer to develop the embedded core intelligent counting algorithm of colony based on Windows CE6.0. A wild-field infrared CCD camera is adopted as video collection device to test the accuracy of segmentation algorithm via comparison between automated counting result from this algorithm and manual counting result.

The experiment sample comes from many monitoring points of industrial wastewater in recycle stations in Tianjing, Qiqihaer, Mudan rivers. Taking the national standard testing method--common nutrition agar poured into flat petri dish for colony vaccination counting[12]. The automated segmentation counting algorithms of colony images include steps like image preprocessing, threshold segmentation, petri dish edge removing, image segmentation and colony marking. The procedures are indicated in Fig.2. The median filter parameter is set as 3, while Gaussian Filter size as 5 and the processing result is shown as Fig.3c.

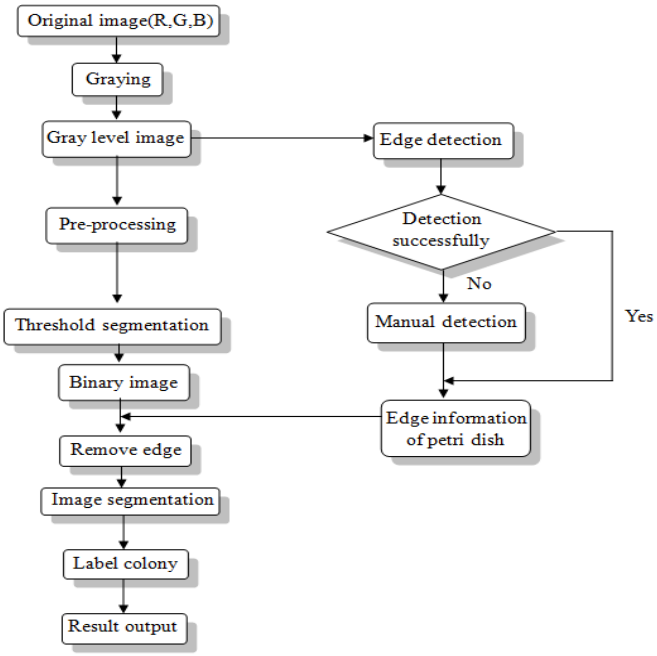

Figure.2 The flowchart of intelligent bacterial colony counting algorithm

a Original image b Gray level image c Image of filtering

Figure.3 Image grayscale and preprocessing

Fig.4 shows that in the histogram distribution of image gray, the bimodal trend is not obvious so partial threshold segmentation is the best.

Select appropriate threshold T for partial threshold binarization of the image. Taking the average value of pixel gray in the counting window of window template with moderate offset (set it 10 according to experiment verification) as the center pixel threshold of this window. Processes image is shown in Fig.5a. An operation of morphologic 'closing' is made after image binarization to fill up 'cracks' and 'holes' that occurred in larger size colony in the image, effect as Fig.5b shows. Choose erosion and expansion templates to treat the image with improved iterative erosion, erosion effect as Fig.5c indicates.

Detect the edge of petri dish based on Hough Transform principle and the effect is presented in Fig.6a.Label the image according to recursion notation with the result expressed in Fig.6b. Invoke the search function to label and search. As search is finished, feature points in the same connected domain are saved in the same array to complete colony counting.

12 colony images of the same size are detected for the edge and is compared to the actual circle center and radius of the petri dish. Edge detection success rate reached 100% with detection error of circle center location and radius size of the petri dish controlled within 3 pixels (0.6%). A sound effect is indicated in Table 1.

The algorithm in this paper is used for massive experiment of automated counting of colony images, which are compared with the result of traditional manual counting and the outcome is expressed in Table 2. What needs to be illustrated is that the manual counting result we selected came

9	277	290	4.7%	19	802	876	9.2%
10	294	282	4.1%	20	986	907	8.0%

from the average value of the same sample counted by 3 detectors respectively and the error of three manual counting is below 10%.

From Table 2, the average error between automated counting and manual counting is within 6 % with 9.6% as most and 1.3% least. Among them, sample colony less than 300 is below error of 5% and the average error is 3.0% while the average error of colony more than 300 is 7.3%.

In the perspective of speed, this algorithm of automated counting based on desk computer can finish counting 300 colonies in 500 milliseconds. If the algorithm is transplanted to the core of embedded system of Windows CE 6.0 for automated counting, the speed counting 300 is less than 2 seconds.

Conclusion

Traditional image segmentation algorithm such as wavelet and neural network has involved a great deal of floating-point arithmetic that is highly complicated and time consuming. The iterative erosion algorithm studied here, by graying the image collected, segmented the threshold of the image with partial threshold method. It used multiple iterative erosion algorithm for segmentation of adhesive targets based on Hough Transform to remove the image edge. Finally, recursion notation is adopted to label the connected domain and accomplish target counting. As this algorithm is a massive logic algebraic calculation (mainly location comparison and evaluation) on the basis of image binarization, it calculates less and quite suits for operation on embedded instrument terminal with limited calculation capability. The previous experiment result indicated that this algorithm is able to complete fast image segmentation while ensuring the accuracy. It boasts advantages of speed, ease and accuracy on colony image segmentation and automated labeling and counting of images and the counting result is free from the influence of colony pattern, size and vaccination method[13]. In addition, this algorithm is also widely applied in automated counting instrument of other microbes with a promising future.

A Semantic Retrieval Method Based on Ontology[1]

Qi Shen, Meng Zhang

School of Software EngineeringBeijing University of Technology, Beijing, China

shenq@bjtu.edu.cn, zhqmflag-2005@163.com

Keywords: ontology; concept similarity; weight; semantic expansion.

Abstract. Semantic retrieval method stands at the crossroads between Natural Language Processing and Machine Intelligent. This paper makes analysis on the semantic search method and research on concept similarity algorithm, and discusses the factor of weight's influence on concept similarity as well. On this basis, this paper proposed a new semantic search method based on ontology, and apply it to the tourism information retrieval, which intellectualized tourism information retrieval service.

1. Introduction

With the rapid development of Internet and mobile communication technology, Web has become a source of global information, how to find the needed information quickly and accurately from the vast information resources becomes a difficult problem for the user. The traditional information retrieval method provided to the users is matching search according to the keywords input by users. But in majority of cases, it is difficult to understand users' real purpose by these simple keywords matching search which leading to the low accuracy of current information retrieval.

Some experts abroad have conducted practical operation based on ontology, such as the Ontoseek directory system which retrievaling based on content, it integrates the product tree structure and online yellow pages. It is said that formal ability and body content matching mechanism are combined, and the ontology and database dictionary together, provide the user a can input natural language, and then into the domain ontology vocabulary, semantic retrieval system[1]. We can learn from Ontoseek pages in the system, the relationship between the concept of vocabulary and vocabulary which is not subject to any constraints, so the relationship between the vocabulary may not play any role, therefore will occur the retrieved results are not required by the user. Tourism yellow page service system at present, such as "Ctrip", "road ox net", in the search for a keyword input by the user information only for the simple matching words, do not understand the user input information on the semantics, also cannot be well retrieved information the user really need. Therefore, must the information retrieval from the existing keyword matching level to understand the knowledge level, semantic level to the information and expression based on them, so as to design a user can understand the semantic information retrieval model[2].

2. The Semantic Search Method based on Ontology

The basic idea of semantic retrieval algorithms extend is that through calculating semantic similarity of the input keyword to get a similarity value and then add the concept of greater than the threshold value to form a new set as new keyword to retrieval[3].

A. The Concept Similarity

Concept similarity refers to the semantic closeness of two concepts. Under the support of Ontology, there are three models to calculating the conceptual similarity as following:

1) Distance Model

Constructed ontology forms tree structure. With the ade of this structure, distance model matches the keyword to the corresponding nodes in the tree body of ontology[3]. The similarity between the two concepts is measured by the distance between two nodes of the tree. For simpicity on practice,

it adopts a simple calculation: that takes the distance between every two nodes in the tree body of ontology having the same length, quantize as 1 for example. Therefore the shortest distance of two nodes on the ontology tree equals to the semantic distance of these two concepts[4]. The concept similarity is calculated as follows:

$$Similar(x_1, x_2) = \frac{2 \times (Maxlen - 1) - Min}{2 \times (Maxlen - 1)} \tag{1}$$

Wherein: MaxLen refers to the depth of the ontology tree, Min refers to the shortest distance between the concept nodes x_1 and x_2. Obviously the above formula is very simple, and the very conceptual similarity is not precise.

2) Information Quantity Model

The quantity of information possessed by the conceptural tree nodes refers to the capacity of the concept content. The greater intersection of two concepts nodes contained on content the higher semantic similarity between them is, on the contrary lower similarity[5]. In the ontology tree structure, each node concepts are seen as inherited from its parent node, so each node in the tree can be seen containing the approximately equivalent quantity of information as their parent nodes. Therefore, the extent of the similarity of any two concepts in the ontology tree nodes can be replaced by caculating the capacity of its respective closenest parent nodes[6]. The fomular of calculating information quantity owned by the concept nodes:

$$p(x) = \frac{f}{\mathrm{m}} \tag{2}$$

$$DC(x) = -\log[\mathrm{p}(x)] \tag{3}$$

Among them, F represents the number of x appeared in training resources. M represents the total number of concepts in training resources. p (x) represents to the probility of node concept x appeared in the constructed ontology repositories; DC (x) represents carrying out processing log on the probality of the node concept appeared in the ontology repositories. Based on the quantity of information contained by the concept node, revealed the following formular about the concept similarity in the ontology tree structure:

$$Similar(x_1, x_2) = \frac{2 \times DC[Ancestor(x_1, x_2)]}{DC(x_1) + DC(x_2)} \tag{4}$$

Wherein: $Ancestor(x_1, x_2)$ is the information quantity contained by the parent concept nodes nerest to concept nodes x_1 and x_2 in the ontology tree structure.

3)Property Model

In the process of comparing the similarity or closeness between two things, it is typical to analize their properties or characteristics[7]. The similarity of node concept in the property model based on the concept node can be calculated as follows:

$$Similar(x_1, x_2) = f(x_1 \cap x_2) - f(x_1 - x_2) - f(x_2 - x_1) \tag{5}$$

Wherein: $x_1 \cap x_2$ said the intercecton of properties between node concept x_1 and x_2, the $x_1 - x_2$ represents the number of properties attribute to node concept x1 while are not included in the node concept x_2, $x_2 - x_1$ means the number of properties attibute to node concept x_2 while are not included in the node concept x_1.

B. Weight

Weight refers to the value given to the distance between the connected concept nodes. The size of the given weight can impact the concept similarity; this paper makes analysis on three major factors that affecting the size of weight as following:

1) Property Type

The value of weight given to the distance connected concept nodes holding different type of properties in the ontology tree structure should be different. If the property of the concept node is synonymous, such as in the field of tourism the ontology properties of two node concpts connected by "SynonymsIs" is synonym, so the weight value given to the synonyms should be higher than the weight of the other several types of properties weights. Therefore, according to common sense, the weight given to the edges with "inheritance" property is usually higher than that given to "whole-part relationship" poperties. So ultimately formed the relationship between property types and weights:

$$weight(x,y)=\begin{cases}1, type(x,y)=SynonymsIs;\\ 0.5, type(x,y)=IsExtend;\\ 0.3, type(x,y)=IsPartOf;\end{cases} \tag{6}$$

Weight(x, y) refers to the weight given to the edge containing certain type of property formed by the node concept x and its parent node y. The size of the value in formula (6) is defined by the ontology builder. These people all have a deep understanding on the concept and terminology of this field. The weight caculating formula reflects the relationship between the property type and size of the weights.

2) The Depth of Edge

Nearer to the leaf, the nodes contain more detailed information. On the reverse, node in the tree root represents less specific information. So, the size of the weight given to the edge is closely related to its level in the tree structure. This hierarchy represents the depth of the edge. Therefore, it is concluded the relationship between the depth of the edge and the weight:

$$weight(x,y)=(\frac{1}{2^{depth(y)}}+\frac{1}{2^{depth(y)-1}}+...+\frac{1}{2}+1)=\sum_{n=0}^{depth(y)}\frac{1}{2^n} \tag{7}$$

Among them, $depth(y)$ refers to the depth of concept node y in the tree. Formula (7) well embodies the relationship between depth of ontology tree edges and the size of weight: the size of weight given to the edge is directly proportional to the depth of nodes in the tree.

3) The Intersection of Properties

For the concept nodes in one edge with certain property, the more same properties they contained shows the more common characters they have, therefore the two concepts are more similar. The weight given to the edge connected by the two concepts node through the property also should be bigger. As a result, the relationship between the sizes of intersection set of two concept nodes' properties and the weight:

$$weight(x,y)=\frac{count(A\text{ssemble(x)}\cap A\text{ssemble(y)})}{count(A\text{ssemble}(x)\cup A\text{ssemble}(y))} \tag{8}$$

Assemble(x) and Assemble(y) are on behalf of the property set of concept node x and property set of concept node y; $A\text{ssemble(x)}\cap A\text{ssemble(y)}$ are on behalf of the properties intersection of concept nodes x and concept node y; $A\text{ssemble(x)}\cup A\text{ssemble(y)}$ are on behalf of the properties union of concept nodes x and concept node y; and count () function is on behalf of the number of properties in the relative property set.

C. Semantic Expansion

Through analysis of the concept similarity in the ontology tree structure, and several factors affecting the weight as well we proposed the improved semantic expantion retreval algorithm. The distance formua inserted weights asfollowing:

$$Distance(a,b)=N[a,Ancestor(a,b)]+N[b,Ancestor(a,b)] \tag{9}$$

$$N[b,Ancestor(a,b)]=\sum_{x\in path(a,Ancestor(a,b))} Distance(x,Parent(x)) \tag{10}$$

$$Distance(x,Parent(x))=\frac{\alpha}{weight(x,Parent(x))}-\alpha \tag{11}$$

$Ancestor(a,b)$ represents the nearest common ancestor node of concept node a and concept node b in the tree structure; $path(a,b)$ refers to the set formed by all the concept nodes in the shortest path between concept node a and concept node b of the tree stucture in the field of ontology. α is an adjustable factor. Formular (11) represents the distance between the child node and the parent node. Thus, under the condition of knowing the distance between arbitrary two nodes in the domain of ontology tree structure, we concluded the similarity calculation formula between any two concepts:

$$Similar(a,b)=\frac{\theta}{Distance(a,b)+\theta} \tag{12}$$

θ is an adjustable parameter. The formula shows the relation between arbitary two ontology semantic similarity and the two concept nodes: When $Distance(a,b)=0$, indicating that the value of the denominator is small, but the degree of similarity is greater, so the concept node a is similar to concept nodes b. The maximum value of concept similarity is up to 1; then when $Distance(a,b)=\infty$, the value of the denominator is large, the value of similarity is very small, so the concept node a and node b hardly have any relation, the minimum value of concept similarity is down to 0.

Formula (12) shows that the value of the concept similarity forms a closed interval from 0 to 1, in this article we set the threshold as 0.7, when the value of the concept similarity is greater than 0.7, the similarity of the two concepts can be considered relatively high, and then extend this concept into a more comprehensive, updated search term

3. Application in Tourism

The proposed retrieval method in this paper is applied to the Beijing tourism resources retrieval, all experimental data are retrieved from the ontology library, the library is artificialy classified first, and then taking use of reptiles tools to crawling tourism data from the Internet. the data in the repository is web data captured through a web crawler. To facilitate the calculating results, we set the amount of resources of each classified information to 1000, and relative resources for retrieving to 100. For example: we set a total of 1,000 hotel information resources, and for those near the Beijing University of Technology are100. Thus retrieve information about the following three statistics, namely: to retrieve the bus information, retrieve hotels near the attractions, retrieve sites nearby attractions.

Retrieval results shows that there are 82 relative resources about No. 52 bus, 144 were retrieved. The number of relative hotels near Beijing University of Technology is 85, 130 were retrieved. The number of Attractions near Tiananmen is 93, 155 were retrieved. The charter below shows the recall ratio and precion ratio between the retrieval method employed by the Ctrip and semantic retrieval method:

Table 1 Semantic search method compare with Ctrip counterpart

Retrieval System	Sort	Bus inquiries	Attractions near the hotel	Attrations nearby station inquiry
Ctrip	Recall ratio	45%	55%	50%
	Precision ratio	30%	50%	40%
Semantic Retrieval	Recall ratio	82%	85%	93%
	Precision ratio	57%	65%	60%

On both recall ratio and precision ratio, the semantic retrieval method proposed in this paper is higher than the trational tourist website represented by Ctrip. From data displayed in the above chart

we can drawn a conclusion that with the support of ontology technology, both the recall ratio and precision ratio are improved.

4. Conclusion

The purpose of applying semantic retrieval is to achieve computer's understanding about the user input content to process retrieval on semantic level . Bearing on the concept similarity and its three caculating methos, this paper introduces the concept of weight and its caculating formula. Based on the analysis of combining concept similarity and weight, this paper proposes a semantic search method based on ontology and applied this method in to tourist information retrieval. This paper also evaluates the result of retrieval from the persepect pf recall ratio and precision ratio which validated the effectiveness of the algorithm.

Keywords: support vector machine, estimation, chlorophyll concentration, rice, hyperspectral remote sensing

Abstract. This study focused on estimating chlorophyll concentration of rice using PROSPECT and support vector machine. The study site is located in West Lake sewage irrigation area of Changchun, Jiliin Province. Reflectance spectrual of rice were measured by ASD3 spectrometer, chlorophyll contents of rice were recorded with a portable chlorophyll meter SPAD-502. Support vector machines and PROSPECT model were adopted to construct hyperspectral models for predicting chlorophyll content. The results indicate that: the hyperspectral prediction model of rice chlorophyll content yields a maximum correlation coefficient of 0.8563, and achieves a smallest RMSE of 9.5106; and the prediction accuracy based on the first derivative spectrum is higher than on the original spectrum. Research of this paper provides a theoretical basis for large scale dynamic prediction of rice chlorophyll content in sewage irrigated area.

Introduction

Rice is an important crop in China, many farmers choose the untreated sewage as rice irrigation water in some suburbs of northern city. The sewage irrigation water contains heavy metals, which will directly affect the rice physiological process, and hinder chlorophyll synthesis. Study on chlorophyll content estimation of sewage irrigation area has important implications for the monitoring of heavy metals for the stress of rice.

In recent years, estimating chlorophyll content of plants from the spectrometer and satellite hyperspectral remote sensing technology has been investigated. The related research trend is mainly in two aspects. On the one hand, the use of statistical models for estimating chlorophyll content of plants[1-6]; on the other hand, is the inversion of radiative transfer models for chlorophyll content[7]. However, less research focused on estimating chlorophyll concentration using PROSEPCT and support vector machine. This study intends to construct spectral inversion model of rice based on support vector machine and PROSPECT model, so as to monitor these wage irrigation areas rapidly using hyperspectral remote sensing technology.

2.Materials and methods

2.1 Field experiment

The study selected sewage irrigation farmland located at Changchun City, Jilin Province, China. There is the FAW factory near West Lake, resulting in long-term groundwater contamination around West Lake. Two rice samples fields in the study area was selected, rice spectral data was collected and chlorophyll content in rice was measured .

2.2 Data preparation

Hyperspectral data of rice was collected by ASD3 field spectral radiometer, which spectral range was between 350-2500 nm. The radiometer was set to 25° viewing angle, and reflectance spectra of 400-1250 nm was adopt for the study.

Chlorophyll content in Rice was measured by SPAD-502 hand-held chlorophyll meter, each rice plants was measured 10 leaf chlorophyll values ,and taking the average value.

2.3 Spectral transformation method

Spectral differential transformation can increase the spectral irradiance spectrum at different wavelengths, thus sharpening the spectral information. First order differential transform can provide the change rate of steep spectrum information, and it can reduce the influence of noise spectrum by the environment, so as to enhance the hyperspectral data. First order differential transform were performed on spectral reflectance of rice.

2.4 PROSPECT model

The PROSEPCT model simulates leaf transmittance spectra and leaf reflectance spectra by the relationship between four parameters, they are: the leaf structure parameter (*N*), the content of dry matter *Cm* ($g\,cm^{-2}$), equivalent water thickness (cm or $g\,cm^{-2}$), chlorophyll content (Chla and Chlb).

2.5 Support vector machine regression

Support vector machine regression has been applied classification and estimation. Support vector machine regression model were introduced as follows:

A nonlinear mapping $\phi(x) = \{\phi(x_1), \phi(x_2), ..., \phi(x_i)\}$ is used to map the training data set into a high dimensional feature space $T = \{(x_1, y_1), ..., (x_i, y_i), ...(x_N, y_N)\}$, where exists an optimization function *f* to connect the input data and output data. The optimal decision equation, namely support vector machine regression equation, is introduced as follows:

$$f(x) = w^T \varphi(x) + b \tag{1}$$

where f (x) is the estimation value, coefficient $w(w \in \Re^{nh})$ and $b(b \in \Re)$ can be adjusted. The goal of support vector machine is to minimize the training error with insensitive loss function:

$$R(f) = \frac{1}{N} \sum_{i=1}^{N} |y_i - f(x_i)| \tag{2}$$

By defining $v_\varepsilon(y_i, f(x_i)) = Max\{0, |y_i - f(x_i)| - \varepsilon\}$ as the ε-insensitive loss function, ε-insensitive loss function is often used to control the sparseness and generalization ability of the model. Thus, the support vector machine regression is focus on the training error optimal hyperplane and the minimization of the training data set between the ε-insensitive loss function. Thus, the goal of support vector machine is to minimize the overall error of regression:

$$Min\ R\varepsilon(w, \xi_i, \xi_i^*) = \frac{1}{2} w^T w + C \sum_{i=1}^{N} (\xi_i^* + \xi_i) \tag{3}$$

with the constraints

$$w^T \varphi(x_i) - b + y_i \le \varepsilon + \xi_i^*, i = 1, 2, ..., N$$

$$-y_i + w^T \varphi(x_i) + b \le \varepsilon + \xi_i, i = 1, 2, ..., N$$

$$\xi_i, \xi_i^* \ge 0, \qquad i = 1, 2, ..., N$$

where the minimization function is used to punish the greater weight, used to maintain the smoothness of the regression function. The second formula use the ε-insensitive loss function to regulate the pipe reliability risk and the empirical risk. *C* is a parameter to balance these two formulas. Training errors above ε are denoted as ξ_i^*, whereas training errors below -ε are denoted as ξ_i.

After the optimization problems solved by constraint, the parameter vector *w* obtained:

$$w = \sum_{i=1}^{N} (\beta_i^* - \beta_i) \varphi(x_i) \tag{4}$$

where β_i^* and β can be solved through quadratic program, namely Lagrange polynomial. Finally, the support vector machine regression function can be obtained in dual space:

$$f(x)=\sum_{i=1}^{N}\left(\beta_i^*-\beta_i\right)k\left(X_1,X\right)+b \tag{5}$$

where $K\left(X_i,X_j\right)$ is the kernel function, it is the inner product of two vectors (X_i and X_j), and in the feature space $\varphi(x_i)$ and $\varphi(x_j)$, the kernel function is equivalent to $K(x_i,x_j)=\varphi(x_i)\times\varphi(x_j)$.

The Gauss radial basis function (RBF) as the kernel function of support vector machine regression was adopted. Estimation model of chlorophyll content of rice in the sewage irrigation area were based on support vector machine, where there are two important parameters affects the precision of the model: including the parameter C and Gauss parameter σ of RBF kernel. Grid search method was applied to optimize the regression parameters of support vector machine.

3. Results

3.1 Selection of SVR parameters

The parameters of support vector machine regression determined by grid search was shown in Table 1, λ denotes for rice original spectral data set, $FD\lambda$ denotes for the spectral data set after a derivative transformation. Parameter C and kernel parameter σ on the $FD\lambda$ data set are smaller than the original spectral data sets, and the computing time of support vector machine regression on on the $FD\lambda$ data set is less than in the original spectral data set.

Table 1 Parameters of SVM selected by grid search

Spectral data set	parameter C	Kernel parameter σ	Time (s)
λ	98.7632	956.3578	1408
$FD\lambda$	97.3653	56.6457	1353

3.2 Estimation result of rice chlorophyll content

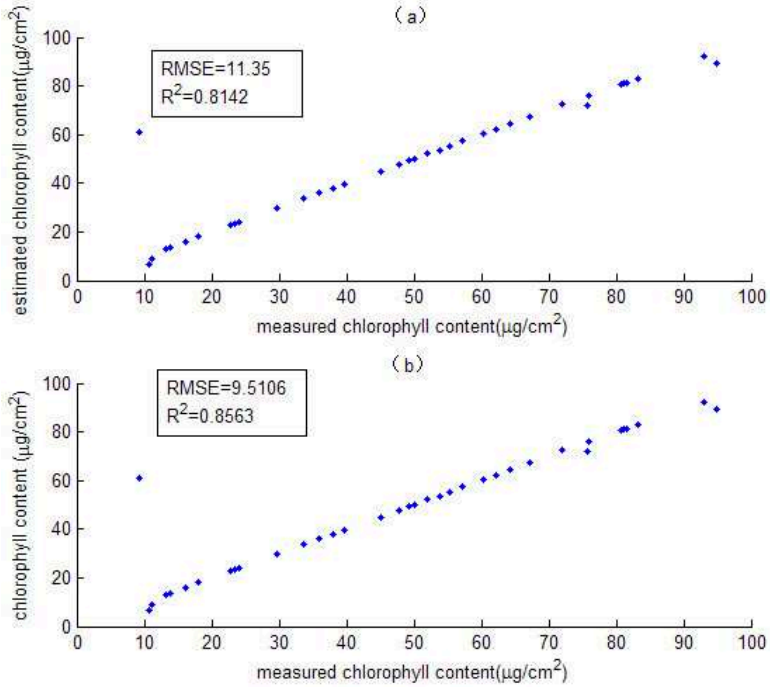

Fig. 1 Comparison of measured and estimated chlorophyll contents of rice.

The model was validated before it can be used to estimate rice chlorophyll content. Therefore, we compared the rice chlorophyll content with the measured rice chlorophyll content obtained from field tests (Fi.1). Fig.1 (a) is the comparison of the estimated chlorophyll content in rice on original

spectral data sets with the measured chlorophyll content of rice, Fig.1 (b) is the comparison of the estimated chlorophyll content in rice on the first derivative spectra data sets with the measured chlorophyll content of rice. On the original spectral data set, the coefficient of determination is 0.8142, the RMSE is 11.3510. On the first derivative spectra data set, the estimation model to obtain a coefficient of determination of 0.8563, and the RMSE is 9.5106. This indicates that the estimation model of chlorophyll content in rice based on support vector machine achieved a better accuracy on the first-order differential transformation, which is beneficial for the improving the precision of estimation model for chlorophyll content in rice.

4. Conclusion

This study established a chlorophyll content estimation model of rice using PROSPECT and support vector machine, and the parameters of support vector machine were using optimized using a grid search method. The Estimation model can be used as an effective tool for rapid tool for estimating chlorophyll content of rice, and can be applied to precision agriculture management. Future research will apply estimation model for estimating chlorophyll content in rice to large areas of sewage irrigation paddy field.

Keywords: Parallel and distributed computing; Expand-vector; Collaborative filtering; Recommend mechanism; MapReduce

Abstract. The recommendation system based on collaborative filtering is one of the most popular recommendation mechanisms. However, with the continuous expansion of the system, several problems that traditional collaborative filtering recommendation algorithm (CF) faced such as cold startup, accuracy, and scalability are worsen. In order to address these issues, a distributed collaborative filtering recommendation model based on expand-vector (CF-EV) is proposed. Firstly, the eigenvector is expanded reasonably to get the expand-vector based on the expand-vector model, a new extension measure created in this paper. Then, the nearest neighbor user is found and a more accurate recommendation to the target user is given based on the calculation results. In addition, the further optimization makes it applied to the parallel computing framework successfully. Using the MovieLens dataset, the performance of CF-EV is compared with CF from both sides of recommendation precision and the speedup ratio. Through experimental results, CF-EV overcomes the problem of cold startup. Moreover, the accuracy and recall ratio has been doubled. With the increasing numbers of the computing nodes, the distributed implementation has linear speedup.

Introduction

The amount of information is increasing far more quickly than our ability to process it. Thus, it is significant to utilize the technologies that can help us to find which information is the most valuable. One of the most promising technologies like this is collaborative filtering [1] which was proposed by Goldberg. With the development of e-commerce, its application area is becoming more and more abroad, such as the recommendation of the books in Amazon [2].Although the traditional collaborative filtering recommendation algorithm (CF) has achieved huge success in information filtering, it has three drawbacks: cold startup, sparsity and scalability. To solve these problems, many optimization methods are proposed. Breese and Hecherman[3] proposed a method which assigns default values to the unrated items. In Zhang et al. [4], based on the cloud model, a novel similarity measuring method named the likeness comparing method based on cloud model (LICM) was presented. It could overcome the drawback of attributes' strictly matching. Apache offered open source library named Mahout [5], which could make CF deployed to the Hadoop successfully.

In this paper, a new model is introduced to address three key issues. The innovations are embodied in the following aspects: An expand-vector model is presented to expand the object's eigenvector; A distributed collaborative filtering recommendation model based on expand-vector (CF-EV) is proposed, in which all the calculation is based on expand-vector; To CF-EV, whose distributed implementation is completed by further optimization on it; On the MovieLens data sets, the contrast tests of CF-EV and CF are made.

Related Works and Backgrounds

In this section, we review the background of CF and introduce its recommendation process.

As the main recommendation technology, the basic assumption of CF is that if user X and user Y rate n items similarly, they tend to rate on other items similarly. In general, there are three types of CF,

which are CF based on item, CF based on user and CF based on model. In the process of CF, three parts are included: fetching data, searching nearest neighbor and making recommendation. The specific details will be represented in the next section.

Distributed Collaborative Filtering Recommendation Model Based on Expand-vector

In this section, the specific process of CF-EV is as below:

Expand-vector Model. In a typical CF scenario, there exists two sets, I and J. $vector_j$ represents the eigenvector of element j: $vector_j=(p_{(1,j)}, p_{(2,j)}, \ldots, p_{(m,j)})$, $j\in J$, $1\le m\le M$. M means the total number of elements in the set I. $p_{(i,j)}$ represents the preference of element i to element j , $i\in I$. Expand the eigenvector, defining its expand-vector in forms of: $evector_j=(p_{(1,j)}, p_{(2,j)}, \ldots, p_{(m,j)}, a_{(j,1)}, a_{(j,2)}, \ldots, a_{(j,q)})$, $a_{(j,k)}$ means the k^{th} attribute's value of j, $1\le k\le Q$. Q stands for the total number of j's attributes.

Specific Application. The expand-vector model could be applied to any one of the recommendation algorithms which involves the eigenvector. Now, the model is applied to CF based on user:

Fetching Data. CF uses a ratings matrix, B, to represent the entire $m\times n$ user-item data, line m means the m^{th} user, column n represents the n^{th} item, each entry pij represents the rating of the target item j by user i. In general , $0\le pij\le 5$. Formula (1) shows the ratings matrix:

$$\boldsymbol{B}_{m\times n}=\begin{bmatrix} p_{11} & \cdots & p_{1n} \\ p_{21} & \cdots & p_{2n} \\ \vdots & & \vdots \\ p_{m1} & \cdots & p_{mn} \end{bmatrix} \tag{1}$$

Get Expand-vector. The item's expand-vector can be represented as $eivector_j=(p_{(1,j)}, p_{(2,j)}, \ldots, p_{(m,j)}, ai_{(j,1)}, ai_{(j,2)}, \ldots, ai_{(j,q)})$, $1\le j\le N$. N is the total number of the item. $ai_{(j,k)}$ means the k^{th} attribute's value of item j,$1\le k\le Q$.Q represents the total number of item's attributes. Analogously, the user's expand-vector can be represented as $euvector_i=(p_{(i,1)}, p_{(i,2)}, \ldots, p_{(i,n)}, au_{(i,1)}, au_{(i,2)}, \ldots, au_{(i,r)})$. $au_{(i,k)}$ means the k^{th} attribute's value of user i. More specifically, the categories of *item*'s attributes could include attributes like category and price. The categories of *user*'s attributes can include age and profession. Then, classify attributes according to attributes' value and convert the categorized results to digital format. Finally, the eigenvectors will be expanded reasonably, getting the expand-vectors.

Search Nearest Neighborhood. Here, all the calculation is based on expand-vectors. Take, for example, the similarity calculation of item j and item j':

1 Pearson correlation-based similarity

$$sim'_{(j,j')}=\frac{(m+q)(\sum p_{ij}p_{ij'}+\sum ai_{jk}ai_{j'k})-(\sum p_{ij}+\sum ai_{jk})(\sum p_{ij'}+\sum ai_{j'k})}{\sqrt{(m+q)(\sum p_{ij}^2+\sum ai_{jk}^2)-(\sum p_{ij}+\sum ai_{jk})^2}\sqrt{(m+q)(\sum p_{ij'}^2+\sum ai_{j'k}^2)-(\sum p_{ij'}+\sum ai_{j'k})^2}} \tag{2}$$

As is shown in formula (2),the Pearson correlation is a number between –1 and 1 that measures the tendency of two series of numbers, paired up one-to-one, to move together.

1 Euclidean distance-based similarity:

$$sim'_{(j,j')}=\frac{1}{1+\sqrt{\sum(p_{ij}-p_{ij'})^2+\sum(ai_{jk}-ai_{j'k})^2}} \tag{3}$$

The Euclidean distance, which we've seen in formula (3), is the most intuitive of all distance measures .This implementation is based on the distance between objects.

1 Tanimoto Coefficient-based similarity:

$$sim'_{(j,j')}=\frac{\left|U_j\cap U_{j'}\right|+\left|A_j\cap A_{j'}\right|}{\left|U_j\cup U_{j'}\right|+\left|A_j\cup A_{j'}\right|}. \tag{4}$$

Tanimoto Coefficient-based similarity is the ratio of the size of the intersection to the size of the union of users' preferred items. In formula (4), U_j means the set of users which have given the preference to item j. A_j means the set of j's attribute types. Analogously, the users' similarity calculation can be performed. After finishing all these related calculations, we can gain the user's similarity vector and items' similarity matrix. Besides, user's nearest neighbor can be received.

Make Recommendations.

$$R'_{(v,j')} = \frac{1}{|I_u|}\sum_{j\in I_u} sim'_{(j,j')}\, p_{(u,j)} \tag{5}$$

As is shown in formula (5), $R_{(v,j')}$ is used to estimate the preference value that user v may give to item j'. It is estimated on the basis of nearest neighborhoods' preference. Specifically, I_u represents the set of the items which user u has given the preference. Then, sort the $R'_{(v,j')}$ in descending order and choose the top W items to recommend to the target user, the value of W can be man-made in advance. At this point, the best recommendation (the most similar to item j) can be chosen.

Distributed Implementation of CF-EV

As the recommendation process of CF-EV is similar to the thought of Map-Reduce. So, the further optimization on CF-EV makes it applicable on the MapReduce[6] and Hadoop[7] successfully.

Transform File Format and Deploy the Input File. First, add a new file named users.txt, with its content concerning about those target users who will be given recommendation. Then, deploy the user preferences file (the Input File) on the HDFS [8] based on users.txt.

Generate User Preference Vector. The input file are treated as (*Long,String*) pairs by the framework, where the long key is a position in the file and the string value is the line of the text file. The framework collects all item*Id*s that were mapped to each user*Id* together. A reduce function constructors a vector from all item*Id*s for the user, and outputs the user*Id* mapped to the user's preference vector (this vector is named as "user preference vector").

Get Item Co-occurrence Matrix. Do Map and Reduce operation in accordance with the co-occurrence matrix method and user preference vector to get the item's co-occurrence matrix.

Get the User Expected Preference Matrix. Do parallel matrix multiplication operation of MapReduce on the user preference matrix and the item co-occurrence matrix to obtain the user expected preference matrix. The corresponding expected preference matrix is in forms of "userId_i : itemId_1, *expected preference*; … ; itemId_n , *expected preference*". The expected preference will be saved into the file in descending order. The generated file is placed on the HDFS server steadily.

Make Recommendations. Select the top-N items and recommend to the target user, then the recommendation is finished.

Experimentals and Results

In this section, we evaluate the CF-EV in comparison with CF.

Datasets. The three data sets of MovieLens (http://www.movielens.umn.edu) are used in our experiments, including ML-100K, ML-1M, and ML-10 M. Each data set is divided into two parts: 20% of the users are selected to be testing model, and the remaining as training model.

The Comparison of CF Based on Different Similarity Computation Methods. In this section, Precision and Recall ratio are introduced from the point view of information retrieval. The test is done on single machine, and ML-100K is used .The more detailed results are shown in table 1:

Table 1 Recommendation Results By Adopting Different Similarity Calculation Methods

Similarity Metrics	Accuracy	
	Precision	Recall
PearsonCorrelation	0.005 661 538	0.007 937 350
EuclideanDistance	0.001 169 231	0.001 514 680
TanimotoCoefficien	0.067 015 385	0.100 565 023

Table 2 Recommendation Results of CF-EV

Similarity Metrics	Accuracy	
	Precision	Recall
animotoCoefficien	0.124 984 615	0.187 860 704

In table 1, we can see that the precision and recall ratio of Tanimoto Coefficien has acquired qualitative leaps by contrast with other methods. So, the following experiment is based on this similarity calculation method which can provide the comparison of the recommendation algorithm.

The Comparison of CF-EV and CF. The experimental configuration and dataset is the same as the experiment mentioned above. The recommendation result is shown in table 2. The application of CF-EV promotes the recommendation precision and recall ratio increased by nearly 100%.

The Experiment about Cold Startup. To the problem about cold startup, we choose some items in ML-100K randomly, and the total number is 10, 20, 30, 40 and 50 respectively, removing the items' preference. Then CF-EV is used to predict the rating and the precision is shown in table 3:

Table 3 Recommendation Precision of the New Item

Algorithm	Precision				
	10	20	30	40	50
CF-EV	0.8999	0.9010	0.9188	0.8573	0.9076

Table 4 Runtime of Tasks on Single Machine (s)

Single machine	Run Time		
	100K	1M	10M
1	1190.8	1338000.3	11593004.7

Table 5 Runtime of Tasks on HOD Cluster (s)

Node Number	Run Time		
	100K	1M	10M
1	1 018	1 029	4 608
2	888	894	2 919
3	837	839	2 194

Table 6 Speedup of Tasks

Node Number	Speedup		
	100K	1M	10M
1	1	1	1
2	1.146 396	1.151 007	1.578 623
3	1.216 249	1.226 460	2.100 273

As is shown in table 3, the application of CF-EV makes the problem of cold startup resolved.

The Efficiency Evaluation of CF-EV's Distributed Implementation. The tests about this section are done on single machine and a small HOD (Hadoop on Demand) cluster respectively. The machine is constituted as follows: Dell Power Edge SC1430, Intel Xeon 5110 (1.6 GHz), Dual-core Processor, 4 GB of Physical Memory. The cluster is composed by 3 machines which are served as pbs_server, namenod and datanode respectively. All nodes which have the same configuration are installed the executable program of Hadoop distributions. More detailed results are shown in table 4~6.

Table 4~6 indicates that, as to the same data set, the run time of a single node has been reduced greatly compared with single machine, which reflects the MapReduce's advantages of data processing. Moreover, concerning the HOD cluster, with the increasing numbers of the computing nodes, a higher linear speedup is achieved. Besides, the optimal linear speedup can reach 1.5.

Conclusions

The paper firstly analyzes the disadvantages of the existed similarity measures and then a distributed collaborative filtering recommendation model based on expand-vector is proposed. Several experiments are performed on data sets and the results reveal the efficiency and accuracy of CF-EV. In the future, how to make the recommendation algorithm achieve a better combination with MapReduce? It will be the next research direction.

Keywords: cloud computing; resource scheduling; ant colony algorithm; particle swarm optimization algorithm

Abstract. This paper introduces PSO algorithm into ant colony optimization algorithm so that an improved ant colony optimization algorithm named ACA-PSO is proposed. The ACA-PSO algorithm can get more effective optimal solutions by using PSO algorithm to do crossover operation and mutation operation so as to avoid trapping in local optimum. Finally, the simulation experiment reflects that the ACA-PSO algorithm speeds the convergence up which is more suitable for resource scheduling in cloud computing.

Introduction

Cloud computing is a topic of hot debate in many fields such as computer science, business and so on. Allocation of computing resources is one of the most important component of cloud computing because its efficiency directly affects the performance of the whole cloud computing system. At the present stage, many scholars have introduced the ant colony algorithm (ACA) into the cloud computing system. The ACO overcomes the shortcomings of huge size of the node and lower allocation of resources for a single node, ensuring user’ s tasks can be completed on time. But the ACA has its disadvantages which include it is easy to fall into local optimal solutions, making inefficient resource scheduling [1]. Therefore, it is necessary to improve the ACA algorithm based on particle swarm optimization algorithm (PSO) to improve the efficiency of resource scheduling in cloud computing system.

Interpretation of Related Problems

Cloud Computing and Its MapReduce Level Scheduling. Cloud computing which is in grid computing based on a new calculation model, is the core technology of the next generation network computing platforms. It builds virtual super computer which provides data storage, analysis and scientific computing services through the distributed computing model and the resource pool technology [2]. Cloud computing is also a kind of distributed computing. By using of the virtualization technology, the idle computer resources can be combined into a huge resource pool which is constituted as a super computing capacity of the computer. Calculation nodes can be put into a dynamic system, which has fully realized the dynamic autonomy function, according to the need for computing resources, storage space and various software service from each application [3].

The key technology of MapReduce in Cloud computing is step-by-step type processing technology. MapReduce class scheduling is the core of the cloud computing resources scheduling which is the realization of the logical step calculation realized and all the task scheduling will be realized through this model. In MapReduce programming mode, concurrent processing, fault tolerant processing and load balance problems are abstracted as a function library. Through the MapReduce interface, user can put the large-scale computing to be automatic concurrent and distribution implementation [4]. MapReduce programming model calculation of the implementation process can be abstracted as three role: master, worker and user. Master is a central controller system, responsible for task allocation, load balance and fault tolerant processing. Worker is responsible for receiving

task from Master, carries on the data processing and calculation, as well as responsible for data transmission communication. User is a client who inputs the task to realize the Map and Reduce function and controls the whole calculation processes.

Ant Colony Algorithm. The ant colony algorithm is a probabilistic technique for solving computational problems which can be reduced to finding optimal paths through graphs.

The first version of ant colony algorithm, which is initially proposed by Marco Dorigo in 1992 in his PhD thesis [5], was aiming to search for an optimal path in a graph, based on the behavior of ants seeking a path between their nest and a source of food. The original idea has since diversified to solve a wider class of numerical problems, and as a result, several problems have emerged, drawing on various aspects of the behavior of ants.

In the natural world, ants initially wander randomly, and upon finding food return to their nest while laying down pheromone trails. If other ants find such a path, they are likely not to keep traveling at random, but to instead follow the trail, returning and reinforcing it if they eventually find food. When the ant k moves to the next node j from node i, the node j can be decided with the probability $P_{ij}^{k}(t)$ which can be calculated by formula (1):

$$P_{ij}^{k}(t)=\begin{cases}\dfrac{\tau_{ij}^{\alpha}(t)\eta_{ij}^{\beta}(t)}{\sum_{s\in A_k}\tau_{is}^{\alpha}(t)\eta_{is}^{\beta}(t)} & j\in A_k\\ 0 & otherwise\end{cases} \tag{1}$$

Where $\tau_{ij}(t)$ denotes the pheromone density, A_k is the set of optional nodes adjacent to node i. α is the heuristic factor of pheromone. β is the heuristic factor of expectation. $\eta_{ij}(t)$ is the distance function which denotes the heuristic information of path. $\eta_{ij}(t)$ can be described as formula (2):

$$\eta_{ij}(t)=\frac{1}{d_{ij}} \tag{2}$$

Where d_{ij} denotes the distance from node i to node j.

Over time, however, the pheromone trail starts to evaporate, thus reducing its attractive strength. The more time it takes for an ant to travel down the path and back again, the more time the pheromones have to evaporate. A short path, by comparison, gets marched over more frequently, and thus the pheromone density becomes higher on shorter paths than longer ones. Pheromone evaporation also has the advantage of avoiding the convergence to a locally optimal solution. If there were no evaporation at all, the paths chosen by the first ants would tend to be excessively attractive to the following ones. In that case, the exploration of the solution space would be constrained.

Local pheromone updating strategy is regarded as follows:

$$\tau_{ij}(t+n)=(1-\rho)\cdot\tau_{ij}(t)+\Delta\tau_{it}(t) \tag{3}$$

Where ρ is the evaporation rate of pheromone. $\Delta\tau_{it}(t)$ denotes the increment of pheromone on path (i , j) during once iteration. $\Delta\tau_{it}(t)$ can be gain by formula (4) as follows:

$$\Delta\tau_{it}(t)=\begin{cases}Q/L_k & (i,j)\\ 0 & otherwise\end{cases} \tag{4}$$

Where Q is the pheromone density and L_k denotes the total length of the route ant k passed by.

PSO Algorithm. Initialize a group of random particles in a space, the particle position represents possible solution, each particle advances to a certain speed, particle swarm gradually approaches to the optimal location after repeated advances which are also called iteration, thus the optimal solution will be got [6]. In each iteration, the particles update themselves according to two extreme values: one is the optimal solution finding by a single particle, namely the individual extremum; the other is the optimal solution finding by whole particle swarm, that is, namely the global extremum. Particles update their velocity and position according to the two extreme values above and the following two formulas.

$$V=\alpha\times v+c_1\times rand()\times(pBest-X)+c_2\times rand()\times(qBest-X) \tag{5}$$

$$X = X + V \tag{6}$$

Where $V = [v_1, v_2, \cdots, v_m]$ is the velocity of the particle, $X = [x_1, x_2, \cdots, x_m]$ is the current position of the particle, d is the dimension of solution space. pBest is the individual extremum, qBest is the global extremum, rand() is random number between 0 and 1. Both c_1 and c_2 are called learning factors which are used to adjust the particle update step, α is a weighted factor.

The particle swarm gradually closes to the optimal solution location through continuous learning and updating. The qBest which is the global optimal solution will be got by using the algorithm.

Improved Ant Colony Algorithm based on PSO and Its Application on Resource Scheduling

The main idea of improved ant colony algorithm based on PSO (ACA-PSO) proposed in this paper is that let the ants have the characteristics of the "particles". Firstly, the ants are in accordance with the ant colony algorithm to complete a traverse, then they adjust solutions according to the local optimal solutions and global optimal solutions.

Adjustment is described as: the current positions of resource scheduling are behalf of the basic path nodes set. $\alpha \times v$ can be regarded as the mutation operation of genetic algorithm, and $c_1 \times (pBest - X) + c_2 \times (qBest - X)$ can be regarded as the crossover operation of genetic algorithm, which lets the current solution do crossover operator with the individual extremum and the global extremum so as to produce a new location.

The crossover strategy in improved algorithm is: select a cross region randomly in the second string, old_2 is added to the old_1 corresponding position, delete the nodes in old_2 appeared in the old_2 cross- region. Variation strategy is: select the node of j_1 visits from the nodes of 1-n visit, exchange the j_1 node and the $j_1 + 1$ node in nodes set N_0, and the rest keep unchanged. At this time, the path set node is N_1.

A node may have to run multiple tasks at the same time in cloud computing. But it will improve performance of entire cloud if tasks are assigned to the most efficient node. Therefore, a task expected execution time model is established to predict execution time of the new tasks on the node, the formula is as follows:

$$ET_j^{n_m}(J_m(t_2)) = \frac{n_m}{n_v} \cdot (\rho ET_j^{n_v}(J_v(t_0)) + (1-\rho) RT_j^{n_v}(J_v(t_1))) \tag{7}$$

Where $ET_j^{n_m}(J_m(t_2))$ represents the new task J_m estimating the expected execution time on the j node at time t_2. n_m denotes the load of node j at time t_2. $ET_j^{n_v}(J_v(t_0))$ represents the expected execution time of previous completed task J_v at time t_0. $RT_j^{n_v}(J_v(t_1))$ denotes the actual execution time of previous task completed at time t_1. n_v denotes the load of previous task.

Simulation Experiment

The simulation experiments are carried out in the MATLAB by using ACA-PSO and basic ant colony algorithm (ACA) separately. The simulation data include: number of ants m=10, maximum number of iterations is 500, $\alpha = 1.5$, $\beta = 2$, $\rho = 0.9$. The experimental results are shown in Fig.1.

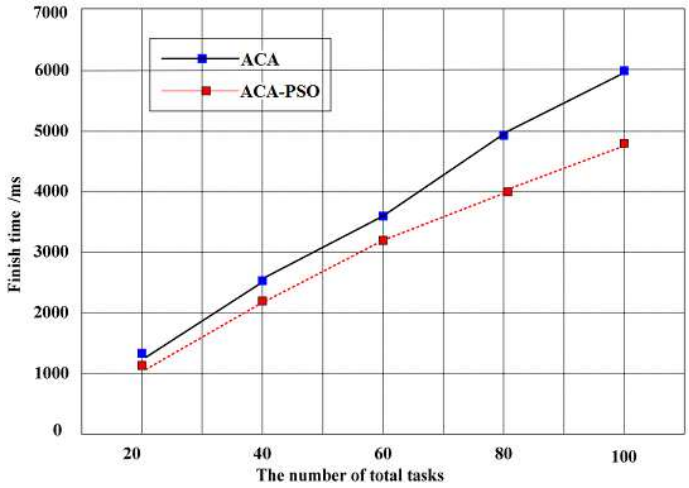

Fig. 1 Comparison of the Two Scheduling Algorithms

The results shown in Fig.1 reflect that the execution time of ACA-PSO is shorter than ACA. So ACA-PSO has higher efficiency for resource scheduling in cloud computing.

Conclusion

In this paper an improved ant colony algorithm based on PSO named ACA-PSO is proposed. ACA-PSO overcomes the disadvantage that the ant algorithm is easy to fall into local optimal solution in the cloud computing resource scheduling. Experiment results shows that ACA-PSO can accelerate the convergence speed, avoid trapping into local optimum solution so as to be more suitable for resource scheduling in cloud computing.

[a]yanghai_sdjtu@163.com

Keywords: traveling salesman problem; ant colony algorithm; chaos optimization; simulation experiment

Abstract. In this paper an improved chaos ant colony algorithm based on return optimization strategy, elite strategy and intersection removal strategy is proposed. The improved algorithm uses orthogonal method to cluster the target points, then adopt chaos technology to optimize initial solution of the ant colony to improve individual quality and chaos perturbation is utilized to avoid the search being trapped into local optimum solutions. The simulation results show that the improved algorithm has higher efficiency in finding optimal path and it is a novel method to solve traveling salesmen problem.

Introduction

The traveling salesman problem (TSP) asks the following question: Given a list of cities and the distances between each pair of cities, what is the shortest possible route that visits each city exactly once and returns to the origin city? It is an NP-hard problem in combinatorial optimization, important in operations research and theoretical computer science.

In the theory of computational complexity, the decision version of the TSP belongs to the class of NP-complete problems. Thus, it is possible that the worst-case running time for any algorithm for the TSP increases superpolynomially with the number of cities [1].

The problem was first formulated in 1930 and is one of the most intensively studied problems in optimization. It is used as a benchmark for many optimization methods. Even though the problem is computationally difficult, a large number of heuristics and exact methods are known, so that some instances with tens of thousands of cities can be solved completely and even problems with millions of cities can be approximated within a small fraction of 1%.

The TSP has several applications even in its purest formulation, such as planning, logistics, and the manufacture of microchips. Slightly modified, it appears as a sub-problem in many areas, such as DNA sequencing. In these applications, the concept city represents, for example, customers, soldering points, or DNA fragments, and the concept distance represents traveling times or cost, or a similarity measure between DNA fragments. In many applications, additional constraints such as limited resources or time windows may be imposed.

Ant Colony Optimization Algorithm (ACO) is a population-based optimization approach which has been successfully applied to solve different combinatorial optimization problems such as TSP, QAP, job-shop scheduling, etc. One of main ideas of ant colony algorithms is the indirect communication of a colony of agents, called artificial ants, based on pheromone trails. The artificial pheromone trails are a kind of distributed numeric information which is modified by the ants to reflect their experience while solving a particular problem.

Ant Colony Algorithm and Chaos Selection Strategy

Ant Colony Algorithm. The ant colony algorithm is initially proposed by Marco Dorigo in 1992 in his PhD thesis [2], was aiming to search for an optimal path in a graph based on the behavior of ants seeking a path between their nest and a source of food. The original idea has since diversified to solve

a wider class of numerical problems, and as a result, several problems have emerged, drawing on various aspects of the behavior of ants.

When ant colony algorithm starts, every ant wanders randomly to find foods returning to their nest while laying down pheromone on the path it passed. If other ants find such a path, they are likely not to keep traveling at random, but instead of following the path, returning and reinforcing the density of pheromone of the path if they eventually find food. When the ant k moves to the next node j from node i, the node j can be decided with the probability $P_{ij}^{k}(t)$ which can be calculated by formula (1):

$$P_{ij}^{k}(t)=\begin{cases}\dfrac{\tau_{ij}^{\alpha}(t)\eta_{ij}^{\beta}(t)}{\sum_{s\in A_k}\tau_{is}^{\alpha}(t)\eta_{is}^{\beta}(t)} & j\in A_k\\ 0 & otherwise\end{cases} \tag{1}$$

Where $\tau_{ij}(t)$ denotes the pheromone density, A_k is the set of optional nodes adjacent to node i. α is the heuristic factor of pheromone. β is the heuristic factor of expectation. $\eta_{ij}(t)$ is the distance function which denotes the heuristic information of path. $\eta_{ij}(t)$ is described as formula (2):

$$\eta_{ij}(t)=\frac{1}{d_{ij}} \tag{2}$$

Where d_{ij} denotes the distance from node i to node j.

Over time, however, the pheromone trail starts to evaporate, thus reducing its attractive strength. The more time it takes for an ant to travel down the path and back again, the more time the pheromones have to evaporate. A short path, by comparison, gets marched over more frequently, and thus the pheromone density becomes higher on shorter paths than longer ones. Pheromone evaporation also has the advantage of avoiding the convergence to a locally optimal solution [3]. If there were no evaporation at all, the paths chosen by the first ants would tend to be excessively attractive to the following ones. In that case, the exploration of the solution space would be constrained.

Local pheromone updating strategy is regarded as follows:

$$\tau_{ij}(t+n)=(1-\rho)\cdot\tau_{ij}(t)+\Delta\tau_{it}(t) \tag{3}$$

Where ρ is the evaporation rate of pheromone. $\Delta\tau_{it}(t)$ denotes the increment of pheromone on path (i , j) during once iteration. $\Delta\tau_{it}(t)$ can be gain by formula (4) as follows:

$$\Delta\tau_{it}(t)=\begin{cases}Q/L_k & (i,j)\\ 0 & otherwise\end{cases} \tag{4}$$

Where Q is the pheromone density and L_k denotes the total length of the route ant k passed by.

Chaos Selection Strategy. When ant colony algorithm initializes, the strength of pheromones on every road section is equal so that the possibility of every road section is equal. It is difficult for ant colony to find an optimization path; besides, the convergence speed of algorithm is slow. So using chaos operator is necessary because it can increase the searching efficiency by the random and ergodic of chaos.

Take the logistics mapping for example [4], iterative formula is as follows:

$$z_{i+1}=\mu\cdot z_i\cdot(1-z_i),\quad i=0,1,2,\cdots,\quad \mu\in(2,4] \tag{5}$$

Where, μ is the control parameter, with the domain between (2, 4]. When μ= 4, $0\le z_0\le 1$, logistic function is the full mapping in (0, 1), which is at a totally chaos status. A chaos sequence will be created by the iteration [5], and then be converted to a chaos ergodic parameter when solving optimization problems in space. After introducing chaos perturbation, the new status transition strategy becomes:

$$p_{ij}^{k}(t)=\begin{cases}\dfrac{[\tau_{ij}^{s}(t)]^{\alpha}\cdot(r_{ij}^{s})^{\beta}\cdot(\delta_{ij})^{\theta}(1+Z_{ij})^{\gamma}}{\sum_{j\in allowed_k}[\tau_{ij}^{s}(t)]^{\alpha}\cdot(r_{ij}^{s})^{\beta}\cdot(\delta_{ij})^{\theta}(1+Z_{ij})^{\gamma}}, & j\in allowed_w\\ 0, & otherwise\end{cases} \tag{6}$$

Where,

$$\delta_{ij} = \begin{cases} \dfrac{\max[0, LT_{ij} - \max(ET_j, ET_{ij})]}{LT_j - ET_j}, & if \quad LT_j \geq LT_{ij} \\ \dfrac{\max[0, LT_j - \max(ET_j, LT_{ij})]}{LT_j - ET_j}, & else \end{cases} \tag{7}$$

$$ET_{ij} = ET_i + T_i + t_{ij} \tag{8}$$

δ_{ij} is the heuristic information of time windows which reflects the urgency of time.

Improved Chaos Ant Colony Algorithm (ICACA)

In chaos ant colony algorithm mentioned above, the chaos initialization accelerates the convergence velocity and to a certain extent, the chaos perturbation overcomes the disadvantage that the ant colony algorithm is easy to trap into the local optimum solutions. However, the optimal solution by using the chaos ant colony algorithm exists intersection so that the quality of optimal solution should be improved further on.

In order to improve the quality of the optimal solutions of ant colony algorithm, the local optimization technologies including return optimization strategy, elite strategy and intersection removal strategy are introduced into the chaos ant colony algorithm.

Return Optimization Strategy. The transition probability equation of basic ant colony algorithm is only related to the distance between the current node and candidate nodes available, but not considering the distance between the last node and the starting node. Therefore, the quality of optimal solution is significantly affected by the span between the last node and the starting node. So the return optimization strategy is very important for improving the quality of optimal solution. The selection of path omitting the distance between the last node and the starting node is shown in Fig.1. The selection of path using return optimization strategy is shown in Fig.2.

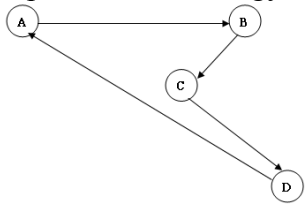

Fig.1 Basic Selection of Path

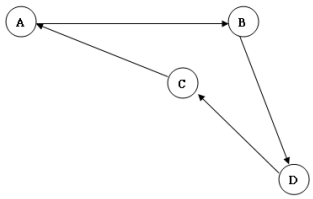

Fig.2 Return Optimization Strategy

The key of return optimization strategy is the factor $\mu_{ij} = d_{i0} + d_{0j} - d_{ij}$ which not only considers the distance between current node and the next candidate nodes, but also considers the distance between each candidate node and the starting node. Therefore, the quality of optimal solution is significantly improved. The new transition probability equation becomes:

$$p_{ij}^k(t) = \begin{cases} \dfrac{[\tau_{ij}^s(t)]^\alpha \cdot (\eta_{ij}^s)^\beta \cdot (\mu_{ij})^\theta (1+Z_{ij})^\gamma}{\sum_{s \in allowed_k} [\tau_{is}^s(t)]^\alpha \cdot (\eta_{is}^s)^\beta \cdot (\mu_{is})^\theta (1+Z_{ij})^\gamma}, j \in allowed_w \\ 0, \quad otherwise \end{cases} \tag{9}$$

Elite Strategy with Threshold. When once iteration of chaos ant colony algorithm is finished, if the total length of one found path is less than the threshold, the pheromone of this path will be increased according to the formula as follows:

$$\tau_{ij}(t+1) = (1-\rho) \cdot \tau_{ij}(t) + \sum_{l=1}^{L} \Delta \tau_{ij}^l \tag{10}$$

$$i = 1,...,N \qquad j = 1,...,K$$

Where ρ is the evaporation rate of pheromone.

Intersection Removal Strategy. Because the zone drawn by the optimal soluton must be a single connected subgraph, the performance of chaos ant colony algorithm will be improved by using the

intersection removal strategy. The intersection removal strategy can be described as two steps as follows:

Step1: For j=1 to n-2

Step2: For k=j+2 to n-1

If d(j, k)+d(j+1, k+1)<d(j, j+1)+d(k, k+1), it is known that there are intersection. Then execute the following operations: replace the old path (j, j+1), (k, k+1).

k=k+1, goto step2;

j=j+1, goto step1;

End

Simulation Experiment

The simulation experiments are carried out by using the improved chaos ant colony algorithm (ICACA) and basic chaos ant colony algorithm (BCACA) separately. The experimental city data are from standard testing library including oliver30, eil51, eil76 and ch130. The factors of chaos ant colony algorithm include: number of ants m=50, maximum number of iterations is 500, $\alpha = 2$, $\beta = 4$, $\theta = 1.5$, $\gamma = 1$, $\rho = 0.9$, $Q = 100$. The experimental results are shown in Table 1.

Table 1 Comparison of the Results of Two Chaos Ant Colony Algorithm

Algorithm	Oliver30	Eil51	Eil76	Ch130
ICACA	421.39	430.02	537.21	6123.67
BCACA	423.79	431.82	550.51	6169.26

The results reflect that the optimal solutions of ICACA are superior to those of BCACA. So ICACA has higher efficiency for finding the optimal solution in traveling salesman problem.

Conclusion

This paper proposes an improved chaos ant colony algorithm named ICACA which is based on return optimization strategy, elite strategy and intersection removal strategy. The ICACA algorithm uses chaos technology to optimize initial solution of the ant colony to improve individual quality and chaos perturbation is utilized to avoid the search being trapped into local optimum solutions. The simulation results show that ICACA has higher efficiency in finding optimal path and it is more suitable for traveling salesmen problem.

An Improved Scheduling Algorithm for Cloud Storage

Pei Wang

Department of Computer Application & Engineer, Hebei Software Institute,Baoding ,China

stony067_w@163.com

Keywords: Cloud storage data; nodes schedule Priority

Abstract. In this paper, the authors briefly describe the development of cloud storage and give an improved cloud storage model. This paper proposes a scheduling algorithm based on Priority(SAP). According to the priority of data block ,the algorithm schedules on mastering the supply and demand of data block comprehensively and accurately, and solves the system's launch delay and the continuity of streaming media player.

Introduction

Cloud computing is a commercial computational model,which combines the IT technology and the Internet to achieve super computing and storage capacity.However,the difference between the cloud storage and the traditional storage is not just the storage space.Storage virtualization is a major feature of cloud storage, which is different from traditional storage.It proposed the concept of a storage device which is from physical to logical.It provides a simple,unified composite structure for enterprise storage resource consumption.Currently,the major high - performance distributed file systems which are used in cloud storage platform all use this concept such as GFS of Google, S3 of Amazon and“Blue Cloud”of IBM.This is the basis of an improved cloud storage model which is proposed in this paper.

With the development of cloud, the concept of“service”in traditional Service-Oriented Architecture (SOA) is extended from software application to generalized “cloud Service”with the inclusion of both software applications and hardware equipments with good interoperability, self-organization and scalability. The properties of cloud services have become more complex and most of them need higher computing ability to drive.

In such environment, when a composite project (which contains a set of tasks)is submitted, the console of conglomerate needs not only to aggregate suitable cloud services with different functionalities and generate service portfolio for user on-demand,but also choose available computing resources to support the running of cloud services. How to achieve high-quality and low cost Services Composition Optimal Selection (SCOS) and Optimal Allocation of Computing Resources(OACR) simultaneously are critical for efficient project execution, green resource sharing and flexible service management.

Analysis of the Current Research Situation

At present, there are lots of methods to study video data management, Such as: RAID, SAN, disk duplexing, partition mirror, single disk array, disk array, Fault-tolerant software hot backup, replication, cluster technology, CDN technology, P2P technology, cloud storage technology and so on.

RAID5 technology uses a block cross access to the data banding of distributed-check data, then writes to all disks in the parity. Data redundancy is provided by the parity information; data and parity information are placed in different disk among disk array. When a disk faults, the read performance will drop because the parity information needs to recover data; on the other hand, due to parity calculations, the use of block cross access to the data banding of distributed-check data is more effective than image-type.

Replication is at the expense of storage capacity to get the scalability of system. Due to increasing hardware storage capacity, the advantages of stripe exist no longer, Therefore, the video server cluster systems use replication technology to implement data distribution now .

By adding a new layer of network architecture to the existing Internet, CDN (Content Delivery Network) technology distributes center content to the nearest users and network "edge" node for the best service capacity; through the intelligent strategy, Which allows users to obtain the required contents, resolves Internet network congestion, and improves users' response time of the web access. With the (Decentralized)approach, P2P technology is such a new network computing technology that uses a large number of dynamic autonomy distribution resources to accomplish specific functional. P2P technology combines with individual users into a network whose bandwidth and information can be shared with.

Cloud Storage Systen Model

We use the general business machines as the underlying storage devices and Hadoop as a platform of cloud storage environment, managing the underlying business called HDFS ,It is shown in Figure1.We discuss the data management algorithms in the data node of cloud storage in this paper.

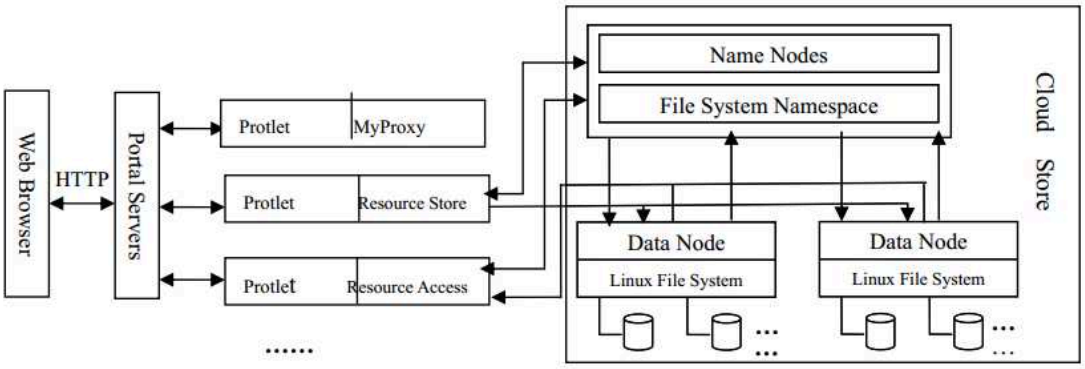

Figure 1 Implementation model of cloud storage

Scheduling Algorithm Based on Priority (SAP)

In streaming model, the existing data scheduling strategy includes the following: Rarest-First strategy (Rarest-First, RF). This strategy is conducive to speeding up the data block in the proliferation of network coverage and improving the overall throughput of the system and getting a better average playing continuity. But because of no taking into account the urgency degree of block elements, it results in a large start delay; Weighted Round-Robin (Weighted Round-Robin, WRR) strategy uses the size of the bandwidth, layer data block priority as the main basis for scheduling to get load balancing, but the chance of improving data is considered inadequately; Greedy strategy, known as the nearest deadline first (nearest deadline first) strategy, provides visually a good start late and playing continuity. But after testing and analysis, this strategy gets poor performance because Greedy strategy will likely lead to decline the shared probability of data blocks gradually and result in the performance reduce for overall system, eventually it makes each node of the playback not be achieved; Random strategy selects an ongoing request randomly from the partners node, this strategy's performances is not very stable, especially in the heterogeneous network environment. For the problems of scheduling algorithms and the cloud storage system, we propose a scheduling algorithm based on priority(SAP). According to the priority of data block, the algorithm schedules on mastering the supply and demand of data block comprehensively and accurately. The experimental results show that SAP algorithm has further improved in playing continuity and launch delay than the minimum priority scheduling algorithm.

Algorithm Description:

(1) According to descending order of scheduling priority of data block sequence is A1, A2, ..., Am;

(2)The corresponding sequence of data blocks has a collection of nodes are S1, S2, ..., Sm;

(3) Sending rate of all the neighbor nodes are R (1), R (2), ..., R (n);

(4) In the current scheduling cycle, the expected send wait time of each neighbor is Wait (1), Wait (2), ..., Wait (n), the initial values are 0.

Output Each data block has a sending node sender Ai

Algorithm: max get $\leftarrow \min(m, \tau \times I)$; / / Current scheduling cycle can receive the maximum number of data blocks

for i = 1 to get max do

$t_{\min} = \infty$ / / initialize for the first time Ai

for j = 1 to k do

$t_{deliver} = \frac{Lenght}{R_j^i}$ / / obtained Ai expected time from the Sj

if $t_{deliver}$ + Wait (S_j^i) < $t_{\min}$ and $t_{deliver}$ + Wait (S_j^i) <τ

$t_{\min} \leftarrow t_{deliver} + Wait(S_j^i)$ $\text{sender}_i \leftarrow S_j^i$;

end for j;

if $\text{sender}_i \neq$ null

Wait (sender_i) $\leftarrow t_{\min}$;

end for i;

Experiment and Result Analysis

We use NS2 as a simulator, and the output bandwidth of the user nodes is [200,600]Kb/s, access bandwidth is [400,1000] Kb/s, server output bandwidth is 100Mb/s. Streaming media file playback time is 30min in the data nodes of cloud store. Users join the network node shows Poisson distribution. Streaming media file playback speed is 400Kb/s. In order to compare the performance of SPA algorithm in the simulation experiment,Also implement the same strategy of the RF, Simulation results are Figure2 and Figure3 thought comparing.

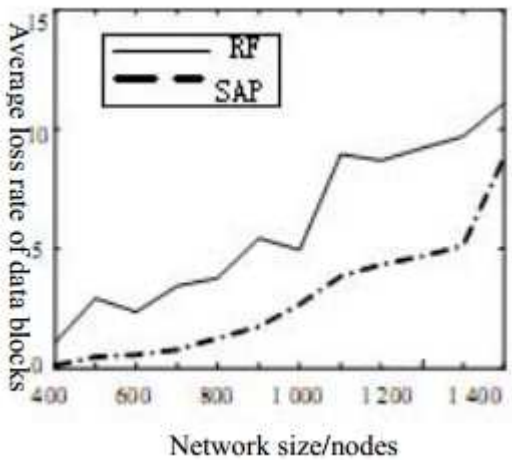

Figure2 Average loss rate of data blocks

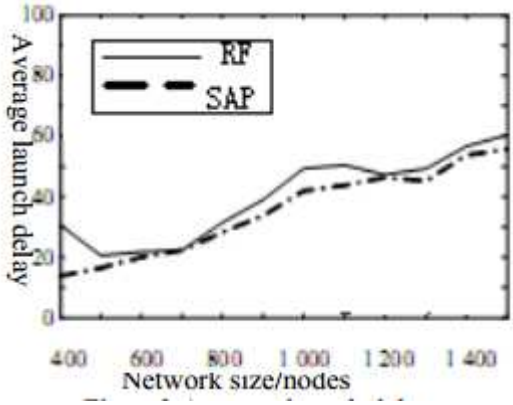

Figure3 Average launch delay

We can be seen indicators curve growth is slow and smooth from the above of the experimental, It is indicating that data of scarcity degrees and high urgent data blocks will be scheduling priority in the same bandwidth conditions, and can effectively reduce the loss rate, improve the system Continuous playback. System startup launch is correspondingly reduced.

Keywords: RC-π Model; Spatial Correlation; Process Variations

Abstract. To solve the crosstalk noise question in deep-submicron technologies, a new spatial correlation model based on the distributed RC-π model is proposed in this paper. Quiet aggressor net and tree branch reduction techniques are introduced to the distributed RC-π model, and a new spatial correlation model of both Gaussian and non-Gaussian process variations among segments is created. Experimental results show that our method maintains the efficiency of past approaches, and significantly improves on their accuracy.

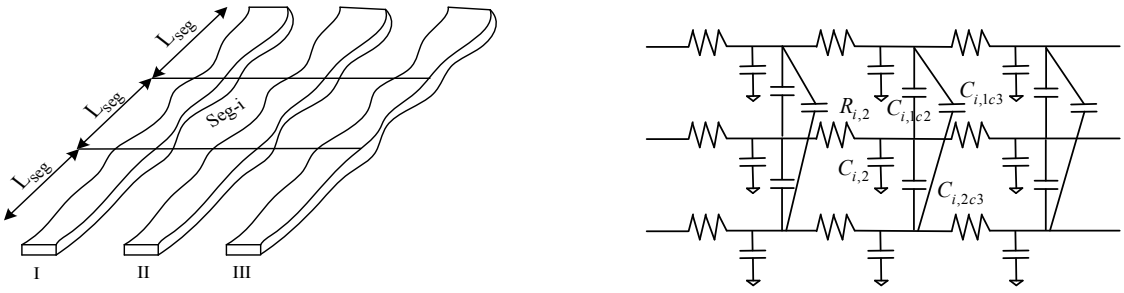
1. Introduction

The increase in package density as well as the clock frequency of the VLSI circuits has made interconnect parasitic effects become increasingly significant, and crosstalk noise is one of the most challenging problems in the design and verification of modern VLSI circuits. The statistical model of [1] uses a lumped RC model to explore crosstalk-induced pulse effect, where a single resistance is extracted to capture the effect of total self resistance of interconnect, regardless of its length. The case for self and coupling capacitances is similar. The statistical model proposed in [2] is more sophisticated and uses a circuit model with higher number of nodes; however, still a single capacitance is extracted to model the total coupling effect, which makes it inappropriate for long interconnect lines. The authors of [3] apply distributed RC-π model to study the statistics of crosstalk effect, but the complexity of model reduction becomes huge because of considering process variations.

In this paper, a new spatial correlation model based on the distributed RC-π model is proposed to solve on-chip crosstalk noise. The paper is organized as following: In section 2, quiet aggressor and tree reduction techniques in distributed RC-π model is presented to reduce the complexity of circuit model. In section 3, the grid-based model is used to generate the spatial correlation among each neighboring segments of reduced distributed RC-π model. Section 4 shows experimental results while section 6 concludes this paper.

2. Reduction of distributed RC- π model

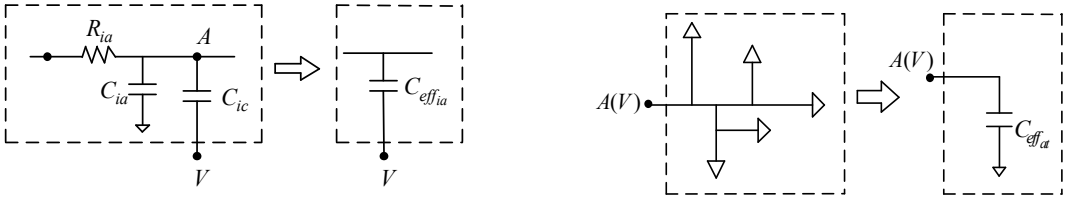
Consider three coupled interconnect lines in some metal layer, which lies in between two dielectric plates (cf. Fig. 1(a)). The three interconnect lines run in parallel and are capacitively coupled. A distributed RC-π model (cf. Fig. 1(b)) is used to accurately model the abovementioned interconnect line configuration. In this circuit, each RC-π stage represents an interconnect segment of a predefined length, L_{seg}, which is an important factor when considering spatial correlation among physical parameters as will be explained in section 4. The couplings between each two interconnect lines along segment *i* are captured by the coupling capacitances $C_{i,1c2}$, $C_{i,1c3}$, $C_{i,2c3}$, respectively. The self capacitance and resistance of line II in segment *i* are denoted by $C_{i,2}$ and $R_{i,2}$, respectively. Note that although lengths of all wire segments are identical, due to process variations, parameter values for each segment are different from those for other segments.



(a) (b)

Fig. 1 Distributed capacitive modeling of coupled interconnects

In general, a net has a tree structure instead of being a simple wire. Millions of interconnect lines in VLSI circuit limit the application of distributed RC-π model in real design. [4] presents the quiet aggressor and tree reduction techniques and used a 6 node template circuit for fast crosstalk estimation, however, 6 node template circuit is not suitable to the crosstalk noise analysis of interconnects in deep submicron process. In this section, we introduce quiet aggressor and tree reductions to distributed RC-π model and present a novel quiet aggressor and tree reduction techniques for distributed RC-π model as shown in Fig. 2. Fig. 2(a) shows the quiet aggressor reduction process to reduce aggressors non-switching and not switching simultaneously with victim V in segment i; Fig. 2(b) shows the tree branches reduction process of the victim or aggressor in distributed RC-π model. Effective capacitances $Ceff_{ia}$ and $Ceff_{at}$ can be easily derived by matching the lower order Taylor series expansion coefficients of the admittances at the coupling point and branching point, correspondingly.



(a) Quiet aggressor net reduction (b) Tree branches reduction

Fig. 2 Reduction process of distributed RC-π model

Therefore, using quiet aggressor net and tree reduction techniques the crosstalk noise estimation problem for a general RC tree structure circuit is transformed to a much simpler one of solving the reduced distributed RC-π circuit, which not only improves the accuracy and efficiency of crosstalk noise analysis but also makes our proposed approach be applicable to real design.

3. Spatial correlations

In our method, we assume statistical independence between Gaussian and non-Gaussian parameters. The spatial correlation among the variation of neighboring segments is quiet important in the crosstalk noise of the victim interconnect. For example most of the variation resulting from chemical-mechanical polishing of the inter-layer dielectric is based on systematic spatial effects and vanes within-die. In this paper, we employ grid-model to generate the exacter spatial correlations of process variables in segments of reduced distributed RC-π model. We partition the die into $g_{row} \times g_{col} = g$ grids, as shown in Fig. 3.

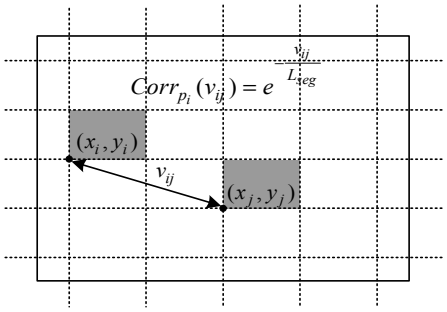


Fig. 3 The grid-model of spatial correlations

Since segments close to each other are more likely to have more similar characteristics than those placed far away, we assume perfect correlations among the segments in the same grid, high correlations among those in nearby grids and low or zero correlations in faraway grids. The correlation function $Corr(x_i, x_j, y_i, y_j)$ between any two points (x_i, y_i) and (x_j, y_j) in the grid depends only on the distance v_{ij} between them, as follows:

$$Corr(x_i, x_j, y_i, y_j) = Corr(\sqrt{(x_i - x_j)^2 + (y_i - y_j)^2}) = Corr(v_{ij})$$

It has been observed that the spatial correlation function $Corr(v_{ij})$ is a monotonically decreasing function of distance v_{ij}. However, not all monotonically decreasing functions qualify for the spatial correlation function. A necessary and sufficient condition for function $Corr(v_{ij})$ to be a valid spatial correlation function of a homogeneous and isotropic random field is that it can be represented in the form of [5]:

$$Corr(v_{ij}) = \int_0^\infty J_0(wv_{ij}) d(\phi(w)) \tag{1}$$

where $J_0(t)$ is the Bessel function of order zero and $\phi(w)$ is a real nondecreasing function on $[0, \infty]$ such that for some non-negative p:

$$\int_0^\infty \frac{d\phi(w)}{(1+w^2)^p} < \infty$$

In this paper, $\phi(w) = 1 - 1/\sqrt{1 + w^2 L_{seg}{}^2}$. By plugging it into Eq. (1), we obtain the corresponding correlation function as:

$$Corr(v_{ij}) = \exp(-v_{ij} / L_{seg})$$

where L_{seg} is a predefined segment length that regulates the decaying rate of the correlation function with respect to distance v_{ij}. The spatial correlation in this paper is an exponential decay function of distance, but our RD-SCNA algorithm doesn't limit to exponential function.

In addition, we assume that correlation exists only among the same type of parameters and there is no correlation between different types of parameters. For each type of parameter in reduced distributed RC-π model, a sparse correlation matrix M of size $g \times g$ represents the spatial correlations of such a structure.

$$M = \begin{bmatrix} 1 & Corr(v_{12}) & Corr(v_{13}) & \dots & Corr(v_{1g}) \\ Corr(v_{12}) & 1 & Corr(v_{23}) & \dots & Corr(v_{2g}) \\ Corr(v_{13}) & Corr(v_{23}) & 1 & \dots & Corr(v_{3g}) \\ . & . & . & & . \\ Corr(v_{1g}) & Corr(v_{2g}) & Corr(v_{3g}) & \dots & 1 \end{bmatrix}$$

4. Experimental results

To verify the effect of our quiet aggressor and tree reduction techniques in distributed RC-π model, we have applied the proposed method to 7 noise-prone nets from a high-performance processor designed in a 0.15 micron process technology. In those nets, the drivers of the circuits were replaced by linear resistors using the technique described in [6]. Each piece of distributed circuitry consisting of 25 RC-π stages is used. Assume process variations in those nets are Gaussian and statistical independent.

Some information of the circuits and comparison of our model results with Spice simulation and simple approach proposed in [3] are shown in Table 1. The second column shows the number of total aggressor nets and number of switching aggressor nets. The third column is the total number of RC elements in a given circuit. The average number of all the nets is 154. The lengths of the victim nets in millimeters are shown in the fourth column with an average victim net length of 2.1mm. Table 1 shows that the average error of the peak noise voltage values calculated using the proposed model is 3.7%, while the simple approach has an average error of 9.1%. The proposed approach significantly improves the accuracy of crosstalk noise analysis with using the quiet aggressor and tree reduction in distributed RC-π model.

Table 1 Experimental results on peak noise voltage

Circuit	Na/Ns	#RC	Len(mm)	Spice(V)	Simple(Err%)	Proposed(Err%)
1	2/2	97	1.49	0.841	0.789(6.2)	0.889(5.7)

6	3/3	116	1.70	0.664	0.627(5.6)	0.643(3.2)
7	10/9	247	2.75	0.651	0.564(13.4)	0.613(5.8)
AVE	5.7/5.4	154	2.1	-	9.1%	3.7%

5. Conclusions

In this paper a new spatial correlation model based on the distributed RC-π model was presented. The merits of our approach include: 1) Quiet aggressor and tree reduction technologies in distributed RC-π model are proposed to reduce the complexity of circuit model; 2) A new spatial correlation model is proposed for random variables in reduced distributed RC-π model, which makes our method enable to consider effects of all the correlated and independent process variations. Experimental results show that compared to other methods our approach significantly improves the crosstalk analysis accuracy by handling a larger range of variables while maintaining the efficiency by using reduced distributed RC-π model.

Abstract. The minimum lethal dose of the children and adults taking aminophylline tablets and severe poisoning is discussed in the paper. Linear differential equations and function image are both introduced to analysis timely rescue methods of the human during poisoning. Meanwhile, modeling is provided and the model solution is given. In the end, the simulation results showed the fatal time of the smallest dose and effective rescue when taking aminophylline poisoning.

Introduction

The child has been mistakenly swallowed dose 100mg / tablets aminophylline eleven before two hours and he has vomiting, dizziness and other adverse symptoms. According to the Drug instructions, aminophylline dosage taken per adult is 100~200*mg*, children are 3~5*mg*, overdose can lead the blood concentration (dosage units of blood volume) too high. When the blood concentration is over100*ug/mg* there will be severe poisoning concentration; when the blood concentration is over 200*ug/mg*, it can lead to be fatal. Body taking certain drugs, blood plasma concentration is concerned to the total amount of blood. Typically, the total amount of blood is accounted for 7%~8% in the body weight and the blood is about 4000*ml* adult who weight is about 50~60*kg*. Now, the child's weight is about half of adult, so the blood can be considered about 2000ml. Thus, between the blood plasma concentration of the system and the amount of the drug can be converted to each other. The blood drug absorption and elimination rate can be determined by half-life. As can be seen from the manual, half-life of theophylline absorption is about 5 hours and half-life of exclude is about 6 hours.

Assumptions and model establishment

The drug transfer rate of the drug flowing into the blood in the gastrointestinal tract is proportional to $x(t)$, factor λ ($\lambda > 0$), the dose of 1100*mg* drug instantly flow into the gastrointestinal tract when $t = 0$. The drug exclusion rate of the drug in the blood is proportional to $y(t)$, factor μ(μ>0), no drug when $t = 0$.half-life of theophylline absorbed is 5 hours, exclude the period is 6 hours. The total amount of the child's blood is 2000*ml*.Model establishment is show in Figure 1.

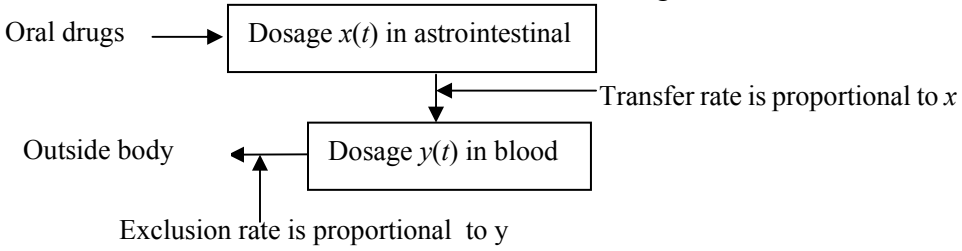

Figure 1. Model establishment

Where, $x(t)$ is lowering speed is proportional to $x(t)$, 1100mg drug flow into the gastrointestinal tract at the moment.

$$\frac{dx}{dt} = -\lambda x, \qquad x(0) = 1100$$

Growth rate of absorption $y(t)$ is λx, the speed reduced by the exclusion is proportional, where t=0 no drug in the blood.

$$\frac{dx}{dt} = \lambda x - \mu y, \qquad y(0) = 0$$

Model solving

$$\frac{dx}{dt} = -\lambda x, x(0) = 1100 \Rightarrow x(t) = 1100e^{-\lambda t}$$

The half-life of drug absorption is 5 hours.

$$\Rightarrow x(5) = \frac{x(0)}{2} \Rightarrow 1100e^{-\lambda t} = \frac{1100}{2} \Rightarrow \lambda = \frac{(\ln 2)}{5} = 0.1386(1/h)$$

$$\begin{cases} \dfrac{dy}{dt} = \lambda x - \mu y = -\mu y + 1100\lambda e^{-\lambda t} \\ y(0) = 0 \end{cases} \Rightarrow y(t) = \frac{1100\lambda}{\lambda - \mu}(e^{-\mu t} - e^{-\lambda t})$$

The half-life of the drug exclusion is 6 hours when considering only the blood of drugs excluded.

$$\Rightarrow \begin{cases} \dfrac{dy}{dt} = -\mu y \Rightarrow y(t) = ae^{-\mu(t-\tau)} \\ y(\tau) = a, y(\tau + 6) = \dfrac{a}{2} \end{cases} \Rightarrow \mu = \frac{\ln 2}{6} = 0.1155(1/h)$$

Results and analysis

The drug dose of the gastrointestinal tract is $x(t) = 1100e^{-0.1386t}$ and the drug doses of blood system is $y(t) = 6600(e^{-0.1155t} - e^{-0.1386t})$ and the total amount of the child's blood is 2000ml, so the following is given:

Case 1: Blood concentration serious poisoning is 100ug/ml and the drug content of the blood system is *y(t)*=2000ml×100ug=200mg;

Case 2: Blood concentration when fatal is 200ug/ml and the drug content of the blood system is *y(t)*=2000ml×200ug=400mg.

The Matlab program is as follows.

```
t=0:0.01:25;
y1=1100.*exp(-0.1386.*t);
y2=6600.*(exp(-0.1155.*t)-exp(-0.1386.*t));
plot(t,y1,'b',t,y2,'m');
xlabel('t/h');
ylabel('y/mg');
grid on;
legend('y1 curves of dose in gastrointestinal tract',' y2 curves of dose in blood ');
max(y2);
```

The change compared is showed in figures. *x(t)* and *y(t)* curves of dose level changing with time and gastrointestinal dose *x(t)*, blood dose *y(t)* of curves of dose level changing with time is showed in Figure 3.

It is showed from the figure 3, when t=1.62, the drug dose of blood system has been reach 200mg.so, it is very serious while the child was sent to the hospital in the medication after 2 hours.

$y(2) \approx 236.5mg > 200mg$

When t=4.87 hours the drug dose of blood system has been reach 400mg, which is a fatal. So, if the child is not promptly for treatment, he would be dead after 2.87 hours.

Rescue plan

1. Oral activated charcoal

Oral activated charcoal drug elimination rate is increased to two times of the original, then, μ=0.1155×2=0.2310.Child is rescued when he arrive at the hospital (t=2) , the blood of the dosage is marked as $z(t)$.

$$\frac{dz}{dt} = \lambda x - \mu z, t \geq 2$$

$$x = 1100e^{-\lambda t}, z(2) = 236.5$$

$$z(t) = 1650e^{-0.1386t} - 1609.5e^{-0.2310t}, t \geq 2$$

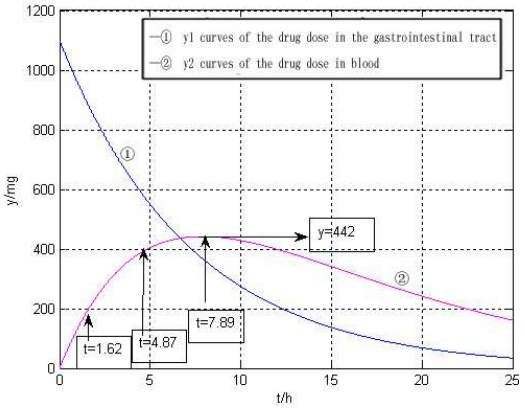

Figure 2. *x(t)* and *y(t)* curves of dose level changing with time

The Matlab program is as follows.

```
t=0:0.01:25;
t1=2:0.01:25;
y1=1100.*exp(-0.1386.*t);
y2=6600.*(exp(-0.1155.*t)-exp(-0.1386.*t));
y3=1650.*exp(-0.1386.*t1)-1609.5.*exp(-0.2310.*t1);
plot(t,y1,'b',t,y2,'m',t1,y3,'r');
xlabel('t/h');
ylabel('y/mg');
grid on;
legend('y1 curves of dose in gastrointestinal tract',' y2 curves of dose in blood  before intervening','y3 curves of dose in blood after intervening ');
```

Now, *x(t)* and *y(t)* curves of dose level changing with time is showed in Figure 3.

Analysis

From the *x(t)* and *y(t)* curves of dose level changing with time showed in figure 3,we find that the blood of the dosage after intervening *z(t)* is well below critical levels *y(t)*, $z(t)_{\max} = 318$. Although the use of oral activated charcoal adsorption method make the blood of the dosage *z(t)* rising was continued for some time, while when t=5.26 it began to drop, which show that the drug elimination rate increased is not enough.

2. Vitro blood dialysis

Hemodialysis makes the drug elimination rate increased to 6 times of the original. Then, μ=0.1155×6=0.693. Child is rescued when he arrive at the hospital (t=2) , the blood of the dosage is marked as $z'(t)$. then, $z'(t) = 275e^{-0.1386t} - 275e^{-0.2310t}, t \geq 2$.

The Matlab program is as follows.

```
t=0:0.01:25;
t1=2:0.01:25;
y1=1100.*exp(-0.1386.*t);
y2=6600.*(exp(-0.1155.*t)-exp(-0.1386.*t));
```

```
y3=275.*exp(-0.1386.*t1)-275.*exp(-0.693.*t1);
plot(t,y1,'b',t,y2,'m',t1,y3,'r');
xlabel('t/h');
ylabel('y/mg');
grid on;
legend(('y1 curves of dose in gastrointestinal tract',' y2 curves of dose in blood  before intervening",'y3 curves of dose in blood after intervening');
```

Now , *x(t)* ,*y(t)* and *z'(t)* Curves of dose level changing with time is showed in Figure 4.

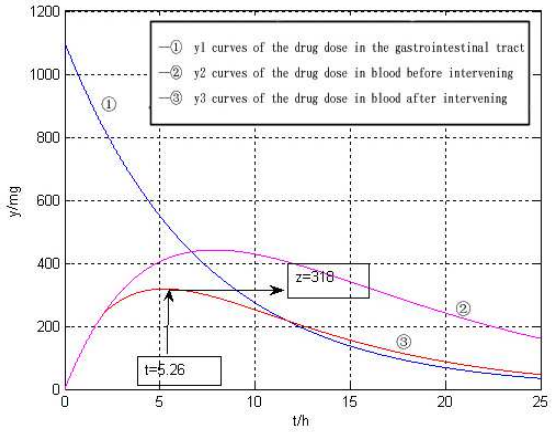

Figure 3. *x(t)* and *y(t)* curves of dose level changing with time

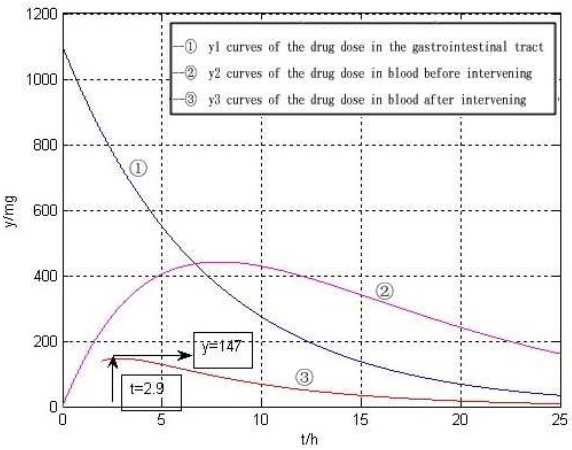

Figure 4. *x(t)* ,*y(t)* and *z'(t)* curves of dose level changing with time

Analysis:

From *x(t)* ,*y(t)* and *z'(t)* Curves of dose level changing with time showed in figure 4,we find that the blood of the dosage declined faster after Hemodialysis, when *t*=2.9 it begin declining and the blood of the dosage *z'(t)* is Significantly below *y(t)* and *z'(t)* is Significantly below lethal levels. $z'(t)_{\max} = 147$.

Abstract. As for the problem of maneuvering target tracking in the clutter environment, this paper combines IMM with PHD and realizes it through approach of particle filter. This algorithm avoids the troublesome problem of data association, and takes advantage of probability hypothesis density (PHD) filter in tracking maneuvering targets and interacting multi-model (IMM) algorithm in the field of model switching effectively, in the clutter environment, the status of the targets can be estimated precisely and steadily. This paper compares the proposed filtering algorithm with the classical IMM algorithm in performance, and the simulation results show that, the improved filtering algorithm has good tracking performance and tracking accuracy.

Introduction

Multiple target tracking in cluttered environment usually needs the data association calculation to determine the correspondence between the observations and the targets[1], the traditional multi-target tracking algorithm based on the association generally require known the number of targets, and the movement of each target is independent, but the increase of number of clutters or targets often leads to the phenomenon of loss and misuse of target, thus making the algorithm fail. Based on this, Mahler proposed the probability hypothesis density (PHD) filter method[2]. PHD filter is different from the traditional multi-target tracking algorithm that based on data association, PHD filter uses a recursive method to deliver the target state distribution of information, thus avoiding the calculation of complex data association, and can get the number of multi-objective and state estimation in the distribution information of target state. For linear Gaussian problem, Vo gives a closed recursive form for PHD filter: GM-PHD filter[3], while for the nonlinear non-Gaussian system, Vo also gives the particle filter implementation for PHD filter: SMC-PHD filter, the basic idea is using the set of points of weighted random sampling to characterize the PHD distribution[4].

This paper reviews the probability hypothesis density filter method and combines the IMM and particle PHD to get the IMM-PHD filter that can track multiple targets. Through the full use of the superiority of IMM algorithm[5-6] in maneuvering target tracking and the superiority of random set theory in an unknown number of multiple target areas, and the combination of statistical theory of random sets and interactive multi-model approach, this paper has verified the feasibility and effectiveness of the algorithm by MATLAB simulation.

The Sequential Monte Carlo IMM-PHD Filter

A. Probability hypothesis density filter (PHD filter)

1) Prediction: The predicted PHD is given by

$$D_{k|k-1}(x_k \mid Z_{1:k-1}) = \gamma_k(X_k) + \int [e_{k|k-1}(x_{k-1}) f_{k|k-1}(X_k \mid X_{k-1}) + b_{k|k-1}(X_k \mid X_{k-1})] \times D_{k-1|k-1}(X_{k-1} \mid Z_{1:k-1}) dx_{k-1} \tag{1}$$

2) Update: The updated PHD at time step k is given by

$$D_{k|k}(X_k \mid Z_{1:k}) \cong [\sum_{z_k \in Z_k} \frac{p_D(x_k) f_{k|k}(z_k \mid x_k)}{\lambda_k c_k(z_k) + \psi_k(z_k \mid Z_{1:k-1})} + (1 - p_D(x_k))] \times D_{k|k-1}(x_k \mid Z_{1:k-1}) \tag{2}$$

Where the likelihood function $\psi_k(Z_k \mid Z_{1:k-1})$ is given by

$$\psi_k(z_k \mid Z_{1:k-1}) = \int p_D(x_k) f_{k|k}(z_k \mid x_k) D_{k|k-1}(x_k \mid Z_{1:k-1}) dx_k \tag{3}$$

B.IMM-PHD

1) The Mixing Stage: In this stage, each mode-matched filter is fed with a different density that is a combination of the previous mode-dependent densities.

$$\tilde{D}_{k|k-1}(x_{k-1}, r_k = q \mid Z_{1:k-1}) = \sum_{p=1}^{N_r} D_{k-1|k-1}(x_{k-1}, r_{k-1} = Z_{1:k-1}) h_{pq}, q = 1,\ldots,N_r \tag{4}$$

2) The Prediction Stage:

$$D_{k|k-1}(x_k, r_k = q \mid Z_{1:k-1}) = \gamma_k(x_k, r_k = q) +$$
$$\int [e_{k|k-1}(x_{k-1}) f_{k|k-1}(x_k \mid x_{k-1}, r_k = q) + b_{k|k-1}(x_k \mid x), r = q] \times \tilde{D}_{k|k-1}(x_{k-1}, r_k = q \mid Z_{1:k-1}) dx_{k-1} \tag{5}$$

3) The Update Stage:

$$D_{k|k}(x_k, r_k = q \mid Z_{1:k}) \cong [\sum_{z_k \in Z_k} \frac{p_D(x_k) f_{k|k}(z_k \mid x_k, r_k = q)}{\lambda_k c_k(z_k) + \psi_k(z_k \mid Z_{k-1})} + (1 - p_D(x_k))] \times D_{k|k-1}(x_k, r_k = q \mid Z_{1:k-1}) \tag{6}$$

Where the likelihood function $\psi(\cdot)$ is given by

$$\psi_k(z_k \mid Z_{1:k-1}) = \int p_D(x_k) f_{k|k}(z_k \mid x_k, r_k = q) D_{k|k-1}(x_k, r_k = q \mid Z_{1:k-1}) dx_k \tag{7}$$

C. Sequential Monte Carlo Implementation

Let the posterior IMMPHD be represented by a set of particles $\{w_{k-1}^{(s)}, x_{k-1}^{(s)}, r_{k-1}^{(s)}\}_{s=1}^{L_{k-1}}$:

$$D_{k-1|k-1}(x_{k-1}, r_{k-1} \mid Z_{1:k-1}) = \sum_{s=1}^{L_{k-1}} w_{k-1}^{(s)} \delta(x_{k-1} - x_{k-1}^{(s)}, r_{k-1} - r_{k-1}^{(s)}) \tag{8}$$

Where $\delta(\cdot)$ is the Dirac Delta function.

1) Prediction:

$$r_{k|k-1}^{(s)} \sim \begin{cases} \pi_k(\cdot \mid r_{k-1}) & s = 1,\ldots, L_{k-1} \\ \beta_k(\cdot) & s = L_{k-1} + 1,\ldots L_{k-1} + J_k \end{cases} \tag{9}$$

Where $\pi(\cdot \mid r_{k-1})$ and $\beta_k(\cdot)$ are probability mass functions, $\{r_{k|k-1}^{(s)}\}_{s=1}^{L_{k-1}}$ are independent and identically distributed model

samples.Then, the predicted IMMPHD is given by

$$\tilde{D}_{k|k-1}(x_{k-1}, r_k \mid Z_{1:k-1}) = \sum_{s=1}^{L_{k-1}+J_k} \varpi_{k|k-1}^{(s)} \delta(x_{k-1} - x_{k-1}^{(s)}, r_k - r_{k|k-1}^{(s)}) \tag{10}$$

Where

$$\varpi_{k|k-1}^{(s)} = \begin{cases} \frac{f_{k|k-1}(r_{k|k-1}^{(s)})}{\pi_k(r_{k|k-1}^{(s)})} w_{k-1}^{(s)} & s = 1,\ldots, L_{k-1} \\ \frac{\theta_k(r_{k|k-1}^{(s)})}{\beta_k(r_{k|k-1}^{(s)})} \frac{1}{J_k} & s = L_{k-1} + 1,\ldots, L_{k-1} + J_k \end{cases} \tag{11}$$

In Eq. 11, the probability mass function $\theta_k(\cdot)$ denotes the model distribution of spontaneous target births at time step k.

We now apply importance sampling to generate state samples that approximate the predicted IMMPHD $D_{k|k-1}(x_k, r_k \mid Z_{1:k-1})$:

$$x_{k|k-1}^{(s)} \sim \begin{cases} q_k(\cdot \mid x_{k-1}, r_{k|k-1}, Z_k) & s = 1,\ldots L_{k-1} \\ p_k(\cdot \mid r_{k|k-1}, Z_k) & s = L_{k-1} + 1,\ldots, + J_k \end{cases} \tag{12}$$

Then, the weighted approximation of the predicted IMMPHD is given by

$$D_{k|k-1}(x_k, r_k \mid Z_{1:k-1}) = \sum_{s=1}^{L_{k-1}+J_k} w_{k|k-1}^{(s)} \delta(x_k - x_{k|k-1}^{(s)}, r_k - r_{k|k-1}^{(s)}) \tag{13}$$

Where

$$w_{k|k-1}^{(s)} = \begin{cases} \frac{e_{k|k-1}(x_{k|k-1}^{(s)}) f_{k|k-1}(x_{k|k-1}^{(s)} \mid x_{k-1|k-1}^{(s)}, r_{k|k-1}^{(s)}) + b_{k|k-1}(x_{k|k-1}^{(s)} \mid x_{k-1|k-1}^{(s)}, r_{k|k-1}^{(s)})}{q_k(x_{k|k-1}^{(s)} \mid x_{k|k-1}^{(s)}, r_{k|k-1}^{(s)}, Z_k)} \varpi_{k|k-1}^{(s)} & s = 1,\ldots L_{k-1} \\ \frac{\gamma_k(x_{k|k-1}^{(s)} \mid r_{k|k-1}^{(s)})}{p_k(x_{k|k-1}^{(s)} \mid r_{k|k-1}^{(s)}, Z_k)} \varpi_{k|k-1}^{(s)} & s = L_{k-1} + 1,\ldots L_{k-1} + J_k \end{cases} \tag{14}$$

2) Update: With the available set of measurements Z_k at time step k, the updated particle weights can be calculated by

$$w_k^{*(s)} = \left[(1 - p_D(\mathrm{x}_{k|k-1}^{s})) + \sum_{i=1}^{N_k^Z} \frac{p_D(\mathrm{x}_{k|k-1}^{(s)}) f_{k|k}(\mathrm{z}_k^i \mid \mathrm{x}_{k|k-1}^{(s)}, r_{k|k-1}^{(s)})}{\lambda_k c_k(\mathrm{z}_k^i) + \Psi_k(\mathrm{z}_k^i)} \right] w_{k|k-1}^{(s)} \tag{15}$$

Where

$$\Psi_k(z_k^i) = \sum_{s=1}^{L_{k-1}+J_k} p_D(\mathrm{x}_{k|k-1}^{(s)}) f_{k|k}(\mathrm{z}_k^i \mid \mathrm{x}_{k|k-1}^{(s)}, r_k^{(s)}) w_{k|k-1}^{(s)} \tag{16}$$

3) Resample: When perform resampling, the expected number of targets is calculated by summing up the total weights

$$\hat{n}_k^X = \sum_{s=1}^{L_{k-1}+J_k} w_k^{*(s)} \tag{17}$$

Now, the discrete approximation of the updated posterior IMMPHD at time step k is given by

$$D_{k|k}(\mathrm{x}_k, r_k \mid Z_{1:k}) = \sum w_k^{(s)} \delta(\mathrm{x}_k - \mathrm{x}_k^{(s)}, \mathrm{r}_k - \mathrm{r}_k^{(s)}) \tag{18}$$

Simulation Analyses

Conducting the experiment in the two-dimensional monitoring region [-20000, 20000]×[-20000, 20000]. Give two models of target motion parameters: set up the sampling interval as T, the probability of target detection as $P_D = 1$, and no false alarm exists, in the Cartesian coordinate system, the target separated motion model and observation model that do uniform motion is $X(k+1)=FX(k)+GW(k)$, $Z(k)=C(k)X(k)+V(k)$,parameters of the uniform linear motion and the uniform circular motion models are:

$$F1=\begin{bmatrix} 1 & T & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & T \\ 0 & 0 & 0 & 1 \end{bmatrix} C1=\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} G1=\begin{bmatrix} \frac{T^2}{2} & 0 \\ T & 0 \\ 0 & \frac{T^2}{2} \\ 0 & T \end{bmatrix} \text{and}$$

$$F2=\begin{bmatrix} 1 & T & 0 & 0 & \frac{T^2}{2} & 0 \\ 0 & 1 & 0 & 0 & T & 0 \\ 0 & 0 & 1 & T & 0 & \frac{T^2}{2} \\ 0 & 0 & 0 & 1 & 0 & T \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix} C2=\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \end{bmatrix} G2=\begin{bmatrix} \frac{T^2}{4} & 0 \\ \frac{T}{2} & 0 \\ 0 & \frac{T^2}{4} \\ 0 & \frac{T}{2} \\ 1 & 0 \\ 0 & 1 \end{bmatrix}$$

The sampling period is 2s, conduct observation on x and y independently, standard deviation of noise observation is 100m, the centripetal acceleration is 5m/s. Figure 1 and Figure 2 are the simulation results.

(a) Classic interactive model filtering algorithm (b) The improved filter algorithm

Fig.1 RMSE in x direction

(a) Classic interactive model filtering algorithm (b) The improved filter algorithm

Fig.2 RMSE in y direction

It can be seen from Fig.1, the improved filtering algorithm's tracking accuracy is superior to the general interacting multiple model filtering algorithm's in the x direction, and the same can be seen from Fig.2, the improved filtering algorithm's error standard difference is also less than the classic interacting multiple model filtering algorithm's in the y direction.

In the simulation, the general IMM filtering algorithm and interactive multi-model probability hypothesis density filter algorithm with sequential Monte Carlo sampling method are compared. The position estimation error standard deviation curve of IMM-KF filter algorithm and the IMM-PHD filter algorithm are given above. At the beginning, the filtering error is greater, but as time goes on, the filtering error has been reduced, and gradually approached the true trajectory estimate. And from the above comparison figures, it is clear that the filtering results of use the probability hypothesis density (PHD) with interactive multiple model (IMM) filtering algorithm is better than the filtering results of using the interacting multiple model (IMM) filtering algorithm of general kalman filtering method.

Conclusions

Taking into account the nonlinear non-Gaussian case in multi-target tracking in clutter, this paper uses sequential Monte Carlo method to conduct IMM-PHD filter, PHD filter effectively reduces the complex calculation in target tracking, and SMC sampling method can make the filter operate in nonlinear non-Gaussian condition. This paper uses an interactive multi-model, which can enhance the accuracy of filter for handling maneuvering target greatly. By comparing IMM-KF filter and SMC-IMMPHD filter, the simulation experiment shows that the use of SMC-IMMPHD comparison algorithm can effectively improve the effect of multi-target tracking.

Keyword: grey system, mathematical model

Abstract: Professional skills are important to students who major in ideological and political education. They must be able to conduct the tasks required by the teaching of political activities. Evaluation of the student's skills can offer a theoretical basis for measuring a ideological and political course, but an effective evaluation method is lacking. Therefore, an evaluation method based on the grey system theory is proposed in this article. First, the educational structure of the ideological and political education is discussed; second, the mathematical model of grey system theory is presented; and third, the structure of the professional skills evaluation model of students majoring in ideological and political education is presented. The evaluation index system, the results of which are drawn from a questionnaire distributed to 800 students, and the evaluation program, is put forward. A case study was carried out, the results of which show that the evaluation method outlined here can contribute to improving overall standards in the course.

Introduction

The grey system theory, initiated in 1982, is the mathematical theory that solves problems where there is incomplete information. The grey system theory can be used to crystallize and quantify the evaluation of students' abilities on ideological and political education courses. Conclusions can be drawn from the data even though all of the underlying rules are not understood.

Grey relational analysis is a new method in the grey system theory. In grey relational analysis a system with no information is black and a system with perfect information is white; these extremes are unlikely in real situations. Grey relational analysis is used to analyse the relationships between the various factors of a system.

At present, the gray forecast method has been used in agriculture, energy, ecology, environment, economy, finance and other fields, and solves a large amount of the problem, reflects the important theoretical research and practical application value. Many scholars discuss research and develop for the use of grey forecasting model, the research and development. Such as Li Yueqiu (2013) combindwith a concrete instance. According to grey forecasting model, multiple prediction methods are proposed, and the advantages and disadvantages of each method are summarized. Chen Jinlong (2010) used GM (1, 1) grey forecasting model to forecast the non-performing loans of commercial Banks, and the relevant financial institutions operating conditions of early warning. Family filial piety jung (2010) in gansu province in recent years, analysis GDP data, GM (1, 1) prediction model is established, the empirical test shows that the prediction model is reliable.

With the expansion of higher education in China, improving students' education is a key goal. Higher education should focus on developing both the innovative and practical abilities of students, as well as their personal and academic qualities. In recent years, there has been a high demand for students studying ideological and political education. ideological and political education skills are necessary for all sporting activities and students studying ideological and political education. should havegood practical skills for observation, expression and communication [1].

The ideological and political education. student's professional goal is to teach and to provide guidance. At present there are disadvantages for the ideological and political education students in

developing their skills and evaluating their abilities on ideological and political education courses. Reform of teaching must be continued and deepened, so as to improve students' skills.
The relational degree is a measure of the relationship between all factors and can be used to evaluate PE students' abilities. There are many uncertainties in evaluating the abilities of PE students, and this implies that students' abilities can be regarded as grey, and suitable for analysis using the grey system theory.

Students Majoring In

The abilities of students studying PE are poor and do not meet the requirements of colleges or society. This affects their employment opportunities. The problems with PE teaching are as follows [2]:

First, the structure of the curriculum is inappropriate and the basics are not properly emphasised. The time allocated to different components of the course is incorrect, and the theoretical and technical subjects are not properly arranged. The course content is bland and the scope is narrow.

Second, the teaching of the practical sessions is weak. The teaching of practicals is dominated by practice as it should be but should not be limited to it; for example, the graduate may be expected to engage in physical activities in society and in group fitness instruction. The range of the practical teaching is narrow and the time spent on it short. The time allocated to practicals is not adequate and the feedback is insufficient.

Third, extracurricular activities are not properly integrated into the course, with inadequate support for sports clubs and sports associations, etc. Therefore, the PE students are not being exposed to enough extracurricular opportunities.

Training is similar to systems engineering, in that it centres on the design and management of a complex project over a life cycle and an evaluation of the results, i.e. improving students' skills. The teaching of the PE could be evaluated to determine the main problems. Metrics could then be used to optimize the course structure to obtain the best outcomes for students.

The Mathematical Model: Grey System Theory

The grey equation can be used to describe the characteristics and evolution of a grey system. The analysis of grey system theory is quantitative analysis based on GM model, GM(1,1) model is the most commonly used at present. Set a list of primary data as

$$x^{\{0\}} = \left\{x^{\{0\}}(1), x^{\{0\}}(2), \ldots, x^{\{0\}}(n)\right\}$$

accumulate to the above data, 1-GAO sequence is obtained

$$x^{\{1\}} = \left\{x^{\{1\}}(1), x^{\{1\}}(2), \ldots, x^{\{1\}}(n)\right\}$$

Among which $x^{\{1\}}(k) = \sum_{i=1}^{k} x^{\{0\}}(i)$

Grey SystemAnalysis

The grey system analysis includes grey relational analysis, grey cluster analysis and grey decision analysis [3]. The grey relational analysis can be applied to situations where the data are limited and grey. The basic idea is as follows: similarity of series curves is used to judge whether a relationship is close, and the grey relational degree is used to measure the closeness. Grey relational analysis requires limited calculations and yields reliable results; it has been used, for example, in engineering.

Grey cluster analysis gathers observations into several definable classifications according to the white weight function. Grey cluster analysis has two methods as follows: The first method is grey relational cluster analysis, which is applied when merging comparable factors to simplify a complex system.

An index can denote several close relationships or a factor can include several other factors to describe the information without serious loss. The second method is the grey white weight function cluster, which is applied to judge whether the object belongs to a different classification.

The grey decision is obtained using the grey coefficient combined with the grey model. The effect is calculated using two methods; first: the measure is based on GM (n, k) ; second: the measure is obtained by extending the relational coefficient. The measure of grey can be optimal or suboptimal situations.

Determination of an Evaluation Index System

Measurement of the skills of students is by their performances at practical activities during four years at college. These reflect the physiological qualities and psychological characteristics required by their teaching. Physical skills, at the core of teaching physical activities, develop alongside students' intellectual abilities.

The evaluation index of student skills was obtained by a questionnaire survey, and a literature review. The subjects were 800 college students, from 30 colleges, majoring in physical education. Of the 800 questionnaires issued, 759 were returned, for a response rate of 95%. An extensive literature review was also conducted, as shown in figure 1.

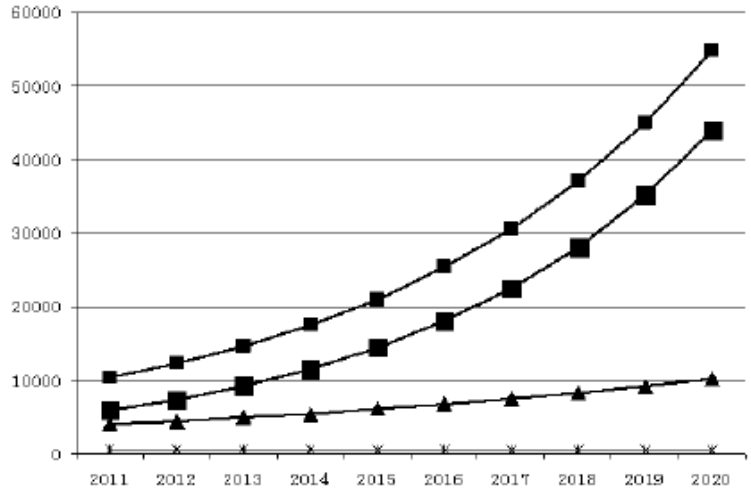

Fig. 1 Evaluation index of student skills

Case Study

The data from 800 college students majoring in PE in 30 colleges were used to carry out an empirical analysis, using the grey system theory. The weights of second degree indices were calculated according to Formula (19), and the results are shown in Table 1.

Table 1. Weight of second grade indices

Second grade	Weight	Second grade	Weight
(I11)	0.21	(I41)	0.09
(I12)	0.25	(I42)	0.23
(I13)	0.23	(I43)	0.22
(I14)	0.31	(I44)	0.11
(I21)	0.17	(I45)	0.35
(I22)	0.22	(I51)	0.14
(I23)	0.14	(I52)	0.42
(I24)	0.21	(I53)	0.23
(I25)	0.26	(I54)	0.21
(I31)	0.24	(I61)	0.15
(I32)	0.21	(I62)	0.32
(I33)	0.32	(I63)	0.14
(I34)	0.23	(I64)	0.39

The relational degree of the first degree indices can be calculated according to Formula (21) and the results are shown in Table 2.

Table 2. Relational degree of first degree indices

First degree	Relational
I1	0.557
I2	0.643
I3	0.518
I4	0.421
I5	0.446
I6	0.384

The first degree indices are ranked as follows: I2 > I1 > I3 > I5 > I4 > I6. As can be seen from the results, physical teaching is essential in improving the abilities of students majoring in physical education. Therefore, training in physical teaching should be a focal point of the PE course.

Other skills should be developed at the same time, and the evaluation results should offer a theoretical base for training students majoring in PE. This points the way to further reform in teaching PE.

Conclusions

A qualitative and quantitative analysis, based on the grey system theory, was carried out to evaluate the skills of students majoring in physical education[4]. The evaluation index system was verified, using questionnaire data and the first- and second-degree indices were obtained. The ranking of the indices was evaluated and a teaching reform measurement determined. This provides a mechanism by which to improve the abilities of students majoring in physical education.

Ideological and political education linear regression theory

Meng Zhang

Editorial Department of journal, Xinxiang university, Henan ,China,453003
837457026@qq.com

Keyword: linear regression, mathematical model

ABSTRACT: The paper presents a valid and efficient method to teach ideological and political education courses in linear regression analysis. It includes theory and practice parts, where interactive learning methodologies are created. It adopts case-study teaching, since this teaching method effectively integrates theoretical teaching and practical teaching. The lectures should be not an exhaustive review of regression methodology, but they should focus on how the regression models derived. Moreover, the teacher should pay more attention to the theoretical aspects of models rather than to their implementation using software. Students work in teams of three or four on a problem presented by teachers and choose relevant software to carry out their own projects. Feedback from students indicates that this method of teaching improves students' class attendance and greatly increases their interest in learning.

0 Introduction

To study the ideological and political education curriculum theory a series of problems, we need to first clarify the meaning of the theory of ideological and political education course which also needs to interpret one of the first core word "ideological and political education" and "curriculum theory". We know that the ideological and political education is a comprehensive and complex concept, its connotation can smaller of bigger. Broad ideological and political education is almost equivalent to the thought education, political education, moral education, discipline education and shape people's ideological consciousness, such as political ideas, moral character and spirit of citizenship which is related to the comprehensive education category. And narrow sense of ideological and political education is a proper noun, and led by the proletariat political party, in order to cultivate qualified builders and reliable successors of revolution and construction the education goal of closely linked together the ideology of class consciousness and the political thought education. The concept of curriculum theory is often seen as a education subject manages research area and branch, in China for nearly a century of research history. So far, education science field discussion of curriculum and curriculum theory connotation is still on. But according to one of the most common explanation, course can be interpreted as a subject, teaching material and teaching related expression, can realize the goal of school education ,curriculum theory is of course the proprietary theory, is the school discipline and curriculum system and content structure.

Reality requires one to deal with a range of variables. Students can encounter many variables for a problem, including relationships between the variables[1].Commonly, these problems can be divided into two kinds according to their relationship. One is the problem of determining, which relationship can be expressed using the functions available. Another is not completely determined by using functions, but with random variables. This kind of relationship is called co-relationship. Regression analysis is a method to study the relationship between variables. So one builds regression models to help understand and explain the relationships. Regression models can also be used to predict actual outcomes.

The earliest form of regression was the method of least squares, which was published by Legendre in 1805 and by Gauss in 1809. Legendre and Gauss both applied the method to problems of determining. The term *regression* was coined by Francis Galton in the 19th Century to describe a biological phenomenon. However, Francis Galton applied the method to the problem of random variability[2].The phenomenon was that the heights of descendants of tall ancestors tend to regress down towards a normal average, and this is, known as regression toward the mean.

Today, regression methods continue to be an area of active research, and new methods have been developed for robust regression, regression involving correlated responses, such as time series and growth curves, regression in which the predictor or response variables are curves, graphs, images or other complex data objects, etc. There are many examples. Feilong and Yubo made an error analysis for the linear programming support vector regression problem in learning theory. Jose M. proposed a machine learning algorithm for regression problems. Qing, H. et al presented parallel extreme learning machine for regression based on MapReduce[3] .

Chen Y. proposed assessing mathematics learning achievement using hybrid rough set classifiers and multiple regression analysis. González-Recio and Forni proposed Genome-wide prediction of discrete traits using Bayesian regressions and machine learning. Tsuruoka et used logistic regression to study learning string similarity measures . Therefore, almost all institutions in which relevant majors have been set offer a course in regression. For example, MIT offers open courseware. In addition, a large number of open on-line teaching resources can also be found, such as applied regression analysis at Columbia Business School for the MBA major.

In 2010, a statistics major was established in the Mathematics and Computer School at Xinxiang University, Xinxiang, China[4].In this year, the School first offered the course for students whose major came from computer science or mathematics. It is compulsory for mathematics students, while it is an elective for computer science students.

1 linear regression model

The theory-oriented lectures cover single linear regression and multiple linear regressions. Students learn what regression is, how to create its mode, how to estimate the parameters of the model (Estimation Using Least Squares), understanding the assumptions of establishing the conditions for the model, what the regression coefficients are, how to compare the models, and predicting and controlling using regression model. Teachers start theirs lectures with a discussion of simple regression, then, move on to multiple linear regression. This is quite reasonable from a pedagogical point of view, since simple regression has the great advantage of being easy to understand graphically.

Students should place a lot of emphasis on the simple linear regression analysis and understanding its mathematical expressions and be open to more sophisticated concepts. It is difficult for students to study multiple linear regression analysis. However, it is a primary tool in the analysis of real data. Thereby, single linear regression is taught in six sessions, while multiple linear regression requires four sessions. A session is 90 minutes' duration.

Single linear model describes a linear relationship between two variables. One is called the target, response or dependent variable, and is usually represented by y . Another is called the predicting or independent variables, and is usually represented by x . Given $(x_1, x_2, , x_N)$, the simple linear regression model is described as:

$$B = (\sum XY - \frac{1}{n}\sum X \sum Y) / [\sum X^2 - \frac{1}{n}(\sum X)^2]$$

$$A = \frac{1}{n}(\sum Y - B\sum X)$$

where the data, x_i , y_i , represent a random sample from a larger population, which consist of n set of observations, the coefficients are unknown parameters, and $_i$ are random error or disturbance terms.

2 Feedback Exercises

In the spring semester of the 2012/2013 term, a total of 60 junior students came from two majors,, joined the course at the Xinxiang University, Xinxiang, China. These students already had joined some previous courses, such as mathematical analysis, advanced algebra, probability and statistics, etc [5]. They also demonstrated a certain level of operating computer software capability. A survey questionnaire with six feedback questions was administered to all of these students (shown in Table 1).

Table 1 Feedback questions

Questions		Majors		Mean
		Computer science (students 30)	Mathematics (students 30)	
1	I became interested in data analysis through this class.	27 (90%)	28 (93%)	92%
2	I understand the concept of linear regression.	24 (80%)	26 (87%)	83%
3	I performed the linear regression using MATLAB program.	27 (90%)	26 (87%)	88%
4	I performed the linear regression using MS Excel.	29 (97%)	29 (97%)	97%
5	I think the practice is useful to understand the concept of linear regression.	30 (100%)	30 (100%)	100%
6	I can apply my knowledge of mathematics by performing the experiment.	24 (80%)	25 (83%)	82%

There are too many formulations about regression analysis. It is often difficult to understand these concepts of regression analysis, said some students. As can be seen from student feedback, only 80% of computer science students can understand regression, while 87% of mathematics students can do so. However, almost students finished their experiments, and all of them think the practice is very useful to understand those concepts. This information shows that students' interest will be enthused if theory is combined with practice, and as long as theory explanation is not ignored.

Conclusion

Regression analysis is not only a statistical process for estimating the relationships between variables, but it is also widely used for prediction and forecasting. It is difficult to acquire this knowledge, because it is necessary for undergraduates to have fundamental mathematics and operating computer skills. It includes many techniques for modeling and analyzing several variables.

However, the lectures should be not an exhaustive review of regression methodology, but should focus on how the regression models are derived. In the teaching process, giving hands-on experience to students is necessary. The teacher should pay more attention to the theoretical aspects of models rather than to their implementation using software. In the process of teaching, these will help to improve the teaching effect.

Keywords: genetic algorithm; vehicle dispatcher;

Abstract: The traditional genetic algorithm has the disadvantages that hinder the development and promotion of vehicle dispatcher and slow retard the development speed of logistics industry. Through the research of vehicle dispatcher's demand, we have put forward a new genetic algorithm which is improved, effective and adept to the normal vehicle dispatcher. We have proved that this algorithm is feasible and effective by analyzing the examples.

0 Introduction

The Genetic Algorithm is firstly proposed by J.Holland, and re-identified and deduced by Hollanl later on. Its core idea is every outstanding individual will appear the directionof index increasing in every dynamical population biology[1].That is to say, it is convergent, so it can be applied in practice preferably. This algorithm is a randomly searching and calculating method which has better adaption and flexible optimized object, so we do not need the successive optimized object, or the optimized object to differentiate, or has the good stability and parallel searching ability. At the same time, the genetic algorithm does not need the initial solution, and arbitrary initial population biology can operate and outcome.We use randomized optional strategy in this algorithm, that is to say, it makes the outstanding individual go to the next generation through the survival of the fittest, and then after the cross - fertilization and Genetic behavior, it realizes weakness or disappearance.

Compared to other algorithms, the genetic algorithm has its own merits[2]. The genetic algorithm adopts the evolution mechanism, and it carries out the searching process in the whole situation, averting the localization. Even if the adaptivefunction is discontinuous or irregular, the genetic algorithm can find the optimized solution of whole situation. And also, it has wonderful parallel processing and can realize the combination with other algorithms, especially adapted to the issues which has large scale and broad distribution.

In order to realize the optimization of vehicles dispatching, the main content of genetic algorithm is as follows: (1) give the researching object number. Only when we transform the spatial data issue into a bunch of genes data which can be dealt with by this algorithm can we use the genetic algorithm to handle this problem for the genetic algorithm has poor handling ability to spatial problems.(2)Initialize the population biology. In order to achieve the operation of the spatial problems, we must optionally transform the spatial problems into population biology which has many individuals, and these individuals can response the answer of one space optimized issue. Thus, the key issue is how to form the initialized population biology. (3) Using the fitness function. Every individual in the transformed population biology will affect the merits of the whole issue. So we have to use the fitness function to evaluate the individuals' ability, and apply the data to other genetic operation. (4) Select the excellent individual. In the genetic algorithm, only the excellent past age can have great meaning to the younger generation, causing the great individual and gene can multiply the greater generation. (5) Intersect and form the new individual. The intersection of single gene can influence the astringency and shorten the calculating time. We select the individual

having the good genes to intersect with the better genes and get the greater gene combination. Generally, the intersection has two steps. Firstly, we should pair the last generation randomly, and confirm the intersection point of these individuals which can be paired randomly, then transform or intersect the partial information, and then produce the new individual.

2 The Improved Genetic Algorithm

There are many ways to improve the traditional genetic algorithm [3]. In this paper, we improve and renew the genetic algorithm on the code structure, improve the intersecting and compiling operation, and expand the population biology at last. There are four aspects to be improved in total, and each on is as follows:

Step1. Improving the code program. We choose the order of natural number to code the chromosome for the the solution structure of the vehicles dispatching is particular. The whole dispatching internet built by the customer n needs m cars to realize the delivery. And then code the chromosome to a data whose length is n+m-1, the n natural numbers realize that it marks the full permutation with m+1 naughts, such as

$$0, i_1, i_2, ..., 0, i_f, ..., i_k, 0, ..., 0, i_p, ..., i_q, 0$$

in that I_j is the customer j on some wire, and o represents the DC(distribution center). The chromosome structure after the coding can represents that the vehicles send $i_1, i_2, i_3, ..., i_c$ from the DC and then return to the DC, which forms the first subsidiary dispatching internet. And then the second is also the same, forming the second subsidiary dispatching internet. Going along like this, all the customer can be visited. This subsidiary dispatching internet formed by the chromosome is not in order, while the particularly ordered subsidiary dispatching internet is the solution of the vehicles dispatching process.

Step2.we insert 0 into the former one or the later one. Going along like this till we get a lot of individuals in the population biology. Mark 8 as the customer and we need 2 vehicles. The process of coding the chromosome is shown in fig.2.

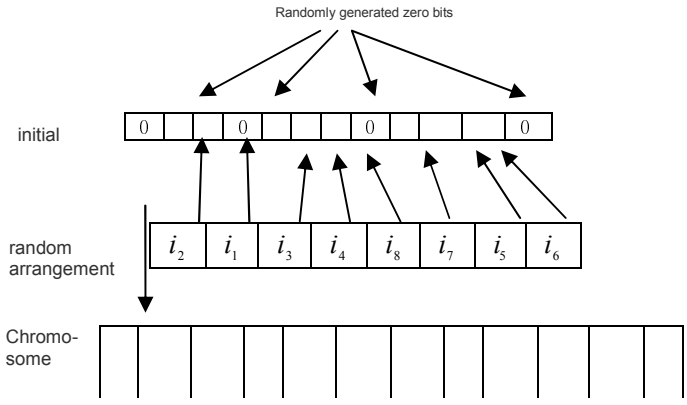

Fig 1.The code of chromosome initialization

Step3. Improving the fitness evaluation. The fitness evaluation of improved genetic algorithm is the same with the target function under the constraint model. The smaller sufficiency of the individual in the population biology is, the better is.

Step4. Improving the chosen operation. When we calculate the sufficiency of the individual using the improved fitness function, firstly we need to reorder them according to their values, big or small. Supposing the scale of the population is p, mark the individual having the smaller sufficiency as 0, the biggest as P-1.Randomly produce a number r conforming to the standard normal distribution, making $r* = |\frac{r}{3}|$, if the r we produced is greater than 3 we need to reproduce a r which satisfy the conditions. The probability of standard normal distribution of the randomized number between -3 and 3 is 99.9%.In this situation, $r*$ is located between 0 and 1, satisfying $t = r*(p-1)$.Supposing chromosome NO.t is chosen to the new population, the probability that the chosen chromosome is

closer to the symmetry axis 0, the bigger the excellent population. The value probability of the randomized number is the shape of normal distribution.

Step5. Improving the intersecting operator. Vehicle dispatching has particular structure, but the chromosome coding in the traditional genetic algorithm adopts the mixed method of single-point, multi-point, and changing to arrange, which destroy the chromosome and excellent substring form, and it can not create the new filial generation if the two chromosomes of the last generation are the same. Thus, we must improve the traditional genetic algorithm. Selecting the location of DC 0 when it intersects coding based on the particularly coded chromosomes, preventing to damage the excellent substring and the last chromosome. Furthermore, the method that makes the substring move to the first place of the chromosome to intersect not only can keep the integrity of the excellent substring, but also can create the newly excellent substring in the case that parents' individual chromosomes are the same, and create the better new substring individual with the help of improved variant operation. Thus improve algorithm's ability to search the excellent individual and the convergent speed. The detailed operating process is as follows:

Firstly, intersect and duplicate the chromosomes. Chose two chromosomes named A and B, whose probability value is 0.85, and then produce two natural numbers between 1 and m , named r_1 and r_2 .In the new algorithm, we require the substring chromosomes in A to be duplicated into the fore-end of the last generation named $B*$,at the same time, we duplicate the substring chromosomes in B into the fore-end of the last generation named $A*$. Next, choose the location of the rest 0 and insert the 0 into the head and end of the next generation's chromosomes named $B*$ and $A*$, and insert the rest 0 of m-2 to the blank space randomly, satisfying the arbitrary 0 having content. Finally, complement the rest genes of the chromosomes, that is to say, fill the different genes of the last generation and next generation into the rest chromosomes, thus create a new individual.

Step6. Improving the varied operation. Selecting a chromosome randomly whose probability is 0.15, and create two natural numbers between 1 and n＋m. If the two groups of genes corresponding nonzero value then it will intersect and create a new individual; if not, it will be going on until the intersecting numbers created. We apply the improved algorithm on chromosomes $0i_4i_50i_3i_1i_20i_7i_6i_80$ to mutate and create a series of new chromosomes named $0i_3i_70i_1i_2i_50i_4i_6i_80$. The detailed process is shown in figure 3.

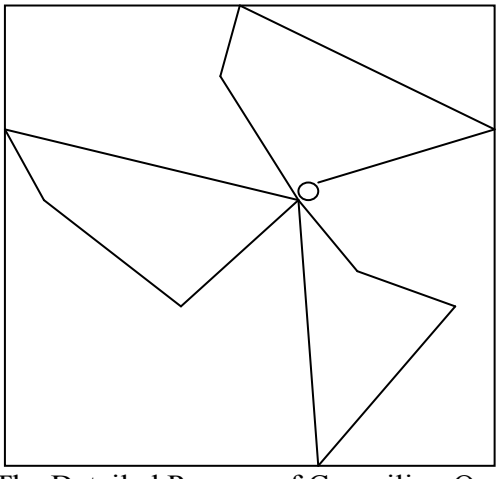

Fig 3.The Detailed Process of Compiling Operation

Step 7: Improving the terminated condition. If we repeatedly create the population biology to five times and we get nothing, then we will stop the algorithm. If it does not satisfy the terminated condition then it will turn back to the original place, or we will adopt step 8.

Step8. Outputting the results. Output and create the individual which has the greatest sufficiency in the population biology, and produce the optimized solution of the issue, realizing the best dispatching scheme of the vehicles.

In order to improve the convergence speed of the whole network of the improved genetic algorithm, we limit the expanding mechanism of the population biology: we improve the genetic algorithm in one way that we take advantage of the individual information, using the method of expanding the population biology in the light of varied sufficiency, we combine the excellent p individuals in the last generation to the p individuals in the contemporary and create a new population biology called 2p,so we finish the expand of the optimized population biology[4]. And then we intersect, rearrangement and mutate in this population biology and get the new generation biology of p individuals.

Keywords: The opportunity network. Routing algorithm. The malicious nodes. Flooding attack .robustness

Abstract. This paper designed the evaluation method and the index system. Through simulating behavior of pedestrian with mobile intelligent Bluetooth devices in the real city scene and did a quantitative analysis about the effects of flooding attacks to opportunity network in the three aspects of transmission capacity, transmission efficiency and energy consumption of nodes , in order to evaluate Direct Delivery, Spray and Wait and MaxProp the three opportunity network routing algorithm's robustness under the flooding attack results showed that Direct Deliven algorithm robustness is best, it can withstand flooding attacks completely, robustness of the Spray and Wait algorithm is the worst, their performance will decline more than 80% in some scenarios, the performance of MaxProp algorithm under flood attacks will decrease remarkably.

Introduction

The opportunity network[1]is a self-organizing network which needs not exist complete path between the source node and the destination node and uses the meeting opportunity by node mobile providing to realize network communication can tolerate delay and splitting , it can be regarded as the wireless self-organizing networks with general DTN features. The opportunity network is different from traditional multi hop wireless network, the path between source and destination nodes can not predetermine whether there is or not.

Opportunity network uses nodes meet opportunisty to realize communication, network node can not be controlled,so it brings more challenges for data confidentiality and integrity, routing security like the traditional network, there may be malicious nodes attempt to attack the network ,delay transmission or destroy data in opportunity network. In the traditional security MANET, through ID authentication to ensure that all nodes in the network are legitimate nodes, each node acts are trustworthy behavior, so as to effectively prevent malicious attacks .But in opportunistic networks, due to its inherent characteristics, encryption and ID authentication are difficult to effectively deploy, in the absence of effective encryption and identity certification, the presence of malicious attack is inevitable.

Based on the above reasons, this paper studied in the absence of encryption and ID authentication, robustness of opportunisty network's typical Routing algorithm under the condition of existing flooding attacks of malicious nodes in the network.

Background and motivation characteristics of the problem

Security is an important research field in opportunistic networks, clear characteristics of the security problem in opportunistic networks and how to ensure data confidentiality and integrity, to ensure the availability of network are concerned problem around researchers presently. The concept of opportunity networks was proposed for a short time, the current study for the opportunity network 's security problem is less, but researches on the security of predecessor opportunity DTN network and mobile ad hoc network have more sufficient, the related researches mainly have:

The literature [2-4] describes respectively threats DTN network facing, mainly have non node threats, resource consumption, DoS attack, confidentiality and integrity, the broadcast storm problem and so on. The literature [5] describes a specific form of attack, mainly have drop attack, flooding, forged ACK, destroy the routing table, send malformed packets, replay, flow analysis, the authorized user listens to other users and so on.

The literature [6] researches loopholes in the mechanism of Epidemic, stated that the routing mechanism under the malicious attack is very difficult to achieve, and the result depends on the specific network scenarios. UMass Dieselnet project by literature [5], quantitative analysis on attack effect under the condition of lack of security mechanism in DTN network, concluded that even in the strong attack, DTN network is still robust.

To sum up, the safe problem in opportunistic networks has not an effective solution, the traditional scheme based on encryption and authentication is difficult to achieve in opportunistic networks. In this case, if we can make an accurate assessment on the routing algorithm's robustness, it is a vital significance to the establishment of safety system efficiently and can reduce the cost of resources overhead on security system, can solve some security problems directly , this is the study motive of the paper.

Opportunity network routing algorithm and the robustness analysis method

Opportunity network routing algorithm. The opportunity network typical routing algorithms contains Direct Delivery, Spray and Wait, MaxProp. The Direct Delivery algorithm bases on the forwarding strategy, in the process of the routing algorithm message transmission, the nodes would not copy the message, only one copy of the message is in transmission; Spray and Wait algorithm bases on flooding strategy, in this kind of routing algorithm, when meet 2 nodes replicate messages to each other, and to avoid excessive flooding by defining a message of life cycle or the number of copy ; MaxProp algorithm bases on the scheduling strategy, the algorithm based on the transmission success rate sets priorities for message, when 2 nodes meet, in accordance with the message priority to determine copy order.

Analysis method. In this paper, by setting a specific scene,it analyzed and compared the performance of many routing algorithms under the flooding attack through software simulation and to evaluate the robustness of routing algorithms.

1) flooding attack

The nodes meet, malicious nodes send false message to any node,this behavior can be such extreme cyber source and to achieve the purpose of blocking legitimate message transmission, in wired network flooding is the basis of Dos attacks, severe flooding can lead to paralysis of the entire network. In opportunistic networks, because there is no always link, malicious flooding behavior is difficult to continue and will obviously affect the flooding effect. In this paper,there is a quantitative measure of flooding attack effect in the opportunity network.

2) measure

From the transmission capacity, transmission efficiency and energy consumption of nodes in the routing algorithm, three aspects to evaluate the robustness of routing algorithm. In order to quantitative comparative analysis, choose the following three indices as metrics.

*a)*Transmission rate (Delivery Ratio) is a message count ratio between target node packets receieve successfully in a certain period of time and source nodes need to transmit , the metric values the capacity that routing algorithm forward the correct message to the target node, it is the most important indicator.When there is a malicious node in this paper, only calculate normal node's transmission success rate.

*b)*Transmission delay (Delivery Delay) is the time that a message from a source node to a destination node required, usually uses the average transmission delay as a evaluation. Although the opportunity network allows large delay, but the short delay means that routing algorithm has strong transmission capacity, high transmission efficiency, but also means that the message will in the transmission process takes less cyber source.

c) Routing overhead (Overhead) refers to the total number of messsage node forwarding in a certain period of time ,overhead rate evaluates it, Namely , a ratio of total message of the all successfully reached destination node and all nodes forwarding the message number.

The simulation experiment based on simulator ONE

The opportunity network simulator. The ONE simulator is a simulation platform of opportunistic networks developed by SINDTN and CATDTN project, provided support by the research centre in Finland Nokia for. ONE is a simulation engine based on discrete events, each step in the simulation engine will update many modules, so as to realize the whole simulation function. It can use different routing protocols to simulate the sending and receiving of DTN messages, and generate the moving track record. ONE simulator function mainly includes the model of node mobility, communication between nodes, routing and message processing, observaion of real-time mobile nodes and message transmission through GUI, the collection and analysis of visualization data etc, and can use the gnuplot tool to show the data graph.

The ONE simulation platform is composed by the simulation engine, event generator, mobility model, routing model, visualization and reporting module etc, figure 1 shows the specific structure of ONE simulator.The opportunity network simulator ONE is an open source simulation platform developed on Java . Each part in a simulator is made up by different packages, as shown in figure 2. The core components of the simulator (such as the host defining DTN and class between host connections) are placed in the core package. GUI related classes are in the GUI package. The GUI package also includes a playfield packet; it defines some class displayed in the playfield view. Basic user interface class and output class based on text are in UI package.

Simulation scenario installment . The text using the ONE simulation platform simulated pedestrians carried with intelligent Bluetooth device walking in the real city scene, and analyzed the robustness of three routing algorithms under the flooding attack. The specific scene installment as shown in Table 1 set.The table 1 shows the scene that it set up a total of 200 normal nodes with no malicious node, the performance of each routing algorithm as shown in table 2. For comparison purposes, data in Table 2 used as the baseline in the following analysis, figure 3 to figure 5 ordinate values are the ratio of specific scene value and baseline scenario corresponding value.

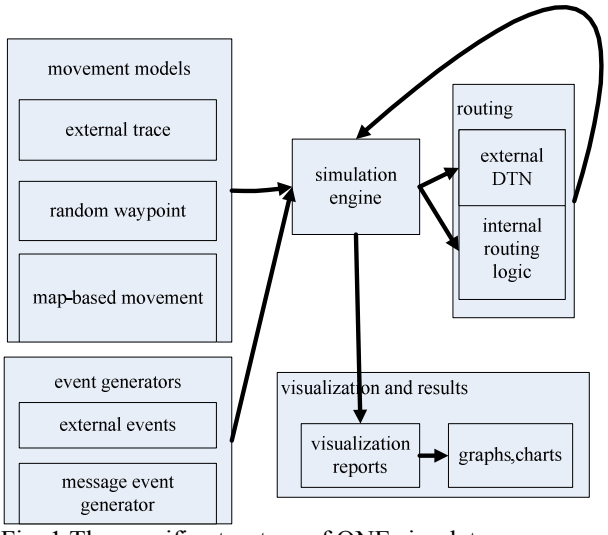

Fig. 1 The specific structure of ONE simulator

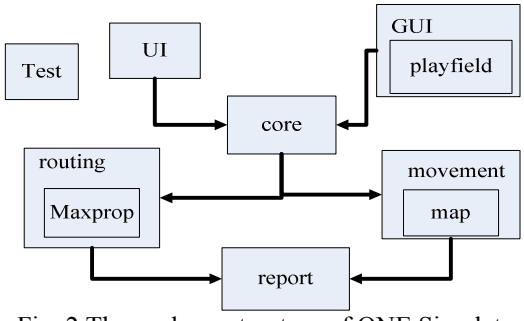

Fig. 2 The package structure of ONE Simulator

For the quantitative analysis of influence of malicious nodes' flooding attacks on the routing algorithm, using table 1 shown scene, it set up a total of 200 nodes and 0 to 100 of malicious nodes. The results of experiment shown in Figure 3 to Figure 5. Under the flooding attack, it has no effect on the Direct Delivery algorithm, the other two algorithms performance decreased significantly, the delivery delayed of Direct Delivery and MaxProp algorithm increased slightly, while the Spray and Wait algorithm significantly decreased. Figure 5 shows the flooding attack will make dramatic

increase in routing overhead of the Spray and Wait algorithm, it have no impact on the Direct Delivery algorithm, the influence on the Maxprop algorithm is a relatively minor.

Table 1 Scene Settings

classes	parameters	value
Scene features	simulated time	12h
	Simulation area	4500m 3400m
	Simulation background city	Helsinki
Node characteristics	movement speed	0.5~1.5m/s
	transmission speed	250kb/s
	Maximum transmission range	10m
	transmission mode	broadcast
	Node cache size	5MB
Characteristics of the message	Packet Size	500~1024kb
	Message survival	5h
	Message generated frequency	25~35s

metric	Direct Delivery	Spray andWait	Maxprop
DeliveryRatio（%）	28.5	50.1	48.0
Delivery Delay	7192	3490	5126
Overhead	0	9.7	149.6

Fig. 3 Delivery Ratio

Fig. 4 Delivery Delay

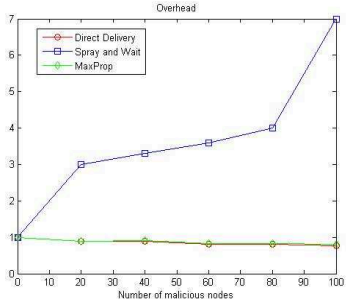

Fig. 5 Overhead

Summary

The experimental results showed that when there are more malicious nodes, except the Direct Delivery algorithm, the other algorithms' transmission success rate dropped sharply. Direct Delivery algorithm has excellent robust, when the attack occurred, 3 indexes of the algorithm almost do not change. The algorithm because of its mechanism of natural can effectively resist flooding attack. While the Spray and Wait algorithm is the most sensitive to flooding attacks, when there are more malicious nodes, transmission success rate will drop 80% above, routing overhead will increase by more than 5 times. If the Direct Delivery and Spray and Wait as a typical representative of routing algorithm based on the forwarding and replication strategies, it would be derived a conclusion in this paper that the routing algorithm robust based on replication strategy is worse than one based on forwarding strategy.

The results also showed that, when there is less malicious nodes , attack is difficult to work, to be successful, it needed malicious nodes with larger proportion, and even successful attack is also difficult to make a complete collapse of, in this view, the opportunity network routing algorithm is quite robust compared with the traditional network.

Key words: UWB; indoor positioning; TOA; S-V model; CHAN algorithm

Abstract. Currently, there is an urgent need for indoor positioning technology. Considering the complexity of indoor environment, this paper proposes a new positioning algorithm (N-CHAN) via the analysis of the error of arrival time positioning (TOA) and the channels of S-V model. It overcomes an obvious shortcoming that the accuracy of traditional CHAN algorithm effected by no-line-of-sight (NLOS). Finally, though MATLAB software simulation, we prove that N-CHAN's superior performance in NLOS in the S-V channel model, which has a positioning accuracy of centimeter-level and can effectively eliminate the influence of NLOS error on positioning accuracy. Moreover, the N-CHAN can effectively improve the positioning accuracy of the system, especially in the conditions of larger NLOS error.

Introduction

With the development of mobile communication wireless sensor network, positioning technology has entered a new phase. The demand for indoor positioning and communication is growing[1]. Experts and scholars in the field of communications proposed many methods to solved the limitations caused by indoor complex environment, such as: indoor GPS positioning, ultrasound positioning, Infrared positioning, Bluetooth positioning, radio positioning, WLAN positioning and ultra-wideband(UWB) positioning[2].UWB systems have many advantages compared to all the others technology such as: strong penetration, confidentiality, low power consumption, high resolution in multipath, ease of integration, positioning performance [3]. In UWB impulse radio positioning method, TOA estimation method can make full use of the advantages of UWB signal having high time resolution to meet accuracy requirements. Generally, the system obtains information by estimating the time delay of TOA UWB multipath signal of the direct path (DP). For line-of-sight (LOS) environment, just to ensure adequate SNR, the system will be able to obtain a more accurate estimate of TOA, because DP is first to arrive and the energy of it is the strongest. Thus it has high positioning accuracy in theory. For non-line-of-sight (NLOS) environment, due to the presence of various obstacles, propagation environment has become complex, DARPA's a NETEX report discusses the UWB pulse propagation characteristics in different media [4], noting that DP will experience obstacles attenuation when penetrating obstructions, and will introduce additional delays, which have greatly influenced TOA performance estimates. Because of NLOS environment, UWB indoor positioning system from the practical application there is a great problem to be solved.

Algorithm Design

The network system of UWB indoor positioning based on TOA shown in Fig.1, it requires that the clock of target synchronize with each UWB detector. The rough working process of the system as follows: the target carries a IR-UWB beacon, and automatically transmitting a periodic pulse signal, the signal produced by the target through the environment of room, received by the UWB detectors in the positioning region , after appropriate treatment the signal is transmitted to the terminal processor, positioning system get the target location by using some algorithms, and displaying it on the terminal.

Assuming the detectors number of UWB positioning system is N, the coordinates of each detector is (x_i, y_i) (i=1,2……N), the location of target is (x, y), the time sending the pulse signal is t ', the time

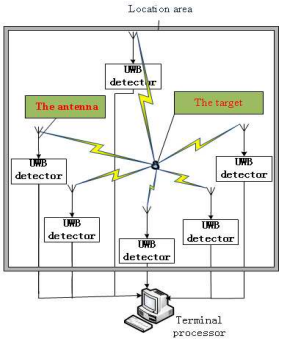

Fig. 1 System Schematic

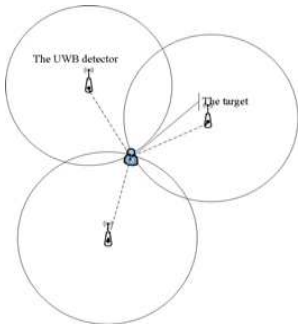

Fig. 2 The positional relationship between the detectors and the target in LOS

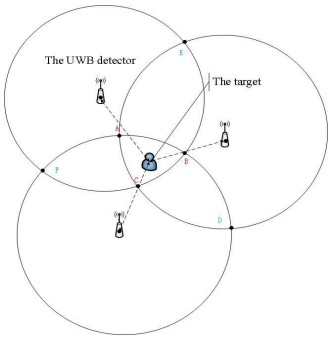

Fig. 3 The positional relationship between the probe and the target in NLOS

of the signal received by each detector is t_i (i=1,2……N), The distance between target detector is d_i:

$$d_i=c(t_i- t') \quad (1)$$

$$(x_i-x)2+(y_i-y)2=d_i^2 \quad (2)$$

If the transmission of signal between the target and the detectors is LOS, the target would be in the intersection point of the circles formed by (x_i, y_i) and d_i. When N=3, the relationship between the target and the detectors shown in Fig. 2.

However, there are many obstacles in indoor environment, specially in cargo warehouses, offices, so the propagation path between the target and detector may be NLOS. When the electromagnetic waves meet obstacles, higher frequency signals often penetrate buildings directly, and the low frequency signals over obstacles by diffraction, it leads to the power of first received signal is weak and the time of UWB detector greater than the real time t_i.

If three detectors are used in this system, the positional relationship between the target and detector as shown in Fig. 3. The target would be in the area D(x,y) which is the area overlapped by three circles. In any of the two circles, if they satisfy the relationship of (3), i.e.the measurement data of R_i has a large error (assuming $R_i>R_j$), then discard the measured value R_i .

$$\left|R_i - R_j\right| > \sqrt{(x_i - x_j)^2+(y_i - y_j)^2} \quad (3)$$

From [5], we know that there are two ways to improve the positioning accuracy: 1, increasing the number of detectors to positioning within the region; 2, determining whether the path between the target and detector is NLOS, if so, try to eliminate the NLOS error. For first way, it would increase costs inevitably if a large number of detectors are used in the system, people are not willing to accept the method. For second way, the cellular mobile communication system has done a lot of research at home and abroad, such as: Kalman filtering, Bayesian methods, maximum likelihood estimation and scattering model approach. In this paper we considered the particularity of UWB indoor propagation, and designed the way to identify and reduce the NLOS error, then, further eliminated NLOS errors and achieve positioning by using the CHAN algorithm.

Channel model is an actual channel transfer function, the received signals can be predicted after channel transmission, which is similar to real environment and play an extremely important role for research. Salen-Valenzula (S-V) model is the most common statistical model which apply in the indoor discrete channel impulse response, the amplitude of receiving component is independent Rayleigh random variables, variance and additional delay in the cluster shows exponentially decay with the delay of cluster. S-V model uses two independent Poisson process to describe the first path to reach the cluster and the reach of multipath relative to it's reach of the first path within the cluster. Specifically, the variables are defined as follows:

Tn: the arrival time of the first path of the n-th cluster;

$\tau_{k,n}$: the delay of the k-the path within the n-th cluster relative to the first path arrival time path, and let $\tau_{1,n} = T_n$;

Λ : Cluster arrival rate;

λ : The arrival rate of path within clusters;

$a_{k,n}$: the multipath gain coefficients;

The UWB indoor channel model can be expressed as:

$$h(t) = \sum_{n=0}^{N} \sum_{k=0}^{K} a_{k,n} \delta(t - T_n - \tau_{k,n}) \tag{4}$$

Make the first multipath cluster arrival time obey the Λ Poisson distribution, other multipath within cluster's arrival time obey the λ Poisson distribution, we can get:

$$\begin{cases} P(T_n | T_{n-1}) = \Lambda \exp\left[-\Lambda (T_n - T_{n-1})\right], n>0 \\ P(\tau_{k,n} | \tau_{k-1,n}) = \lambda \exp\left[-\lambda (\tau_{k,n} - \tau_{k-1,n})\right], k>0 \end{cases} \tag{5}$$

According to the simulation of S-V channel model submitted by 802.15 working group, we can get the waveform of receiving end and the excess delay in LOS and NLOS, as shown in Fig. 4 and Fig. 5. Though Fig. 4, we can get that the amplitude of the DP is maximum under LOS which means it is the strongest path, however, in NLOS, the amplitude of the DP is not the greatest, it appears about 48ns in Fig.5. We can drawn the excess delay under NLOS is much larger than LOS from the comparison between Fig. 4 and Fig. 5. Therefore, whether the measured error of NLOS can be changed into LOS would directly influence the positioning accuracy of the system.

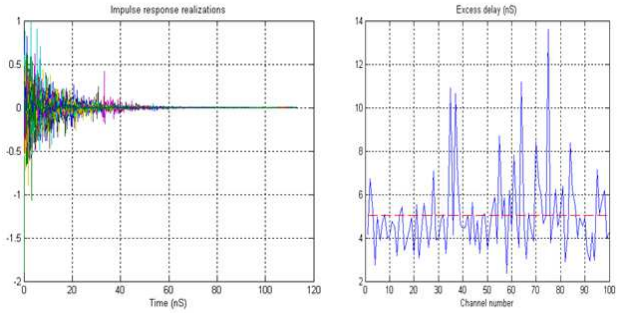

Fig. 4 The pulse signal under LOS

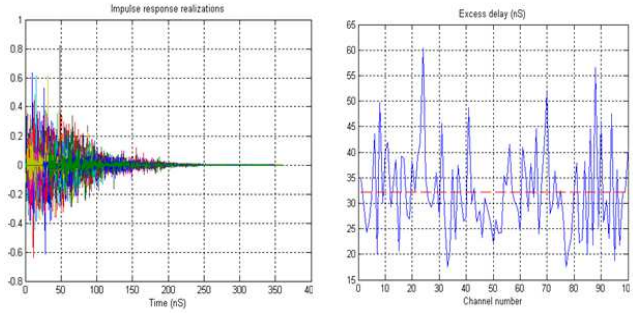

Fig. 5 The pulse signal under NLOS

Since the time interval between two pulses is very short which is usually ns level. We can approximate consider the relative position between the probes and the target is unchanged, and the channel environment is unchanged. If the same detector adopt different transmit power, the strength of the received signal must be different. The paper adopt the UWB single pulse signal of Rayleigh function Pr(t) , which can be expressed as:

$$P_r(t) = A_i \left(\frac{t}{\tau_p}\right) e^{-\left(\frac{t}{\tau_p}\right)^2} \qquad (i=1 \text{ or } 2) \tag{6}$$

A_i is the amplitude of the signal; τ_p is time constant, which decide the single pulse waveform; t is time.When $A_2=1.5*A_1$, Get the pulse waveform, as Fig. 6 shown.

Set the time intervals between each pulse signal is ε , the pulse signal is:

$$p(t) = \begin{cases} P_r(t); 0<t<T \\ 0; T<t<\varepsilon \end{cases} \tag{7}$$

$T>5\tau_p$, if the pulse repetition period is T, we can get:

$$x(t) = \sum_{n=0}^{\infty} p(t - nT) = \begin{cases} \sum_{n=2k+1}^{\infty} A_1 \left(\frac{t}{\tau_p}\right) e^{-\left(\frac{t}{\tau_p}\right)^2} \\ \sum_{n=2k+2}^{\infty} A_2 \left(\frac{t}{\tau_p}\right) e^{-\left(\frac{t}{\tau_p}\right)^2} \end{cases} \quad (k=0,1,2,\ldots) \tag{8}$$

After x(t) though pulse amplitude modulation, we can get the modulated signal $x_{A(t)}$ as follows:

$$x_A(t) = \sum_{n=-\infty}^{\infty} a_n x(t - nT) \tag{9}$$

a_n is the amplitude of the modulation signal. The signal sent by a transmitter antenna, through the indoor channel, then received by a receiver, finally the signal form is:

$$x_d(t) = \sqrt{P_i} x_A(t - \tau_p) + n(t) \tag{10}$$

$\sqrt{P_i}$ is the power of input signal pulse, the received signal first though the low noise amplifier amplifies the signal, then pass matched filtering filter and correlated demodulator. If the first transmit power of the pulse signal is P_1 and the received decision threshold value of the signal is h, which is the maximum amplitude of the the received signal. From (1), (2), we can obtain that the overlapping area D(x, y). The more big the area of D(x, y) indicates the more great measurement error. The second transmit power P_2 ($P_2 > P_1$), the decision threshold:

$$h'=h-k\varepsilon \tag{11}$$

ε is proportional to the area of D(x, y), k is a constant which is related to the positioning environment, but the minimum of h' should be significantly larger than the noise. There are two cases: 1, it is LOS between the target and detectors, since the DP is the strongest path, the second transmit time of the signal detector received is same with the first time, i.e. $t_1=t_2$; 2,when it is NLOS between the target and detector, since the DP is not the strongest, but the second transmit power is greater than the first, and the amplitude of the received signal must greater than the first time and the second threshold is lower than the first time, there will be: $t_2<t_1$, according to (3), we can judge whether there is a large error in the measured value, if so, discard it.

Let: $$\Delta=t_1-t_2 \tag{12}$$

Δ has positive correlation with NLOS error, so if the number of the detector receiving signal at this time is N, and N>3, select three relatively smaller values of Δ in the second measurement to locate.

Then adopting CHAN algorithm to positioning and displaying the location of target on the terminal.

CHAN algorithm using two-step maximum likelihood estimation, the specific process can reference [13]. The algorithm has a small error and it can get Cramer-Rao Lower Bound (CRLB) in the case of a enough small error of measurement parameters. It has a high positioning accuracy compared to other TOA/TDOA algorithm in Gaussian noise environment, but the positioning accuracy would decrease quickly in the NLOS environment. We can get the following relations when set the first detector as reference:

$$\Delta R_i^2+2\Delta R_i R_1=K_i-K_1-2\Delta x_i x-2\Delta y_i y \tag{13}$$

In (13): $\Delta R_i=R_i-R_1$, $K_i=x_i^2+y_i^2$, $\Delta x_i=x_i-x_1$, $\Delta y_i=y_i-y_1$

When i=1,2,3. We can be obtained (14) from (13):

$$\begin{cases} x=p_1+q_1 d_1 \\ y=p_2+q_2 d_1 \end{cases} \tag{14}$$

$$p_1=\frac{\Delta y_3\Delta R_2^2-\Delta y_2\Delta R_3^2+\Delta y_3(K_1-K_2)-\Delta y_2(K_1-K_3)}{2(\Delta x_3\Delta y_2-\Delta x_2\Delta y_3)} \tag{15}$$

$$q_1=\frac{\Delta y_3\Delta R_2-\Delta y_2\Delta R_3}{\Delta x_3\Delta y_2-\Delta x_2\Delta y_3} \tag{16}$$

$$p_2=\frac{\Delta x_3\Delta R_2^2-\Delta x_2\Delta R_3^2+\Delta x_3(K_1-K_2)-\Delta x_2(K_1-K_3)}{2(\Delta y_3\Delta x_2-\Delta y_2\Delta x_3)} \tag{17}$$

$$q_2=\frac{\Delta x_3\Delta R_2-\Delta x_2\Delta R_3}{\Delta y_3\Delta x_2-\Delta y_2\Delta x_3} \tag{18}$$

Bring (14), (15), (16), (17), (18) into (2), and make i=1, we can get:

$$ad_1^2+bd_1+c=0 \tag{19}$$

In (19), $a=q_1^2+q_2^2-1$, $b=-2\left[q_1(x_1-p_1)+q_2(y_1-p_2)\right]$ $c=(x_1-p_1)^2+(y_1-p_2)^2$. We can get two roots d_{11}, d_{22} of d_1 from (19), and they have the relationship: $d_{11}<0<d_{22}$, discard the negative root d_{11} and bring the effective root d_{22} into the equal(14), we can get the estimated position of the target.

Simulation

Assuming 6 detectors randomly distribute on a two-dimensional (2D) plane, the detector coordinates are: (0, 0), (0.66, 12.2), (8.66, 5), (12, 16.5), (13.5, 2.5), (17.2, 10.5). The measured

target location coordinate is (8, 6), using the CM3 channel of S-V, $P_2=2*P_1$, k=1, $\varepsilon=0.2\cdot S_{D(x,y)}$. The simulation results are shown in Fig. 7. CHAN-Taylor which is a joint positioning algorithm using the result of CHAN algorithm positioning as the Taylor initial positioning. Easily obtained from Fig. 7 that: N-CHAN algorithm positioning accuracy is significantly higher than CHAN-Taylor algorithm and CHAN algorithm; the positioning error of N-CHAN algorithm between positioning result and target is very small.

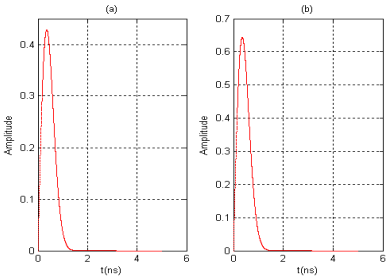

Fig. 6 The comparison chart of different amplitude of the pulse signal

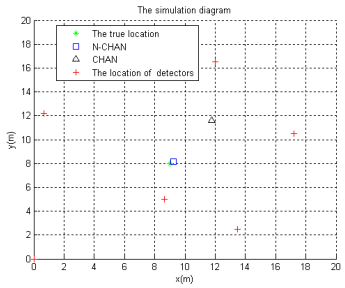

Fig.7 2D Simulation Figure

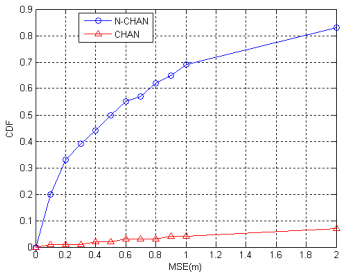

Fig.8 MSE and CDF's Relationship

Distributing the target in the area of 20m * 20m randomly, the introduced function of TDOA distance error is: e=randn(100,100)+3 (m). 1000 times positioning experiments are carried out, we get the relationship between CDF and the mean square error (MSE), as shown in Fig. 8. From Fig. 8, we can get: the traditional CHAN algorithm is not suitable for positioning under NLOS, and the improved N-CHAN algorithm has a high positioning accuracy, About 70% of positioning results'MSE for N-CHAN is less than 1m, which would make it possible for us to locate using the CHAN algorithm in larger NLOS.

Conclusion

In this paper, we proposed a method to decrease the NLOS error by analyzing geometry of TOA positioning and the channel model of S-V, which could reduce the overlapping geometry area so as to reduce the positioning error. Finally, we simulated the N-CHAN algorithm in the 2D plane, the results showed that this algorithm can satisfy the requirements of indoor positioning and eliminate the NLOS error, the position accuracy of it can reach cm level besides. But whether can get a proper function to describe the relation between the overlapping area and the threshold values (k and λ) which were proposed in this paper would have a significant effect on the positioning results, it needs take amounts of practice and statistical analysis subsequently.

Keywords: SDH communication network; the confidence fusion algorithm; alarm association rules mining

Abstract: In this article we achieve SDH communication network correlation analysis by the confidence fusion algorithm. We take the effect of the alarm topology relationship on the alarm timing relationship into the calculation process of confidence fusion algorithm .Thus it can get alarm correlation results more in line with objective facts. According to the correlation calculation results it forms the alarm correlation transactions, then applying the alarm correlation transactions to the alarm association rules mining. We compare the mining results with the traditional method based on sliding window. The experimental results show that the mining results are more effective after introducing the confidence fusion algorithm.

Introduction

WINEPI algorithm[1] is an alarm association rule mining algorithm widely applied to alarm association rules mining, the basic idea is to use a sliding time window to get alarm transaction ,then it generates stronger alarm association rules in accordance with high support – high confidence theory. The key issue is to set the size of the sliding time window and select the appropriate support and confidence threshold. However, the statistic of the occurrence of the alarm items during each time got from one actual communication network showed that the occurring time of alarms is random. Implementing a unified time window for the whole network alarm has the following problems: If the window is selected too small, the relevant alarm information will be lost; if the window is selected too large, it will introduce false rules and irrelevant data. The traditional association rules are based on high alert support - high degree of confidence. In practical engineering, some alarm association rules with high degree of confidence that occur less frequently, are also of practical significance.

To solve the above problems, this paper presents an alarm association rules mining algorithm based on the confidence fusion algorithm. The algorithm uses the alarm time properties and network topology to achieve confidence integration with multi evidences. Then, according to the value of confidence integration it generates alarm transactions. The article also combined FP-Growth algorithm and confidence theory to quickly filter out the meaningful association rules, remove false alarms, thus achieving an efficient algorithm for mining association rules.

1 An alarm Association Rule Mining Algorithm

1.1 Algorithm input

Source alarm history database RD, the confidence threshold $\min_C$, support threshold $\min_S$, the relevant time TR_1 TR_2,the network topology matrix NT

1.2 Algorithm output

Alarm transaction base TD and the alarm association rule base ACR.

1.3The main steps of the algorithm:

Definition 1 In order to characterize the relationship between the two alarms, define a quintuple $AR = (A_i, A_j, TI, NT, R)$, i and j are positive integers. A_i, A_j represent two adjacent alarm items; TI represents the absolute value of the time interval of two alarm items; NT indicates that the network topology of two alarms, if two alarms are generated in the same station, $NT = 1$; if two alarms are

generated in two adjacent stations, $NT=2$; otherwise $NT=3$. R represents of the value of the integrated correlation of two alarm items.

1.3.1 Calculating the comprehensive correlative degree of two adjacent alarms

①,Judge the value of TI ,If TI is greater than TR_2, $R=0$;if TI is less than TR_1, $R=1$; else execute ②.

② Judge NT , if $NT=3$, $R=0$;otherwise execute③..

③ According to the formula (1-3) to calculate the value of R , if $R>=0.9$, then $R=1$,else $R=0$.

1.3.2 The flow of generating alarm transactions

① $i=1, n=1$

②Judge whether reaching to the end of the history alarm database. If so, end; otherwise, determine the value of R of A_i and A_{i+1} ,if $R=1$, then put two A_i and A_{i+1} into one alarm transaction AT_n , $i=i+1$ .otherwise execute ③.

③ $n=n+1$, Generate a new transaction AT_n , A_{i+1} will be the first item of AT_n , $i=i+1$,execute ②.

1.3.3 Mining the frequent alarm sequences

Apply FP-Growth algorithm[1] to mine the frequent alarm sequences. The details can be seen in [1].

1.3.4 Gaining strong alarm association rules

Calculate the confidence of the frequent alarm sequences, find out the frequent alarm sequence whose confidence is greater than $\min_C$. Define these alarm sequence as strong alarm association rules.

2 Algorithm Key Issues

2.1 Confidence Model Framework

The confidence theory is used to manage the rules uncertainty. This article take the effect of the alarm topology relationship on the alarm timing relationship into the calculation process of confidence fusion algorithm .Thus it can get alarm correlation results more in line with objective facts. The proposed method can effectively alleviate the dependence of the choice of the sliding window.

Definition 2 Based on the confidence model theory , the integrated correlation degree of two adjacent items alarm defined as follows:

$$CF(A_i,A_j)=\begin{cases} CF_1 & CF_1=1 \text{ or } CF_2=0 \\ CF_1+CF_2(1-CF_1) & 0<CF_1<1, CF_2>0 \\ \dfrac{CF_1+CF_2}{1-\min(|CF_1|,|CF_2|)} & 0<CF_1<1, CF_2<0 \\ CF_2 & 0<CF_1<1, CF_2=0 \end{cases} \tag{1}$$

The value of CF_1 is determined by TI .

$$CF_1=\begin{cases} 1 & 0\le TI\le TR_1 \\ \dfrac{TR_1}{TI} & TR_1\le TI<TR_2 \\ 0 & TI\ge TR_2 \end{cases} \tag{2}$$

TR_1 is the minimum value of the relevant time, TR_2 is the maximum value of the relevant time.

CF_2 is determined by the topology of the two alarm items.

$$CF_2=\begin{cases} -0.5 & NT=1 \\ 0.5 & NT=2 \\ 0 & NT=3 \end{cases} \tag{3}$$

3 Experiments

In order to validate the feasibility and effectiveness of the proposed method, we choose one power communication network alarm library as an example, to carry out alarm association rule mining. The actual communication network is based on SDH technology. The SDH transmission network consists of 213 stations, each station is set with a SDH equipment. The alarm library includes 19,992 alarms. The experiment is implemented in the PC configured with i3 3.30GHzCPU, 4.00GB memory, Windows 8.0.

(1) We compared the executing time of the traditional method and the proposed method .The traditional method is based on sliding window. The sliding windows are set as 180s, 300s, 500s, 660s,the sliding steps are set as 90s, 150s, 250s, 330s correspondingly. For the proposed methods, TR_1 are set as 180s, 300s, 500s, 660s, TR_2 are set as 360s, 590s, 978s, 1320s correspondingly. The results are shown in Figure 1.

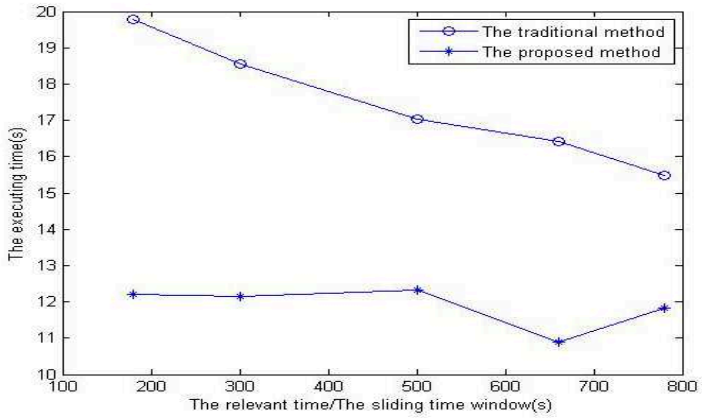

Figure 1 The comparison of the executing time

As showed in Figure 1, for the traditional method ,when the time sliding window becomes large , the executing time of the program becomes small. That is because when the time sliding window becomes larger, the number of generating new alarm transaction gets less, then the executing time gets shorter. But with the relevant time becoming larger for the proposed methods, the executing time does not change monotonously .That is because the number of the alarm items of one alarm transaction is not only determined by the relevant time.

(2) We compare the number of the frequent alarm sequences ,the number of the strong alarm association rules, the number of weak association rules got from the traditional methods and the proposed method .The results are shown in Table 1 . The minimum support count is set as 20, $\min_C$ is set as 50%. The results show that for the same alarm history database, the traditional approach based on a sliding time window can get a larger number of frequent alarm sequences, but also introduces a certain amount of weak association rules . That is, although the proposed methods get less frequent alarm sequences ,the number of strong alarm associations is larger, and the number of the weak association rules is also less. That means, the proposed method can get more meaningful information with less useless information.

Table 1 The mining results of the two methods

	The number of the frequent alarm sequences	The number of the strong alarm association rules	The number of weak association rules
The traditional methods	237	161	76
The proposed methods	180	159	21

Summary

This article firstly introduced confidence fusion algorithm to calculate integrated alarm correlation degree, then generate alarm transactions according to the calculated results., thus alleviating the dependence on the choice of the sliding window .Through the experiments, we know the proposed method can gain more significant information with introduction of less irrelevant information compared with the alarm association rule mining based on sliding time widow.

Keywords: collaborative filtering, purchase prediction, users' behavior.

Abstract. For a more accurate prediction of the probability of consumers to purchase a commodity, this paper build a users' behavior model based on correlation analysis with apriori algorithm. The model is built by learning from users' history data and behaviors' at present, an experimental result demonstrates that this model can effectively predict consumer buying behavior, and it is better than some traditional methods.

Introduction

It can be predicted more accurate about whether the consumers to buy the brand, for the rapid development of the electronic commerce websites. Basket analysis, genetic algorithm, classification tree, hybrid algorithm and so on, are widely applied in the field of customer behavior prediction. Among them, based on the thought of Lin and Mclean in 2001[1], Jinfeng Yao, Chunxu Wu proposed an algorithm, this paper proposes a new model, this model combines three methods: decision tree (DT), artificial neural network (NN), Logistic regression (LR), and they also do the experiment [2], however, the experimental time complexity is too high, and the prediction accuracy is also not so good.

Jen and Wang (1998) simulate the customer purchase in an exponential distribution and gamma model [3], but as a result of multivariate Bayesian model is derived and calculated process is complex, the model only analysis buying interval with univariate, don't mention the customer purchasing behavior. Now, however, the electronic businesses in order to stock up, need to quickly and accurately predict whether consumers will buy the commodity more and more, and the existing research rarely predict customer purchasing behavior. So, this paper applies user behavior to the Apriori algorithm to extract the association rules, and will generate strong association rules applied to score model is set up, and then according to the model to simulate the user behavior score, at last, through the improved collaborative filtering algorithm. The experimental results show the applicability and accuracy are slightly better than the existing prediction methods.

Traditional recommendation systems suggest relevant content to users based on their previous choices. Traditional collaborative filtering recommendation algorithm is based on the assumption, that if a user for some projects is the score is similar, they are more similar to score on other projects.This paper is based on this, puts forward a kind of collaborative filtering algorithm based on user behavior, think: if a customer when buying some merchandise to the behavior is similar to that of their behavior when buying other products is also similar.

The collaborative filtering algorithm based on user behavior

1.The selection of user behavior

There are many user behavior, so we can improve the accuracy of recommendation by selection of appropriate user behavioral characteristics. This paper focuses on customer behavior analysis in the electronic commerce websites, therefore, the consumers behavior can be divided into: browsing, collection, shopping cart, purchase, respectively represented by A, B, C, D.

Browsing, before decide to buy, the customer is bound to be on brand thorough understanding and comparison, so the number of click affected the customer final decision to a large extent.

Collection, shopping cart, we can found that less than one thousandth of the customer is used to collect and shopping cart before purchase through the analysis of the data, therefore, in this article, browsing default for collection and shopping cart.

Purchase, due to the second or multiple purchases will completely depends on the user's needs or satisfaction to the brand, and the correlation to consumer behavior is not big, based on this, we main forces on the first purchase.

2. Data preprocessing

This paper analyze the raw data with the Apriori algorithm, association rules is put forward, to get confidence P (D | A), P (D | B), P (D | C), as weight value, A, B, C, D respectively estimate the score 0.5,2,3,1, all behavior score multiplied by the corresponding weight value, and then together, the final score is the consumer to the brand's score.

Due to some users have too little or too much behaviour before purchase, these are not conducive to the construction of user behavior score, so we delete it, only keep the brands which score are between 2-7 brand [4].

if the customer hadn't buy the goods after browsing , calculation method is also like that. Set r_{ij} as the score that consumer i for brand j, for any brand j, the score $R_{i,j}$ for customer i in the user rating data matrix A (m, n).

$$R_{i,j}=\begin{cases} r_{i,\mathrm{j}}, \text{if user i rated item j} \\ r_{i,\mathrm{j}}, \textit{if user i not rated j} \end{cases}$$

Compared with the cosine similarity measurement and correction of cosine similarity metric method, the customer brand default score is 0, if there's not score ratings for the consumer i to the brand j. for any brand j, the score for the customer i as follows:

$$R_{i,j}=\begin{cases} r_{i,\mathrm{j}}, \text{if user i rated item j} \\ 0, \textit{if user i not rated j} \end{cases}$$

The advantage of that is can be effectively improved the credibility of clients under the extreme condition that score data are sparse, in fact, the user's intention of buy the brand may not be the same, through the behavior to simulate their willingness to purchase, can effectively measure the intention of the customer.

3. The calculation of similarity between users

With the rapid development of the electronic commerce websites, although this exponential growth in the number of customes and brand, the user rating data are extremely sparse, in a large e-commerce website, the brand which user had rated not more than 1% of the total brand in the general[5], the brand which been scored by two useres are less. Based on $I_{i,j}=I_i \bigcap I_j$ (The variable I_A represents all score of the customer A), it is concluded that the accuracy of the similarity between the user is very low, so in order to effectively solve the extreme condition, the problems existing in the traditional similarity measure methods, this paper when calculating the similarity between customer i and j, first calculate[6]:

$$U_{i,j}=I_i \bigcup I_j$$

Then predict the brand score which customer i had not score in collection U_{ij}, the variable N_i represents the project set that user i had not scored brand in set U_{ij}:

$$N_i=U_{i,j}-I_j$$

For any brand $p \in N_i$, the mean score p_{ij} of customers i had purchased as the score of brand p. The variable r_{iavr} represents mean score of the customer i. So, for any brand $p \in U_{i,j}$:

$$R_{i,p}=\begin{cases} r_{i,p}, \text{if user i rated item } p \\ r_{iavr,p}, \textit{if user i not rated } p \end{cases}$$

Then based on the brand collection $U_{i,j}$, calculate similarity between customer i and j with the Cosine Similarity:

$$sim(\mathrm{i,j}) = \cos\theta = \frac{\vec{i} * \vec{j}}{\|i\| * \|j\|}$$

Or adjusted cosine (The variable I_{ij} represents the set which been scored by user i and j, the variable $\overline{R_i}$ represents the mean score of consumer i, the variable $\mathrm{R}_{i,c}$ represents the score of brand c which belong user i, the variable $sim(\mathrm{i,j})$ represents the similarity between consumer i and j.) :

$$sim(\mathrm{i,j}) = \frac{\sum_{c \in I_{ij}} (\mathrm{R}_{i,c} - \overline{R_i})(\mathrm{R}_{j,c} - \overline{R_j})}{\sqrt{\sum_{c \in I_{ij}} (\mathrm{R}_{i,c} - \overline{R_i})^2} \sqrt{\sum_{c \in I_{ij}} (R_{j,c} - \overline{R_j})^2}}$$

Finally, for each user u, find the user set $C = \{C_1, C_2, C_{3,} \cdots C_k\}$ in the entire collection, the similarity of u: $sim(\mathrm{u}, \mathrm{C}_1)$ is the most, then $sim(\mathrm{u}, \mathrm{C}_2)$, $sim(\mathrm{u}, \mathrm{C}_3)$ …

4. The brand of similarity between calculation and prediction results

After get C = {C1,C2,C3,……Ck}, we need calculate the predicted brand similarity between the customer u and the nearest neighbor , according to the similarity measure method. Set $a \in u$ (a is a brand of user u), and $u \in C$. C_{k_a} is a brand of consumer C_k, calculate the $sim(\mathrm{u}_a, \mathrm{C}_{k_a})$, then we can get $sim_{avr} = (\mathrm{sim}(\mathrm{u}, \mathrm{C}_k) + sim(\mathrm{u}_a, \mathrm{C}_{k_a}))/2$, then the highest sim_{avr} as the final result.

5. Purchase prediction based on collaborative filtering algorithm

Finally, set variable R_A represents the mean score of the customer A, variable $\mathrm{P}_{u,i}$ represents the predicted score of the brand i which belong customer u, n is the number of consumers. According to follow recommendation algorithm to produce recommendations, the smaller the value, and then the bigger the probability of purchase. When $\mathrm{P}_{u,i} > 1.5R_i$, we consider the brand will not be purchased.

$$\mathrm{P}_{u,i} = R_u + \frac{\sum_{a=1}^{n} (\mathrm{R}_{a,i} - \mathrm{R}_a) \times \mathrm{sim}(\mathrm{u,a})}{\sum_{a=1}^{n} |sim(\mathrm{u,a})|}$$

The performance evaluation

In this paper , the data sets from a real electronic commerce websites, data time from April 2014 to May 2014, select four behaviours : browsing , collection, shopping cart, purchase. The format as below:

Table 1 Data Format

User_id	Brand_id	type	Visit_datetime
10944750	13451	0.5	6.4
10944750	13451	0.5	6.4
10944750	13451	0.5	6.4
10944750	13451	0.5	6.7
10944750	1182	0.5	6.7
10944750	1182	2	6.7
10944750	1182	1	6.7

Because this article comparative object is the hybrid algorithm which mentioned by Jinfeng Yao, Chunxu Wu (this algorithm include three methods: decision tree (DT), Logistic regression (LB), artificial neural network (NN).). So we take the same test standard: error probability. the final error probability in the training set and test set is shown in the figure below:

Table 2 Final Result

Algorithm	Error probability 1	Error probability 2
Collaborative filtering	N/A	0.112
Hybrid	N/A	0.113
DT	0.109	0.124
NN	0.115	0.132
LB	0.108	0.139

Thus it is not hard to see, purchasing behavior prediction which based on collaborative filtering algorithm with better accuracy, this method provides a more reliable basis for managers to decide further market strategy, at the same time, the probability of purchase can help enterprise managers to lock the potential customer base, to guide customers which purchase rate is higher in real-time, as far as possible translated potential customers into real customers.

Summary

Customer behavior prediction as an important branch of Web log mining, has not yet formed a mature theory and technology, this paper puts forward the purchasing behavior prediction that based on collaborative filtering algorithm, is an effective, more accurate forecasting method, but because of the data preprocessing methods is a wide variety, so the similarity between users can make a big difference, therefore, the next step of research work will further improve the data pretreatment, and consider the transfer of user interests over time.

K-means Clustering Algorithm Method Based on Shuffled Frog Leaping Algorithm

Tang Zhe[a], Luo Ke[b]

Changsha University of Sciences and Technology, Changsha 410114, China;

[a]295413610@qq.com, [b]luok@csust.edu.cn.

Keywords: cluster;genetic algorithm;ant colony optimization algorithm;shuffled frog-leaping algorithm;K-means.

Abstract. Aiming to resolve the problems of the traditional k-means clustering algorithm such as random selecting of initial clustering centers,the low efficiency of clustering,low in the real,this paper proposed a novel k-means clustering algorithm method based on shuffled frog leaping algorithm.This algorithm combined the advantages of k-means algorithm and shunffled forg leaping algorithm.A chaotic local search was introduced to improve the quality of the initial individual，a new searching strategy was presented to update frog position,that increased the optimization ability of algorithm.According to the variation of the frog’s finess variance used k-means algorithm,it has the advantages in the global search ability and convergence speed.The experimental results show that this algorithm has higher accuracy..

Introduction

Data mining is the process of concentrated extract valuable information from large amounts of data.Because of the usefulness of data mining, its research more in depth.Cluster analysis is an important data mining analysis tool that has been used in various fields.Cluster analysis of is divided the data into a plurality of object classes or clusters, so that the same class of objects with a higher degree of similarity, as different classe of objects with a lower degree of similarity , distance is used to measure the similarity.K-means[1] clustering analysis algorithm is a classical algorithm, it has a simple, good local convergence performance characteristics, widely used in the field of data mining and knowledge discovery.However, the algorithm selected vulnerable to the impact of the initial cluster centers, appear low clustering efficiency, lower clustering accuracy problems.

Therefore, many scholars have studied from different directions on the algorithm.Such as the introduction of genetic algorithms[2,3],particle swarm optimization [4],ant colony optimization[5] algorithm and other optimization techniques.However, because the algorithm produces degradation in the evolutionary process, resulting in multiple iterations algorithm, clustering and low accuracy problem, and when the object is large-scale clusters, these algorithms may appear to be trapped in local optima premature convergence.

Intelligent search algorithm SFLA[6,7,8] is generated by a frog foraging inspired.SFLA has local search capability of PSO algorithm and global search capability of genetic algorithm optimization.SFLA has the advantage of a simple principle, calculation speed, easy to combine with other algorithms, etc.,it has been used in many fields of natural sciences and engineering sciences.Aiming at the shortcomings of K-means algorithm, this paper proposes a new algorithm that combines SFLA and k-means algorithm . It uses leapfrog algorithm to optimize the initial solution,in order to getting high efficiency of solving.SFLA algorithm generates excellent new individual fitness through mutation, then these fine individuals carry on k-means clustering operation.It has a lot of good results such as optimization clustering effect and improve efficiency of the algorithm, reducing the number of iterations of the algorithm,increases the accuracy of clustering.

Preliminaries

K-means algorithm Introduction. k-means clustering algorithm basic strategy is as follows: Arbitrary find a cluster center for each cluster,determine m cluster centers $\{a_1, a_2, ..., a_m\}$ for n data objects. According to the minimum distance principle,other data objects are assigned to the corresponding clustering. Then,on the basis of $C_i^{'} = \frac{1}{|C_i|}\sum_{x \in C_i} x$,update cluster centers, $|C_i|$ is the number of objects in the i-th cluster. In accordance with the principle of minimum distance, each data object will be allocated to the corresponding cluster, update the cluster center, this process is repeated until no more cluster centers change occurs.

Shuffled frog leaping algorithm.SFLA is a group of intelligent search methods inspired by foraging frogs produced. SFLA similar genetic algorithm, each frog representation of a solution, the frog population is a solution set. The entire population contains many sub-groups,subgroups of the frog has its own characteristics, each subgroup has a unique local search strategies. After all subgroups local search, and you will be the exchange of information between subgroups and achieve global search.

Local search and global search will loop until the end condition is satisfied. Because combining global search with local search,the algorithm can jump local optimal direction towards the global optimum.

Local search is different in each subgroup,it is in order to making each subgroup to search in a different direction. When the local search performed many times,the local optima of subgroup will be very close to the global optimum of the entire group. The best individual fitness frog in subgroups represented by $X_b(t)$,the worst individual fitness frog in subgroups represented by $X_w(t)$,The best individual fitness frog in the entire population represented by $X_g(t)$ .The following operations on $X_w(t)$:

$$D(t) = w_1 \times D(t-1) + c_1 \times rand \times (X_b - X_w) + c_2 \times rand \times (X_g - X_w) \quad (1)$$

$$X_w(t+1) = w_2 \times X_w(t) + D(t)\left(-D_{\max} \le D(t) \le D_{\max}\right) \quad (2)$$

Among them, $c_1 = c_2 = 0.5$,the rand is a random number between 0-1, w_1 and w_2 is the factor of controlling frog search. The values of w_1 and w_2 more bigger more conducive to search globally optimal solution; The values of w_1 and w_2 more smaller more conducive to search local optima solution.

$$w_1 = w_2 = w_{\max} - i_{iter}(w_{\max} - w_{\min}) / i_{mem} \quad (3)$$

$w_{\min}$ and $w_{\max}$ represents the initial weights and the final weights, i_{iter} indicates the current iteration, i_{mem} represents the maximum number of iterations in a subgroup.

Algorithm Design

Encoding and fitness function. Using Encoding mode based on the cluster center,we has the advantage of reducing the time calculations and improving the efficiency of the algorithm. Arbitrary frog X_i expressed as:

$$X_i = (Z_{i1}, ..., Z_{i2}, ..., Z_{im}) \quad (4)$$

Among them, $Z_{i1}, ..., Z_{ij}, ..., Z_{im}$ is a set of cluster centers. When the cluster centers determined,it divide the data set by the nearest neighbor principle.

Fitness function is expressed as:

$$f\left(X_i\right)=\frac{\sum_{j=1}^{m}\left[\sum_{\forall D_p\in C_{ij}}\frac{d\left(D_p,Z_{ij}\right)}{\left|C_{ij}\right|}\right]}{m} \tag{5}$$

Among them, $d\left(D_p,Z_{ij}\right)$ represents the Euclidean distance between D_p and Z_{ij}. $\left|C_{ij}\right|$ represents the number of elements in the cluster C_{ij} .Fitness function value of $f\left(X_i\right)$ is more smaller the effect of the cluster more better, otherwise the worse.

The number of frog populations is n, f_{avg} represents the average fitness of the entire population, f_i represents the fitness of the i-th frog, Group fitness variance[9] is calculated as:

$$\sigma_2=\sum_{i=1}^{n}\left(\frac{f_i-f_{avg}}{f}\right)^2 \tag{6}$$

f is the inertia factor used to limit the size of σ^2:

$$f=\begin{cases}\max\left\{\left|f_i-f_{avg}\right|\right\} & \max\left\{\left|f_i-f_{avg}\right|\right\}\geq 1\\ 1 & otherwise\end{cases} \tag{7}$$

σ^2 is used to determine whether the operation standard k-means. When σ^2 is greater than a certain value, adding k-means algorithm for local search, improve the convergence speed, but also increase the accuracy of the solution.

Initial population. Random initial population with stable populations does not conducive to search, and the use of Tent mapping operator generated initial population has better robustness, help to improve the population's stability and accuracy of the algorithm. The mathematical expressions of Tent mappin operator [10,11]expressed as:

$$x_{k+1}=\begin{cases}2x_k & 0\leq x_k\leq 0.6\\ 2\left(1-x_k\right) & 0.5<x_k\leq 1\end{cases} \tag{8}$$

X represents a variable dimension frog individual, using the formula (7) can be produced N frog from a frog.

$$x_{ik}=a+cx_{ik}\left(b-a\right) \tag{9}$$

(a, b) indicates the vale range of frogs dimensional variables, the effect of equation (8) is carrier each dimension of the variable of the frog individual to the range of (a, b) up.

Initialization frog populations: Randomly generate a self-X, the range of variables for each dimension of this individual is (0,1). The use of formula (7) to generate N individuals $X_j\left(j=1,2,...,N\right)$. Using the formula (8) to carry each dimension of X_j to the range up of optimization variables, produce N within the scope of the initial optimization of individual CX_j, and in accordance with the formula (4) to calculate the fitness function values, the better performance is selected as an initial individual of SFLA.

Generate new individuals Frog: Tent mapping operator is used to randomly generate a Vector X that has the same dimensions with frog. According to the equation (9) for updating the :

$$X'_w=X_w+N\left(0,1\right)\times X \tag{10}$$

X'_w represents the updated instance of the frog, N(0,1) represents the standard normal distribution.

Algorithm Description.Input: The number of subgroups: m. The number of subgroups frog:n. The number of searcher in subgroups: i_{mem}. The number of global search: i_{glo}. The number of operations

performed K-means frog: p_m . Maximum change in position: $D_{\max}$. Final weights: $w_{\min}$. Initial weights: $w_{\max}$. Fitness variance population threshold: θ .

Output: k clustering centers and optimal clustering.

Step 1 Initialization frog. According to 2.2,produce F frogs individual, $F = m \times n$.

Step 2 Divided into sub-groups. Sorted according to the size of the fitness value of frogs. Allocated frog to each sub-group.

Step 3 Frog evolution.

a)According to formula (1) (2) to update poorest adaptation frog of each subgroup. If the updated frog improving effect is not achieved,X instead of B,then following formula (1) (2) Update. Otherwise, according to the equation (9) to generate a new frog instead of it.

b) i_{mem} times to perform steps a), have evolved subgroups.

c)After subgroup evolution is complete, the frogs have evolved subgroup remix, instead of the original populations have evolved frog populations. Global iterations +1.

d)Group fitness variance is calculated according to equation (5). If group fitness variance D is less than the threshold value B,choosing C optimal frogs to K-means operating. Otherwise transferred to step 2.

Step 4 k-means operation

According to the clustering center of each frog and the proximity rule, identify each frog corresponding cluster division.The new center is calculated according to k-means clustering algorithm to replace the original coded.Determine whether the termination condition (maximum number of iterations or a good enough position), calculating the new cluster fitness center, if better than the original frog, updae the frog and end the algorithm, otherwise transfer step 2.

Time complexity analysis. In step 1,the time complexity is $T = O(F \times k)$. In step 2,the time complexity of sort fitness value is $T = O(F^2)$ .In step 3, The time complexity of the evolution and mixing of the frog is $T = o(i_{mem} \times i_{glo} \times F^2)$ .In step 4, The time complexity of the operation performed for the k-means is $T = O(P_m \times F \times k)$;Because $F \gg i_{mem}$, $F \gg i_{glo}$, $F \gg P_m$, so the time complexity of the algorithm can be expressed as $T = O(F^2)$.

Simulation

Algorithm simulation.Software: Operating system windows 7, compiler software Matlab7.0.1; hardware: Intel(R) Core (TM)i3-3240 CPU @ 3.40GHz, memory 2GB.

The data sets in this paper is selected in the UCI: Iris data sets, Wine data sets, Balance-scale data sets, Housing data sets.

Table 1 Compares the parameters for each data set

data sets	Iris	Wine	Balance-scale	Housing
Number of clusters	3	3	5	3
The number of samples	150	178	625	506
Dimension	4	13	4	14

The following were used PSO-Kmeans algorithm, K-means algorithm, K-medoids algorithm and the SFLA-k-means algorithm for clustering analysis of four kinds of data sets, each algorithm is run 10 times to calculate the average value, comparing their accuracy rate.

Table 2 Compares the accuracy of various clustering methods(%)

data sets	k-means	k-medoids	PSO-Kmeans	SFLA-k-means
Iris	87.50	63.30	89.75	92.02
Wine	59.30	64.27	69.59	73.47
Balance-scale	34.20	54.85	49.24	61.73
Housing	50.40	56.36	52.59	65.30

Analysis of the results.The experimental results: by cluster analysis for four artificial data sets, the accuracy rate of this algorithm is higher than the other three algorithms.This article was explained that the mixed leapfrog combined with k-means, learn from each other, reducing the number of iterations, improving the accuracy of k-means clustering algorithm, while speeding up the convergence rate. Prove SFLA-k-means algorithm is efficient.

Conclusion

This paper presents an algorithm based on SFLA k-means clustering algorithm,this algorithm on the basis of k-means clustering algorithm,overcome the accuracy of unstable because k-means sensitive to the initial cluster centers and lower accuracy rate and other issues.Through simulation data sets, compare the algorithm with PSO-Kmeans algorithm, K-means algorithm, K-medoids algorithm, this paper proved that SFLA-k-means algorithm is feasible and has a high accuracy rate.

Keywords: super-resolution, image sequence, Regularization

Abstract. The super-resolution reconstruction technology is proposed in this paper to overcome the image degradation of shipboard optical detection system. Firstly, establish the super-resolution observation model, then analysis the inadequate of traditional regularized method through the modulation transfer function and proposed a modified regularized algorithm, experimental results shows that the proposed method has the better visual effect and objective indicators. It is a feasible method to enhance reconstruction quality of the system.

Introduction

Shipboard optical detection system including infrared, television, shimmer and other sensing devices, the system plays a key role in detecting offshore and low-altitude targets. The detection accuracy of shipboard optical detection system not only affects the integrated battle effectiveness of warship, and even determine the warship's survival in battlefield environment. Warship works in complex and harsh environment, atmospheric attenuation, system noise and other factors will lead the system result in lower image spatial resolution.

The most direct way to improve the image resolution is upgrading the hardware of optical detection system, but sometimes there are many limitations of this way. Therefore, the study to improve image resolution can compensate the lack of hardware to a certain extent. Super-resolution technology can reconstruct high-resolution images through processing low-resolution sub-pixel image sequence without changing the hardware of imaging system[1]. Super-resolution is more flexble and economic in many conditions and has a broad application prospects, it is currently a hot spot of international image processing field, even in instrument design[2]. In super-resolution image reconstruction process, the core issue is the process of seeking to satisfy the indefinite equations, the noise in the process of solving the original low-resolution image sequence will be transmitted to the reconstructed images, which will lead noise in SR image increases and PSNR decreases[3]. The registration errors in the process will result in reconstruction errors.

In this paper, the registration error in super-resolution reconstruction image was analysised and researched, to subppress the artifacts caused by registration errors and noise in the reconstructed images, propose a regularized reconstruction using Gaussian Markov random field priori model based on Lee's method[4], Experiment results show that compared to the traditional Tikhonov method, the proposed method is better at PSNR and visual effects.

1 Super-resolution reconstruction model

To reconstruct the image of shipboard optical detection system, the most important issue is to establish the observation model from ideal high-resolution images to low-resolution images actual obtained. In practice, the ideal high-resolution image in the imaging process will be affected by deformation, blur, down sampling and noise, causing the image quality degenerated. Assuming low-resolution image sequence $\{y_k, k \in [1, N]\}$ contain N frame images, the size of image is $M \times N$; x is the high-resolution image which size is $Mp \times Nq$, the degeneratin progress from x to y can be expressed as:

$$y_k = DB_k M_k x + n_k \qquad k \in [1, N] \tag{1}$$

D is the decimation matrix, B_k is the blurring matrix caused by PSF(point spread function)[5] or diffraction limit, M_k is the geometric warp matrix caused by motion deformation, n_k is the distributed additive noise. From the flow chart Fig.1 we can see the super-resolution progree is based on the low-resolution image sequence information.

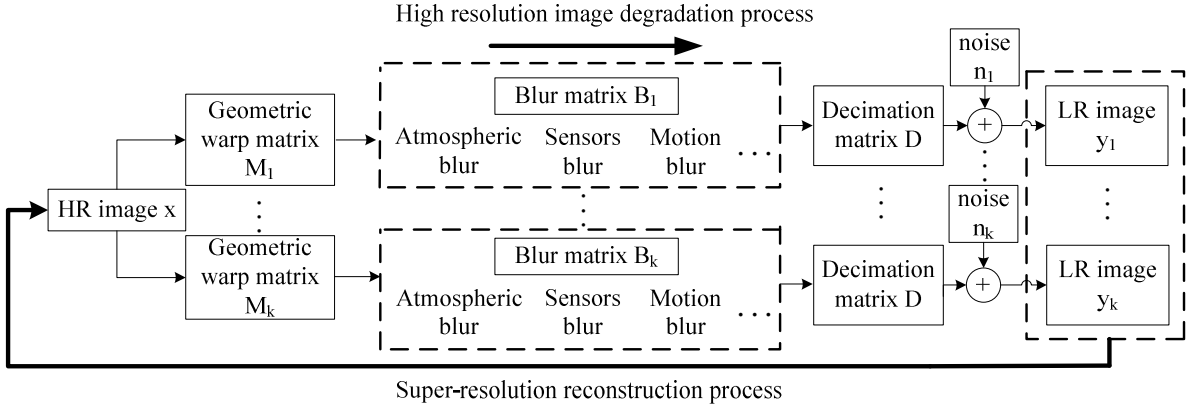

Fig. 1 Super-resolution reconstruction observation model

Assuming the degeneratin matrix $A_k = DB_kM_k$, the formula (1) became:

$$y_k = A_k x + n_k,\ k \in [1, N]. \tag{2}$$

The estimation value of high-resolution image $\hat{x}_k$ have the following relationship between low-resolution image sequence, H is transformation matrix:

$$\hat{x}_k = Hy_k \tag{3}$$

The reconstruction error obtained by formula (2), (3) can be expressed as:

$$\| \hat{x}_k - x_k \| = \| (HA_k - 1)x_k + Hn_k \| \le \| (HA_k - 1)x_k \| + \| Hn_k \| \tag{4}$$

From the formula above we can see there are two parts of reconstruction errors in it: the first part indicates that errors relate to local properties of original high-resolution image x, caused by reconstruction; the second part indicates that errors relate to noise n_k with global characteristics, which are not reconstructed noise, but the noise diffusion in SR image by reconstruction.

2 Analysis of the reconstructed image based on modulation transfer function

By the analysis above can see the super-resolution reconstruction will not only cause noise diffusion in SR image, but also cause errors in the reconstruction process. This paper use MTF(modulate transfer function) to analysis the errors caused by reconstruction, because the super-resolution reconstruction progress is also the process to process sensing devices data[6], the MTF of the system can be expressed as:

$$MTF_i = \frac{\sin(\pi\alpha f)}{\pi\alpha f} = \sin c(\alpha f) \tag{5}$$

In the above formula, α is the size of sensor sensitivity cell, f is spatial frequency. When the sensor is two-fold oversampling image acquisition system and sensor sensitivity cell deflection is the strict sense of $\alpha/2$, the MTF is:

$$MTF = \sin c(\frac{\alpha f}{2}) \tag{6}$$

In over-sampling system, sensitive cell registration determines the images registration. When the over-sampling sensitive cell registration is not the strict sense $\alpha/2$, the offset between the real position and the ideal position is $\Delta\alpha$. Assuming $\Delta\alpha = k\alpha$, $k \in [0,0.5]$,the two adjacent sampling points from the ideal state is changed from $\alpha/2$ to $(1/2+k)\alpha$. So the sensitive components registration error cause the image registration error, equivalent to the change of sampling frequency, the MTF change to:

$$MTF = \sin c[(1/2+k)\alpha f] = \sin c[(1+2k)\frac{af}{2}] \tag{7}$$

Compare formula(7) with formula(6), $(1+2k)$ is the impact of registration error to MTF, it will cause the reconstruction error[7].

The essence of super-resolution reconstruction is using additional data on a related sequence of frame bandwidth extrapolation to increase high-frequency information, such as image edges and details. The registration error affect the high frequency portion more than the low frequency portion that will cause the resolution of reconstruction image lower than ideal condition[8].

3 The modified regularized reconstruction algorithm

Super-resolution is an ill-posed problem[9], in order to obtain a stable solution, the regularization method using prior model to constraint on the solution is needed. Through the analysis in charpter 2 and chartper 3 we know that the registration error and noise will cause reconstruction error, the error will lead to different artifacts in reconstructed image. The traditional regularization method use the Laplace priori model can smooth the artifacts in SR images, but it will also cause the loss of image detail. This paper propose a regularization Algorithm based on Lee's method using GMRF(Gaussian Markov random field) priori model, can smooth image artifacts while preserving image detail.

The regularization formula of this paper proposed is:

$$\hat{x} = \arg\min_{x}\{\sum_{k=1}^{N} \| y_k - DB_k M_k x \|^2 + \lambda \sum_{c\in C}\sum_{l=1}^{4} \beta(d_c^l(x))\} \tag{8}$$

The second part of formula (8) is the regular item, the priori information is introduction by this part.

$$\beta(i) = \begin{cases} i^2 & , \quad i \le \alpha \\ 2\alpha |i| - \alpha^2 , & i > \alpha \end{cases} \tag{9}$$

$$\begin{cases} d_c^1(x(m,n)) = x_{m-1,n} - 2x_{m,n} + x_{m,n+1} \\ d_c^2(x(m,n)) = x_{m-1,n} - 2x_{m,n} + x_{m+1,n} \\ d_c^3(x(m,n)) = 0.5x_{m+1,n-1} - x_{m,n} + 0.5x_{m-1,n+1} \\ d_c^4(x(m,n)) = 0.5x_{m-1,n-1} - x_{m,n} + 0.5x_{m+1,n+1}) \end{cases} \tag{10}$$

$$\lambda = \sqrt{\frac{\sum_{c\in C}\sum_{l=1}^{4} \beta(d_c^l(u))}{\| y_k - DB_k M_k x \|^2 + \xi_k}} \tag{11}$$

The GMRF not only emphasizes the smoothing constraints, and considers the distribution of the image pixels to preserving image details. The Regularization parameters λ is is no longer a global parameters, which can adaptive changing with the image region characteristics.

4 Experimental results and analysis

To illustrate advantages and effective of the proposed algorithm, using "cameraman" image to test, the original high-resolution iamge, Degraded image and reconstructed iamges is showed in Fig. 2. Reconstructed images uses PSNR(peak signal to noise ratio) and SSIM(structure similarity image measure) for evaluation.

$$PSNR = 10\log_{10}\frac{L^2 N_1 N_2}{\sum_{i=1}^{N_1}\sum_{j=1}^{N_2}[\hat{x}(i,j) - x(i,j)]^2} \tag{12}$$

$$SSIM = \frac{(2\mu_x\mu_{\hat{x}} + C_1)(2\sigma_{x\hat{x}} + C_2)}{(\mu_x^2 + \mu_{\hat{x}}^2 + C_1)(\sigma_x^2 + \sigma_{\hat{x}}^2 + C_2)} \tag{13}$$

(a) HR image (b) LR image (c) traditional method (d) this paper algorithm

Fig. 2 Super-resolution reconstruction results

Table 1 Comparison of cameraman image by different method

	PSNR	SSIM
Tranditional Regularization	20.612	0.7813
This paper Algorithm	21.382	0.8929

5 Conclusion

From the experimental results we can see, the proposed algorithm compare to the traditional regularization method has the better visual effect and the objective indicators. Provide a theoretical reference to enhance reconstruction quality for infrared and visible light images of Shipboard optical detection system.

Keywords: landslide, surge, DDA, numerical simulation, real velocity, dynamic

ABSTRACT: The surge wave induced by the landslide on reservoir bank is extremely disaster .The prediction of surge height is a difficult problem because the velocity of landslide is hard to obtain. The discontinuous deformation analysis (DDA) is able to simulate landslide movement with real time and acceleration. The whole movement process of Muzhuping landslide in the Qing river reservoir is simulated by DDA method, including startup, accelerating, deceleration and stop, and velocity along time is obtained. Last, empirical formula for computing surge height is discussed.

Introduction

Reservoir landslide is a common geological disaster in the process of reservoir water impounding, surge water caused by the disasters affect the dam and reservoir bank residents and river navigation the safety of the ship. Therefore, this problem attract extensive attention of the worldwide researchers. Landslide sliding process and the surge disaster prediction and estimation is an important content of landslide research. Landslide sliding is the complex process including static and dynamics mechanics, as well as velocity of landslide when sliding into the water is the key factor in surge analysis. The surge height must be based on a changing sliding velocity in the process of accumulation, so it is necessary to investigate the changing rules of landslide displacement and velocity based on the real time and stress-strain characteristics in the process of movement .The discontinuous deformation analysis method (DDA) is suitable for this problem [1-3].

In this paper, the failure and movement process of Muzhuping landslide in Shuibuya reservoir are simulated by DDA based on real time and dynamic equation. The displacement and velocity changing law of each part are studied in the process of landslide sliding, and then the velocity based on energy is obtained. Lastly, surge water height is predicted, which can evaluate the effect of landslide surge disasters.

The general situation of Muzhuping landslide

MuZhuping landslide is located in Shuibuya Reservoir of the Qing river , Hubei province，China. The landslide occurred in the gradually process of water storage (water level 250m-289m), submerged deposit front 50 ~ 60 meters, which is a large scale tractive landslide. The front of landslide firstly began to deform and collapse, and tract the back of landslide. A total of three times large scale sliding and collapse occurred, which formed a more than 80 m scarp. Total volume of the landslide is about 5 million m^3, and sliding distance is about 170m, which induce 10 meters high surge wave and formed a barrier lake in the river. The main induced reason is that reservoir water reduces the contact strength of rock and soil interface.

Sliding zone terrain like round-backed armchair, as shown in fig.1.Landslide consist of shale, limestone and marl, generally 20 ~ 80 m thick (geological section map as shown in fig. 2).

Fig.1 MuZhuping landslide

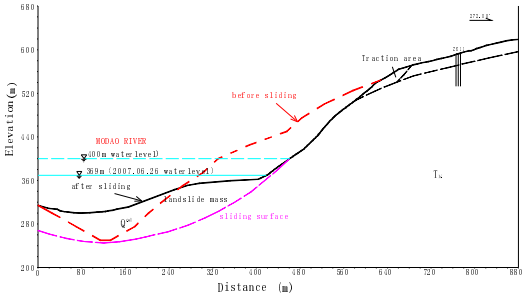

Fig. 2 Geological section map

The DDA model

Discontinuous Deformation Analysis (abbreviated DDA)[1] was proposed by Dr Shi Genhua in 1989. DDA method is suitable for discontinuous medium such as joint rock stress analysis. This method has the full dynamic format, real time, strict balance equation, the advantages of the large deformation and contact simulation. It can simulate landslide from the start, sliding process, accurate calculation of displacement, velocity and energy changes, and accumulation form.

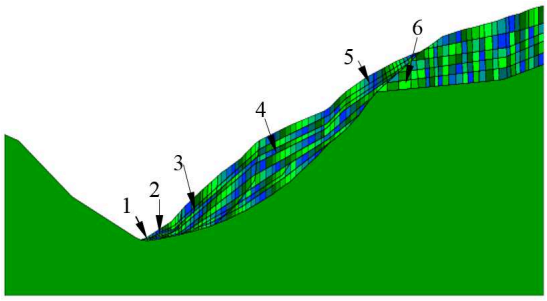

Fig.3 Block system of DDA model

According to the rock mass structure characteristic of the landslide geological profile and landslide, DDA analysis model is set up, as shown in figure 6.which include 524 blocks in the system. To show the calculation results, six monitoring points are marked in the model, as shown in fig. 3.

Table 1 DDA computation model parameter table

material	Cohesion(MPa)	Friction Angle(°)	unit weight（kN/m^3）
bed rock	0.5～1.0	30～40	26.5
The sliding body	0.15～0.5	17～25	22
Sliding zone (underwater)	0.01～0.02	5～15	
Sliding zone (over water)	0.05～0.03	3.6～20	

Mechanics parameters consider the result of the laboratory test and field geological investigation (see table 1). The different velocities are obtained for computing surge wave height that include monitoring points velocity, average velocity and energy velocity (based on the average kinetic energy) through DDA.

Simulation result analysis

In section 4 of this paper, we describe the preliminary results of the numerical simulation analysis by DDA. According to the displacement and speed of these monitoring points (1#-6# points) whether have occurred significant increasing determine whether landslides. By the velocity and displacement with time (as shown in fig.4～ fig.6), it show that landslide is at a long time creep stage. The forefront of landslide indicate slight deformation and compressive stress concentration in the 0 to 40 second, while the displacement and velocity of the upper points are small.

After a long time of energy accumulation, landslide suddenly accelerate at 50 s and the displacement sharply increase. When the displacement and velocity are reaching considerable value, front and central of landslide successively slide, and back parts of landslide body drop.

The results indicate that the startup from leading edge, and leading edge deformation velocity of deformation is always greater than the middle and back part of the landslide. Therefore MuZhuping landslide is due to reduced mechanical parameters of landslide sliding surface.

The process of landslide is as shown in fig.9，which give the landslide shape of 10000 time steps and 3000 time steps. When the calculation is 10000 steps, the sliding displacement of landslide is small (fig.7 (a)); the great changes have taken place in the overall form when 30000 time steps (fig.7 (b)), and the shape of the MuZhuping landslide and the actual landslide shape are very close at this time.

There are some method for estimation of landslide surge height, but there is no unity. The Panjiazheng formula[4] are used to evaluate surge height .Maximum speed is 6.97 m/s (point 1) by calculating, but it do not represent the overall speed of landslides, and landslide surge calculation will be larger. While energy speed of landslide is 5.4 m/s, and according to Panjiazheng formula to calculate, the surge height is 12.6 m, which is compatible with the actual situation.

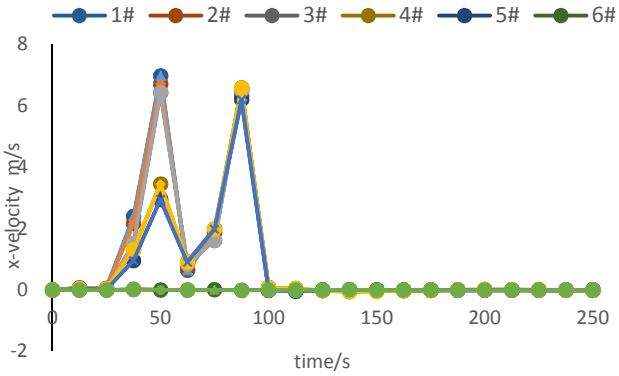

Fig. 4 x-velocities of monitoring blocks

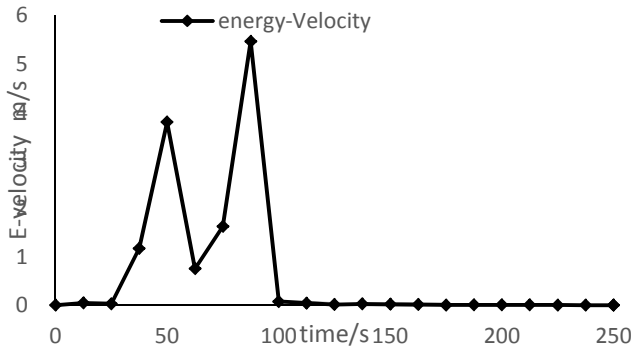

Fig. 5 Energy velocity of monitoring blocks

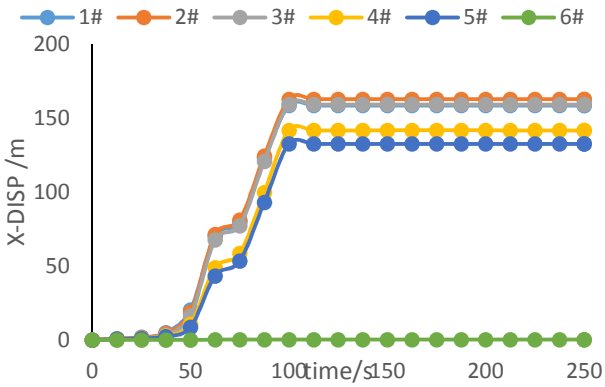

Fig. 6 x-displacements of monitoring blocks

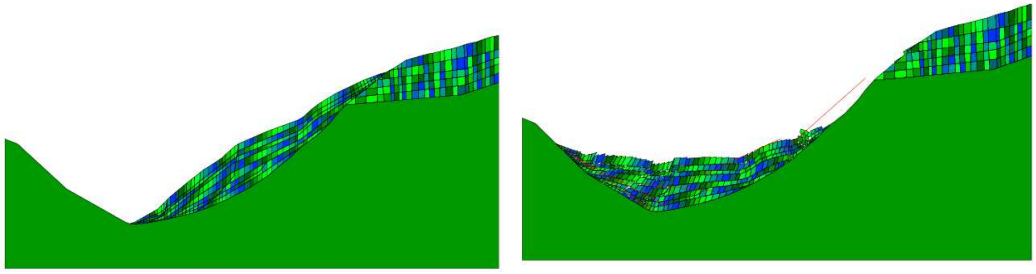

（a）10000 time step (b)30000 time step

Fig. 7 Displacements and shape of landslide along time step

Conclusion

DDA is an effective method to simulate landslide startup, acceleration and the whole process and calculate the surge velocity. It overcome the problem that traditional limit equilibrium method can not consider the effect of topography and lithology.

Muzhuping landslide is simulated by DDA method, which include the whole landslide sliding process, movement time, velocity, and then calculate the initial surge of landslide surge height. The results show that the largest velocity is 5.4 m/s, and total time is 100s, as well as maximum sliding distance is163 m.

Energy speed is good for estimate the height of the landslide surge, and the surge height is 12.6 m .The results shows that the landslide surge height based on energy velocity is close to the height of the actual situation.

State-Space Model and Simulation for Dynamic Stall

Weidong Lei[1,a], Guocai Hu[1b] and Quan Liu[1]

[1] Naval Aeronautical and Astronautical University, Yantai 264001 China

[a]weidong319@sina.com, [b]guocaihu11@sina.com

Keywords: dynamic stall; unsteady aerodynamics; state-space equations; Beddoes-Leishman model.

Abstract. Because of the complexity of the progress of dynamic stall, the characteristic of dynamic stall of airfoil is always the difficulty of aerodynamics. A time-domain model has been formulated to represent the unsteady lift and pitching moment characteristics of a two-dimensional airfoil undergoing attached-flow conditions in a compressible flow and dynamic stall. The model is given as a set of first order differential state equations. The Beddoes-Leishman model was presented through modeling the effects of attached flow, separated flow and dynamic stall in the paper. A modified method is presented which includes a new stall-onset criterion and improves the position and separation conditions of the leading edge vortex, so that the B-L model is adaptive for lower Mach numbers. Then, the normal force and pitching moment on NACA0012 airfoil was calculated and compared with available experimental data to validate the reliability of the model.

Introduction

Within a helicopter rotor flow field, the blades encounter complex time varying changes in aerodynamic angle of attack due to imposed control inputs, the dynamic motion of the blades, and large local variations in inflow velocity that arise from the complex three-dimensional vortex wake system. Typically, dynamic stall occurs on the retreating blade under conditions of high blade loading and in high speed forward flight[1]. The rotor operational limitations are all determined by the onset of transient flow separation such as dynamic stall.

The B-L model was originally introduced by Beddoes[2-3] and deals with the unsteady lift and pitching moment. Then this model was refined by Leishman[4-6] and became a complete model for unsteady lift, drag, and moment. The B-L model includes the effect of the unsteady two-dimensional inviscid wake, the effects of trailing and leading edge flow separation, and compressibility effects similar to the Piston Theory. State-space formulations of the B-L model have been published for attached flow conditions in [7-8].

In this paper, it is demonstrated how a relatively elegant and computationally efficient method can be created and used to credibly reproduce the dynamic stall characteristics of an airfoil section given, primarily, the static (nonlinear) airfoil lift and pitching moment characteristics. The method draws on the work of both Leishman[9] and Sheng[10], to establish a system of first order ordinary differential state equations which represent specific aspects of the unsteady airfoil behavior. The method is useful in the performance and aeroelastic response analysis of helicopter rotors and propellers. To support the development of the method, illustrative comparisons with experimental data are presented for the unsteady lift, pitching moment on a typical helicopter rotor airfoil undergoing oscillatory pitch forcing into dynamic stall.

Attached Flow Behavior

A prerequisite in any unsteady aerodynamic theory is the ability to accurately represent the unsteady aerodynamic response under attached flow conditions. The indicial response is particularly useful since the state equations representing the unsteady airfoil behavior can be obtained by the direct of Laplace transforms to the indicial response to get the aerodynamic transfer function.

In the present analysis, the indicial response functions given by Beddoes[3] and later refined by Leishman[6] are used. These indicial responses are assumed to be composed of the sum of two parts; one for the initial noncirculatory loading (which comes from piston theory) and another for the circulatory loading which builds up quickly to the steady state value. In general, the indicial normal force and quarter-chord pitching moment response to a step change in angle of attack α and a step change in pitch rate $q = \dot{\alpha}c/V$ can be written as

$$C_{N_\alpha}(S) = \left[\frac{4}{M}\phi_\alpha^{\mathrm{I}}(S,M) + \frac{2\pi}{\beta}\phi_\alpha^{C}(S,M)\right]\alpha . \tag{1}$$

$$C_{M_\alpha}(S) = [-\frac{1}{M}\phi_{\alpha M}^{\mathrm{I}}(S,M) + \frac{2\pi}{\beta}\phi_\alpha^{C}(S,M)\cdot\left(\frac{1}{4} - x_{ac}(M)\right)]\alpha . \tag{2}$$

$$C_{N_q}(S) = \left[\frac{1}{M}\phi_q^{\mathrm{I}}(S,M) + \frac{\pi}{\beta}\phi_q^{C}(S,M)\right]q . \tag{3}$$

$$C_{M_q}(S) = [-\frac{7}{12M}\phi_{qM}^{\mathrm{I}}(S,M) - \frac{\pi}{8\beta}\cdot\phi_{qM}^{C}(S,M)]q . \tag{4}$$

Where the indicial response function ϕ_α^C, ϕ_α^{I}, $\phi_{\alpha M}^{\mathrm{I}}$, ϕ_q^{I}, ϕ_q^C, ϕ_{qM}^{I} and ϕ_{qM}^C are expressed in terms of both aerodynamic time S and the Mach number M.

It can be readily shown that by rearranging all(eight)state equations for attached flow conditions, they can be represented as a diagonal canonical set of state equations

$$\dot{\boldsymbol{x}} = \boldsymbol{A}\boldsymbol{x} + \boldsymbol{B}\begin{Bmatrix}\alpha\\ q\end{Bmatrix}. \tag{5}$$

$$\begin{Bmatrix}C_N^P\\ C_M^P\end{Bmatrix} = \boldsymbol{C}\boldsymbol{x} + \boldsymbol{D}\begin{Bmatrix}\alpha\\ q\end{Bmatrix}. \tag{6}$$

Where the matrices are of the form

$$A = diag\left[a_{11}\quad a_{22}\quad a_{33}\quad a_{44}\quad a_{55}\quad a_{66}\quad a_{77}\quad a_{88}\right]; B = \begin{bmatrix}1 & 1 & 1 & 0 & 1 & 1 & 0 & 0\\ 0.5 & 0.5 & 0 & 1 & 0 & 0 & 1 & 1\end{bmatrix};$$

$$C = \begin{bmatrix}c_{11} & c_{12} & c_{13} & c_{14} & 0 & 0 & 0 & 0\\ c_{21} & c_{22} & 0 & 0 & c_{25} & c_{26} & c_{27} & c_{28}\end{bmatrix}; D = \begin{bmatrix}4/M & 1/M\\ -1/M & -7/12M\end{bmatrix}.$$

The total aerodynamic lift and pitching moment response to an arbitrary time history of α and q can be obtained from the above state equations by integrating.

Stall Onset

The most crucial aspect of the modeling of dynamic stall is the identification and representation of the conditions for the onset of leading edge separation. The criterion was evaluated by Beddoes within the context of rotor airfoil performance, under both steady and unsteady conditions.

From an analysis of airfoil static test data, a critical value of C_{N_1} (static) is close to the maximum static C_N. Thus a Mach number dependent separation onset (stall) boundary may be defined. A typical boundary for the NACA 0012 airfoil is shown in Fig.1.

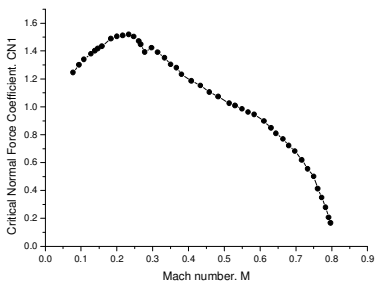

Fig.1 Stall boundary for the NACA0012 airfoil section

For unsteady conditions, there is a lag in $C_N(t)$ with respect to the forcing, however there is also a lag in the leading edge pressure response $P(t)$ with respect to $C_N(t)$. To implement the critical pressure criterion under unsteady conditions, a first order lag may be applied to $C_N(t)$ to produce a substitute value $C_N'(t)$ with the presumption that whatever properties apply to $P(t)$ must also apply to $C_N'(t)$. This representation may be written as the differential state equations

$$\begin{cases} \dot{\boldsymbol{x}}_9 = -\dfrac{\boldsymbol{x}_9}{T_p} + \dfrac{C_N^p(t)}{T_p} \\ C_N'(t) = \boldsymbol{x}_9 \end{cases}. \tag{7}$$

Where the time constant T_p is a function of Mach number.

Thus by monitoring the value of $C_N'(t)$ the onset of leading edge/shock induced separation under dynamic conditions will be initiated when $C_N'(t)$ exceeds the critical $C_{N_1}^{'}(M)$ boundary. Furthermore, if the vale of $C_N'(t)$ is monitored throughout the calculation into stall, then it may be used as an indicator for the conditions which permit flow reattachment, i.e. if $C_N'(t) < C_N'$.

Trailing Edge Separation

A phenomenon that is also involved in most types of airfoil stall is progressive trailing edge separation. The associated loss of circulation due to trailing edge separation introduces a nonlinear force and moment behavior, especially with the cambered airfoils more typically used on modern helicopters. When the primary source of separation is at the leading edge or the foot of a shock wave it appears that this is generally sufficient to promote some separation at the trailing edge and hence initiate some nonlinear behavior in the force and moment response.

A specific case of Kirchhoff flow is a simple model for the trailing edge separation phenomenon in which the airfoil normal force coefficient, C_N, may be approximated as

$$C_N = C_{N_\alpha}(M)\left(\frac{1+\sqrt{f}}{2}\right)^2 \alpha. \tag{8}$$

where f is the trailing edge separation point. Thus, if the separation point can be determined it is a trivial calculation to determine the normal force.

The relationship between α_1 and f can be generalized empirically in a fairly simple manner using the relations

$$f = \begin{cases} 1 - 0.3\exp\left[\left(\alpha_f - \alpha_1\right)/S_1\right], \alpha_f < \alpha_1 \\ 0.04 + 0.66\exp\left[\left(\alpha_1 - \alpha_f\right)/S_2\right], \alpha_f > \alpha_1 \end{cases}. \tag{9}$$

Where the effective angle of attack α_f is defined as

$$\alpha_f = \frac{C_N^{'}(t)}{C_{N_\alpha}(M)}. \tag{10}$$

The coefficients S_1 and S_2 define the stall characteristic, while α_1 defines the break point corresponding to $f = 0.7$. S_1, S_2 and α_1 are determined empirically for each airfoil and vary with Mach number.

A general expression for the pitching moment behavior cannot be obtained from Kirchhoff theory and an alternative empirical relation must be formulated. From the airfoil static data, the center of pressure at any angle of attack may be determined from the ratio C_M / C_N. The variation can be plotted versus the corresponding value of the separation point and fitted in a least squares sense to the form

$$\frac{C_M}{C_N} = K_0 + K_1(1-f) + K_2\sin\left(\pi f^m\right). \tag{11}$$

where $K_0 = (0.25 - x_{ac})$. The constant K_1 gives the direct effect on the center of pressure due to the growth of the separated flow region and the constant K_2 helps describe the shape of the moment break at stall. The values of K_0, K_1, K_2 and m can be adjusted for different airfoils, as necessary, to give the best moment reconstruction. Typically, $m = 2$.

The additional effects of the unsteady boundary layer response may be represented by applying a first order lag to the value of f' to produce the final value for the unsteady trailing edge separation point f. In state variable form this additional lag in the response may be represented as

$$\begin{cases} \dot{x}_{10} = -\dfrac{x_{10}}{T_f} + \dfrac{f'(t)}{T_f} \\ f'(t) = x_{10} \end{cases}. \tag{12}$$

As in the case of T_P, the time constant T_f is Mach number dependent.

Finally, the nonlinear normal force $C_N^f(t)$ with the modified unsteady trailing edge separation point f' is given by

$$C_N^f(t) = C_{N_\alpha}(M)\left(\frac{1+\sqrt{f'}}{2}\right)^2 \alpha_E(t) + C_{N_n}^I. \tag{13}$$

and the pitching moment by

$$C_M^f(t) = \left[k_0 + k_1(1-f') + k_2 \sin\left(\pi (f')^m\right)\right] \cdot C_N^c(t) + C_{M0}. \tag{14}$$

Where $C_{N_n}^I$ is noncirculatory normal force, and C_N^c is the circulatory normal force coefficient and C_{M0} is the zero lift moment.

Modeling of Dynamic Stall

The general case of dynamic stall involves the formation of a vortex near the leading edge of the airfoil which subsequently separates from the surface and is transported downstream.

An approximate, but physically acceptable, model for the dynamic stall process has been formulated by viewing the vortex lift contribution $C_N^v(t)$ as an excess circulation which is not shed into the airfoil wake until some critical condition is reached. The critical condition used here is of course when $C_{N_1}^{'}$ exceeds C_{N_1}. At this point, catastrophic flow separation occurs and the accumulated circulation passes over the airfoil and into the wake. The vortex lift process can be represented by the differential state equations

$$\begin{cases} \dot{x}_{11} = -\dfrac{x_{11}}{T_v} + \dfrac{\dot{C}_v}{T_v} \\ C_N^v(t) = x_{11} \end{cases}. \tag{15}$$

Where $C_v = \begin{cases} C_N^C\left[1 - \left(1+\sqrt{f'}\right)^2/4\right]\tau_v / m_v T_{vl} & \tau_v \le 2T_{vl} \\ 0 & \tau_v \le 2T_{vl} \end{cases}$

as derived from the Kirchhoff approximation, and T_v is time constant. To track the position of the vortex, a nondimensional vortex time parameter τ_v (in semi-chords) is used such that $\tau_v = 0$ at the onset of separation conditions and $\tau_v = T_{vl}$, when the vortex reaches the trailing edge.

The centre of pressure on the airfoil also varies with the chordwise position of the vortex and will obtain a maximum value when the vortex reaches the trailing edge. Based on an analysis of much experimental data involving dynamic stall over a wide range in Mach number, a fairly general representation of the centre of pressure behaviour was formulated empirically as

$$CP_v = 0.25\left[1-\cos\left(\frac{\pi\tau_v}{T_{vl}}\right)\right]. \tag{16}$$

Finally, the increment in pitching moment about the quarter-chord due to the aft-moving centre of pressure is given by

$$C_M^v = -CP_v C_N^v. \tag{17}$$

From the above, the required total loadings can be obtained by superposition. For example, the total normal force coefficient C_N under dynamic stall conditions is given by

$$C_N(t) = C_N^f(t) + C_N^v(t). \tag{18}$$

The total pitching moment coefficient C_M under dynamic stall conditions is given by

$$C_M(t) = C_M^f(t) + C_M^v(t). \tag{19}$$

Results and Discussion

This section documents a selection of comparisons of the aerodynamic model with unsteady test data. The state-space equations was calculated by the method of direct integration.

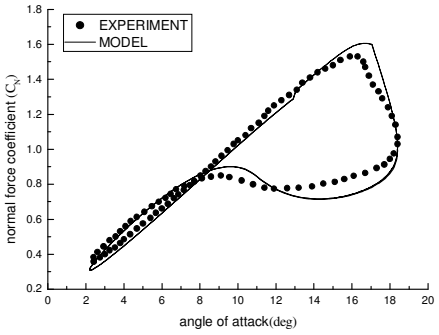

Fig.2 Normal force vs angle of attack

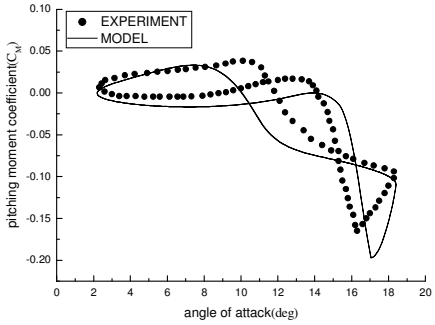

Fig.3 Pitching moment vs angle of attack

Conclusions

1) Typical normal force. and pitching moment responses are shown in sample.1, for a harmonic pitch oscillation under attached flow conditions. It should be noted that, for a pure sinusoidal oscillation under attached flow conditions, normnally elliptical lift and moment loops should be obtained.

However, it can be seen that there is some distortion in the loops, particularly for the pitching moment. This behavior was traced to a significant third harmonic in the pitch forcing that has the effect of in creasing the pitch rate contributions to the airloads near the maxim and minimum angles of attack.

2) In sample.2, strong dynamic stall occurs. It can he seen that the vortex shedding contributes a moderate increment to C_N, but gives a particularly large increase in nose-down pitching moment. The maximum lift and minimum moments are predicted very accurately along with the phasing of the loads during stall. Flow reattachment (indicated by the return to the nominally elliptical shapes of the loops) is delayed to a fairly low angle of attack during the downstroke of the motion. It should be noted that two successive cycles of oscillatory pitch data are shown, and this serves to illustrate the inherent variability of the aerodynamic loads in the separated flow regime.

Keywords: CFD, RNG *k-ε* turbulence model, Uniformity, gas distributor.

Abstract. This paper investigated a new type of gas distributor with two chambers by CFD software. The distributor has a natural gas inlet and nine nozzle outlets. For the investigation of this project, the mass flow rate of the distributor was analyzed in this paper to provide a way to optimize the structure of distributor. The N-S equations approached with the RNG k- ε turbulence model and the discretization were employed second order upwind. The simulation results will provide a number of useful suggestions and references for the further design.

Introduction

Over the past few years, quite a few large gas fields have been proven, and a huge amount of natural gas has been recovered. China is building a high capacity pipeline for transporting natural gas from the west regions to the east industrialized coastal areas, so natural gas will find wider applications than ever [1]. However, energy conservation and emissions reduction have been the subject of today's society. Therefore, various kinds of equipments about gas distribution have been studied and developed for improving performance. The natural gas distributor as one of the main components of gas equipment has significant function to gas distribute. So optimize the geometry structure of it for perfect uniformity of mass flow rate is becoming more and more necessary.

The traditional way of design-manufacture-further improvements requires long transformation time, high range is usually disappointing. Computational Fluid Dynamics (CFD) can provide detailed information on airflow patterns and ensure convenient design of agricultural equipments [2]. Along with the rapid development of High Performance Computer (HPC), numerical calculation of high strength has become reality. With the recent advances in computing power, the process of creating a CFD model and analyzing the results has become much less labor-intensive, reducing the time and therefore the cost [3].

The main task of this paper was to assess the characteristics of mass flow rate of nozzles. Based on the uniformity of mass flow rate, Dhotre and Joshi [4] simulated a coupled system consisting of gas chamber and a bubble column and estimated the uniformity of the gas distribution. Through the efforts of this paper will help us to obtain further method for optimizing design.

Modeling and Governing Equations of the distributor

Structure. Fig.1 shows the schematic of the gas distributor that was developed as the main part of this study. In the process of operation, the gas attaches the chambers through the gas inlet. And all of the gas was assign to the nozzles (form number 1 to 9). The size of special parts has been presented in Fig.1. Solenoid value was set at the bottom of left chamber. Moreover, it can adjust according to the power.

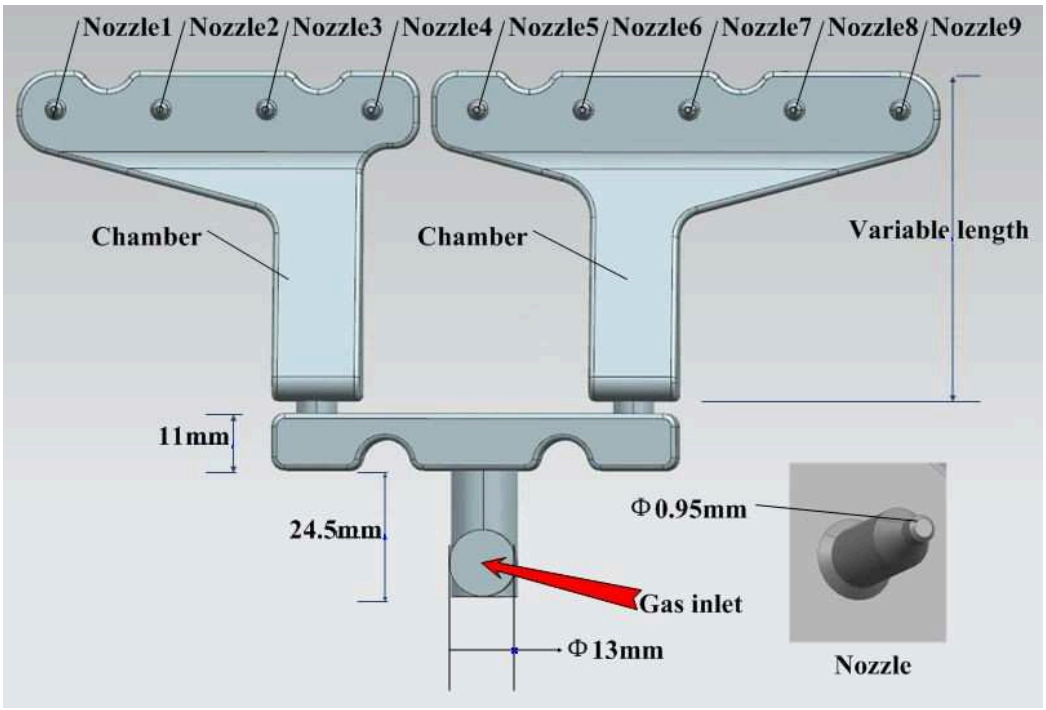

Fig. 1 Schematic of the gas distributor

Meshing. The pretreatment software Gambit was used in the process of grid building. It was that the throats and the parts of nozzle were divided to reduce the total number of cells.

Boundaries. The inlet boundary condition in this model was selected velocity inlet. And the inlet velocity was 3.348m/s. The exports of natural gas distributor were defined as pressure-outlet.

Equations. In the rectangular coordinate system with the absolute reference frame, the steady-state conservation equations of continuity, momentum, kinetic energy k and dissipation rate ε of turbulence pulsation can be expressed in the following form [4, 5]:

$$\nabla(\rho\mathbf{u})=0. \tag{1}$$

$$\nabla(\rho\mathbf{uu})=-\nabla p+\nabla\tau+\rho g \tag{2}$$

$$\nabla(\rho\mathbf{u}k)=-\nabla\left(\frac{\mu_{\text{eff}}}{\sigma_k}\nabla k\right)+G-\rho\varepsilon \tag{3}$$

$$\nabla(\rho\mathbf{u}\varepsilon)=\nabla\left(\frac{\mu_{\text{eff}}}{\sigma_\varepsilon}\nabla\varepsilon\right)+C_{\varepsilon 1}\frac{\varepsilon}{k}G-C_{\varepsilon 2}\rho\frac{\varepsilon^2}{k} \tag{4}$$

The turbulent viscosity is then related to k and ε by the expression:

$$\mu_{\text{eff}}=\mu+C_\mu\rho\frac{k^2}{\varepsilon} \tag{5}$$

The coefficients $C_{\varepsilon 1}$, $C_{\varepsilon 2}$, C_μ, σ_k, σ_ε are the k and ε model parameters and the following values selected: $C_{\varepsilon 1}$=1.44, $C_{\varepsilon 2}=1.92$, $C_\mu=0.09$, $\sigma_k=1.0$, $\sigma_\varepsilon=1.3$. The term G in Eqs. 2 and 3 is the production of turbulent kinetic energy and described by τ: $\nabla\mathbf{u}$ where $\tau=-\mu_{\text{eff}}\left[\nabla\mathbf{u}+(\nabla\mathbf{u})^{\text{T}}\right]$.

In order to investigate the uniformity of the out flow rate at natural gas distributor outlet, the following two evaluation indexes [6, 7] have been set up for reference.

$$E=\frac{\left|M_i-\overline{M}\right|}{\overline{M}}\times 100\% \tag{6}$$

Where E expresses the degree of deviation of out flow rate for each nozzle to the average that the sum of all the nozzles out flow rate.

$$S=\frac{\sqrt{\frac{1}{n\text{-}1}\sum_{i=1}^{n}\left(M_i\text{-}\overline{M}\right)^2}}{\overline{M}}\times 100\% \tag{7}$$

S is defined the maximum deviation that local out flow rate for the all nozzles. $\overline{M}$ is the average out flow rate for all of the nozzles, M_i denotes the out flow rate of each nozzle.

Summary

The CFD program used was CFD-14.5. This uses a Cartesian coordinate system with mixed mesh and solves the hydrodynamic equation set in a segregated manner. The pressure coupling was treated using the SIMPLE algorithm (Patankar [8]).

Fig.2 shows that the maximum and minimum mass flow rate are nozzle 2 and nozzle 6, respectively. At the same time, the E that present in Table 1 are 0.147% and 0.138%, respectively. However, it can be noticed that the mass flow rate of each nozzle have a relatively small S, which might create a uniform mass flow rate to a significant degree.

And the value of S is 1.1×10^{-3} in this paper, which could acceptable to a significant degree. The value of S gives expectable information that implies better uniformity of mass flow rate to every nozzle. From the previous simulations to engineering, the results that presented in this article are no doubt for the credibility.

Table 1 The values of E

The number of nozzle	1	2	3	4	5	6	7	8	9
E (%)	0.135	0.147	0.144	0.031	0.041	0.138	0.081	0.066	0.068

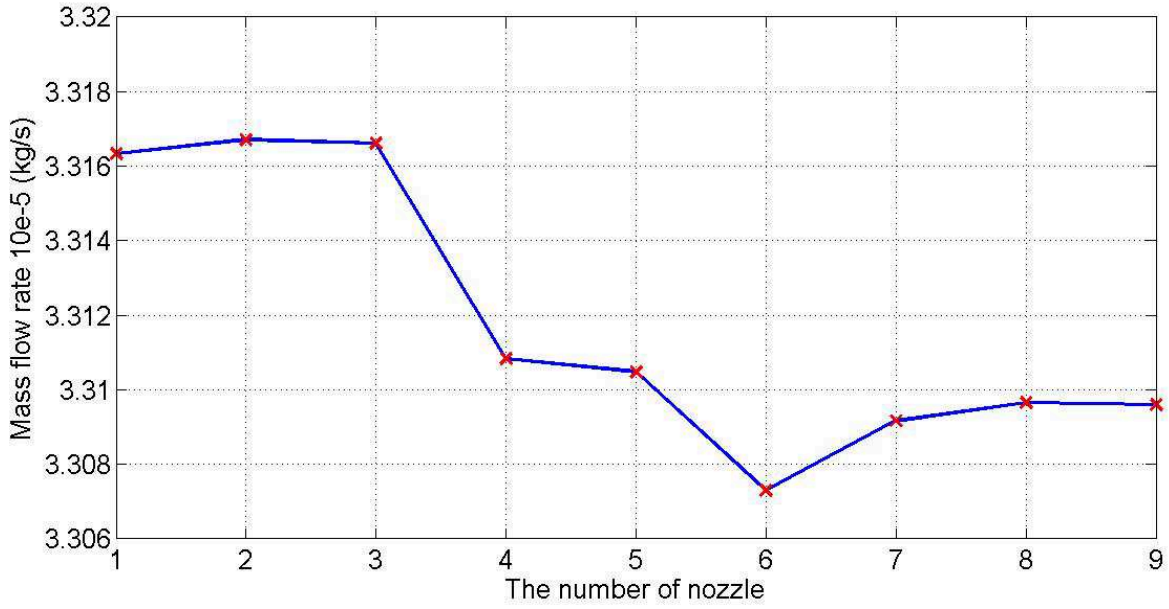

Fig. 2 Mass flow rate of nozzles

From the information reported in this paper, it may be possible to select the design parameters of distributor and natural gas chamber depending upon the desired level of uniformity of distribution.

Keywords: Weapons system-of-systems; capability ratio; synthesized weights; gaps assessment

Abstract. Weapon system of systems gaps assessment (WSoSCGA) is a key problem in the field of weapon demonstration research. Traditional methods have a lot of work to do and lack science. This paper tries to solve this problem in a novel way based on capability ratio. All the criteria should be normalized differently according to their own attributes. By combining the subjective weighting method and objective weighting method, synthesized weights are formed and inputted into a framework to determine their relative capability values. Then we can evaluate weapon system of systems gaps by comparative analysis. In contrast with traditional methods, there is no need to calculate specific capability value of each SoS for gaps assessment. At last, a case is conducted to illustrate its utilization and demonstrate its effectiveness and feasibility for WSoSCGA.

Introduction

Generally speaking, weapon system-of-systems (WSoS) is understood to be an assemblage of different weapon systems that are fundamentally collaborative and related with each other [1]. To date, assessment and evaluation of WSoS is a key problem in weapon demonstration research. And the studies related with capability gaps about WSoS are in the forefront of research. Capability gaps analysis [2], based on the capability demand analysis and capability evaluation, aims to make a deep analysis on WSoS' deficiencies and make timely adjustments at different time periods, according to different mission objectives and requirements for the future development.

To the best of our knowledge, there are few studies conducted in the capability gaps assessment at domestic and overseas. TTCP Joint Systems and Analysis Group [3] suggested using three different colors to represent different capacity gaps importance, based on experts' experience and knowledge, which is more suitable for strategic level. The latest edition of the "Capability based Assessment User Manual 3.0" in U.S [4] introduced their research briefly about the sorting of the ten capacity gaps related with biometrics, which in essence is a simplified AHP (analytic hierarchy process) method without considering some conflicting situations. Linkov [5] from U.S. Army engineering used multi-criteria decision analysis methods to solve multi-arms capability gaps in small arms project scheduling problem. Its deficiencies lie in excluding much incomplete preference information. Hristov [6] studied main methodological issues related to the prioritization of Required Operational Capabilities of the Bulgarian Armed Forces. However, a great amount of efforts must be done and uncertainties are not considered in the evaluation process. Welch from the U.S Sandia National Laboratories developed prioritized gaps using utility theory [7]. Obviously this assessment required system expert participation and opinion, which will no doubt lead to arbitrariness and obscurity.

It is apparent that none of these methods developed is perfect and all are far from ready to be used in practical applications. This paper tries to solve this problem in a very artful way. To begin with, all the criteria are normalized by comparing with different goal values. Then, synthesized weights are formed by combining the subjective weighting method and objective weighting method. These weights are inputted into a frame to determine each system's relative capability value. Then we can

evaluate WSoS gaps by comparative analysis based on capability ratio. Thanks to this uniqueness, there is no need to calculate the specific value of each WSoS, which is easy to operate.

The proposed hybrid framework

AHP, introduced by Saaty [8], aims to quantify relative priorities for a given set of alternatives on a ratio scale. The strength of this approach lies in organizing tangible and intangible factors in a systematic way, and providing a structured yet relatively simple solution to the decision making problems [9]. However, its limitation lies in its overreliance on the intuition of decision makers, which may lead to unreasonable results. Entropy was first introduced by Shannon to the Information Theory [10], which assigns a small weight to an attribute if it has similar attribute values across alternatives, because such attributes does not help in differentiating alternatives.

Considering these shortcomings, we propose a hybrid framework, integrating IEM (Information Entropy Method) and AHP to determine the weights instead of using AHP or IEM alone. The weights obtained from IEM are derived from characteristic data of alternatives themselves. As is shows in Fig .1, it displays an overview of the hybrid framework for WSoSCGA. All the criteria should be normalized according to corresponding standardization models. Then aggregation process is done to get relative values of each system. Comparative analysis can be made to the capability gaps between WSoS. The detailed process is as follows:

Step 1: Establish a unified combat capability index system. WSoS needs different combat missions under different operational backgrounds. In general, all kinds of SoS capability requirement can be regarded as a combination of communication capability, attack capability, mobility capability, defense capability, and security capability in a certain way [11]. Meanwhile, all these capabilities are supported by specific weapon category and each weapon category has more than one capability. Therefore, a certain mapping relationship is needed and established as below in Fig .2.

Step 2: Identify the equipment of both sides and determine the standardization models;

Step 3: Collect the characteristic data of different equipment and establish corresponding WSoS to be evaluated;

Step 4: Normalize all the indicators and obtain synthetized weights by subjective weighting methods and objective weighting methods;

Combat capability index standardization is to make measurements to all the indicators related to the combat capability and transform them into polymeric scores through certain mathematical methods.

Tactical and technical indicators can be divided into qualitative one and quantitative one and the standardized method varies each other. In this paper, experts were asked to use their knowledge and experience to make a judgment on the qualitative ones. For quantitative index, it can be divided into benefit and cost type according to the influence degree of the index value up on combat task. In the standardization process, the characteristic value divided by a given demand value is set as the score for the benefit indicator. And corresponding given demand value divided by the characteristic value is set as the score for the cost indicators. It is noteworthy that there is no practical significance for these relative values, while using alone. Anyway, it can reflect the superiority when comparing the capabilities between different WSoS with the same structures.

The weight obtained from AHP and IEM can be synthesized by the following equation to calculate the overall weight of the ith criterion, WSYNi :

$$w_{SYNi} = \frac{W_{AHPi} W_{IEMi}}{\sum_{i=1}^{m} W_{AHPi} W_{IEMi}} \tag{1}$$

where m is the number of criteria.

Step 5: Aggregate the indicators according to specific models to obtain relative capability values of each system.

The simple additive weighting method is one of the best known and the most widely used multiple attribute decision making methods [12]. The overall value of upper index in this method can be expressed as:

$$y = \sum_{i=1}^{k} w_i x_i,\ w_i \geq 0,\ i = 1,2,...,k \quad \text{and} \quad \sum_{i=1}^{k} w_i = 1 \tag{2}$$

where wi is the ith attribute weight and k is the number of attributes.

Step 6: Analysis the results according to the above calculation.

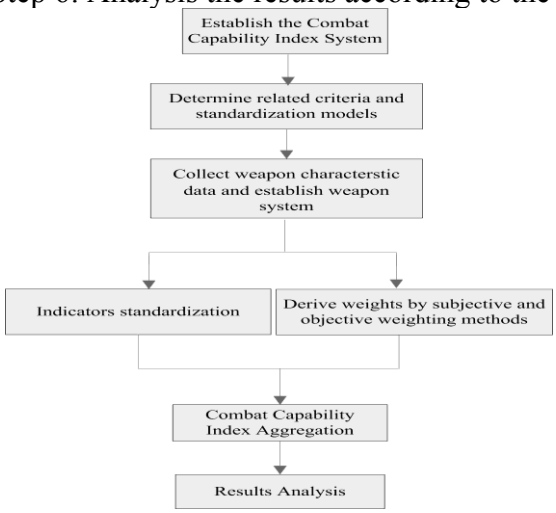

Fig 1. WSoSCGA Framework

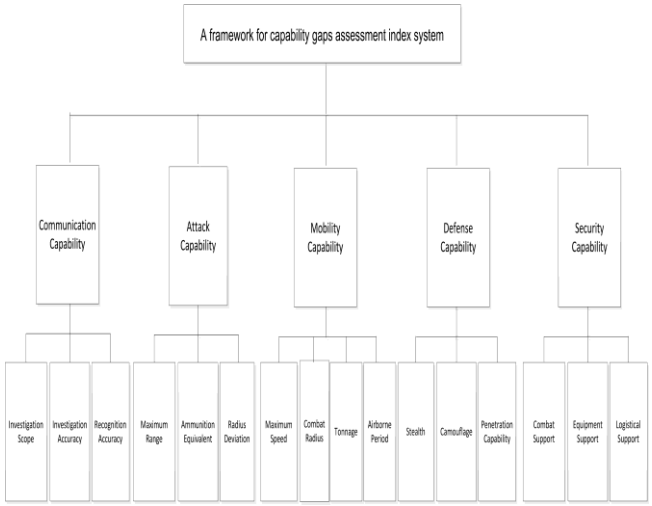

Fig 2. Capability Gaps Assessment Index System Framework

Case study

Suppose that there are two sides of combat SoS, each SoS contains a variety of different weapon categories, in which each weapon category has more than one capability and each capability can be supported by more than one weapon category.

This paper takes the best capability value among all the weapon categories as that of the system can afford. There are several following steps:

- Set up the combat capability index system
- Determine related criteria to be evaluated.
- Collect the data of both sides
- Normalize Processing and obtain synthetized weights

Table 1. Relative score on WSoS

Capability	Subcapability	Type	Friend	Enemy
Communication Capability	Investigation Scope	Benefit	1.125	1.2
	Investigation Accuracy	Benefit	1.05	1.1
	Recognition Accuracy	Cost	0.67	0.83
Attack Capability	Maximum Range	Benefit	1.2	1
	Ammunition Equivalent	Benefit	0.9	1.2
	Radius Deviation	Cost	0.8	0.67
Defense Capability	Maximum Speed	Benefit	1.1	1.1
	Combat Radius	Benefit	1.07	0.93
	Tonnage	Benefit	1.06	0.94
	Airborne Period	Benefit	1.2	1.2
Mobility Capability	Stealth	Benefit	1.5	0.8
	Camouflage	Benefit	0.8	1.2
	Penetration Capability	Benefit	1	1.67
Security Capability	Combat Support	Benefit	0.6	0.8
	Equipment Support	Benefit	0.75	1.25
	Logistical Support	Benefit	1.2	0.9

This is achieved by normalizing every element into a corresponding score value using the following formulas:

$$a_{ij} = \frac{a_{ij}}{t_{ij}}, i = 1,..., m, j = 1,...n \text{ , for benefit attribute;} \quad (3)$$

$$b_{ij} = \frac{t_{ij}}{b_{ij}}, i = 1,..., m, j = 1,...n \text{ , for cost attribute.} \quad (4)$$

The overall weights of the ith criterion can be calculated from the synthesis of the weights obtained from AHP and IEM. Take the subcriteria 3 for example:

$$w_{SYN3} = \frac{W_{AHP3}W_{IEM3}}{\sum_{i=1}^{16} W_{AHPi}W_{IEMi}} = \frac{0.0268*0.0575}{0.0568} = 0.0271 \quad (5)$$

Table 2 Weight-deriving process for criteria

Criteria	WAHP	WIEM	WSYN
Communication Capability 0.0625			
1 Investigation Scope 0.2381	0.0149	0.0920	0.0241
2 Investigation Accuracy 0.3333	0.0208	0.0690	0.0253
3 Recognition Accuracy 0.4286	0.0268	0.0575	0.0271
Attack Capability 0.1250			
4 Maximum Range 0.4118	0.0515	0.1034	0.0938
5 Ammunition Equivalent 0.2353	0.0294	0.0345	0.0179
6 Radius Deviation 0.3529	0.0441	0.0805	0.0625
Mobility Capability 0.2813			
7 Maximum Speed 0.1667	0.0469	0.0805	0.0665
8 Combat Radius 0.3333	0.0938	0.0460	0.0760
9 Tonnage 0.2778	0.0781	0.0690	0.0949
10Airborne Period 0.2222	0.0625	0.0115	0.0127
Defense Capability 0.2500			
11 Stealth 0.4737	0.1184	0.0115	0.0240
12 Camouflage 0.2105	0.0526	0.0575	0.0533
13 Penetration Capability 0.3158	0.0790	0.0920	0.1280
Security Capability 0.2813			
14 Combat Support 0.2105	0.0592	0.1034	0.1078
15 Equipment Support 0.3684	0.1036	0.0230	0.0420
16 Logistical Support 0.4211	0.1185	0.0690	0.1440

- Index Aggregation

Relative values of both sides can be obtained by aggregating the indicators. It is easy to find that our comprehensive ability amounted to 92.3% of enemy after comparison, which in a way illustrates that there still exist some gaps between each other.

$$\begin{aligned} I_1 &= \sum_{i=1}^{16} w_{SYN} a_i = 0.8911 \\ I_2 &= \sum_{i=1}^{16} w_{SYN} b_i = 0.9654 \\ I_1 / I_2 &= 0.9230 \end{aligned} \quad (6)$$

Meanwhile, we also constructed the approach with AHP weights alone to solve the same problem for comparison. The AHP model yielded a different decision result from the SYN model while our system is superior to the enemy as follows:

$$\begin{aligned} I_1 &= \sum_{i=1}^{16} w_{AHP} a_i = 1.0439 \\ I_2 &= \sum_{i=1}^{16} w_{AHP} b_i = 1.0398 \\ I_1 / I_2 &= 1.0039 \end{aligned} \quad (7)$$

The change in the outcomes when IEM weights are taken into account has shown that criteria weights found more reasonable constitute an important phase in decision-making process.

Conclusions

WSoSCGS is a hot issue in the field of military operational research, yet it lacks systematic results to date. This paper proposes a new approach based on capability ratio and model for WSoSCGS. First, all criteria are to be normalized, and then synthesized weights are obtained by using subjective weighting method and objective weighting method. And a simple additive weighting method is used to get relative capability value of each WSoS. In contrast with traditional methods, there is no need to calculate specific capability value for gaps assessment. This model can provide a new measurement and thought for WSoSCGS and analysis results can also help top-layer designers make more scientific decisions. There are many aspects involved in WSoSCGS and what is discussed in this paper is only a small part of it. Take the standardized approach for the performance parameters for example. Literatures [13] made a detailed discussion on it. As for the aggregation of the combat capability, there should be more paradigmatic relations and aggregation models to make the evaluation more close to the reality [14]. Meanwhile, quantities of equipment and relationships between different equipment are not taken into consideration in this paper. In a word, assessment related to WSoS remains to be researched.

Study on an Improved Median Filtering Algorithm

Heng Zhang, Min Gao, Hailong Ren

Missile Engineering Department , Ordnance Engineering College, Shijiazhuang 050003, China

tszhangheng@163.com

Key words: Grey histogram; Fast median filter; Noise point detection; Self-adapting threshold comparison

Abstract: Median filter is a very effective method of non-linear smoothing filtering. However, the data ordering for traditional median filtering (TMF) is very time-consuming and hardly satisfy real-time image processing. This article proposes a kind of fast median filtering algorithm based on grey histogram, the filter seeks the median through the grey histogram of mask window, not the numeric sort, which decreases the comparison times. Moreover, the update of histogram by using the overlap of mask window increases the arithmetic processing speed. Meanwhile, in the proposed algorithm, the two-level self-adapting threshold comparison, with a higher precision of detection, is used to implement the inspection of noise point and improve the image quality and increase the signal-noise ratio by processing the noise point and non-noise point respectively. The experiments by matlab simulation can prove the availability of this algorithm.

Introduction

Since the digital images usually get corrupted by impulse noise during collection, transmission and display, this will cause vague image and degraded features which will affect the subsequent image analysis directly. Therefore, image denoising has been of prime importance in image processing.

As a kind of nonlinear filtering method, median filters (MF) replace the value of a pixel by a median of the intensity levels in neighborhood of that pixel which are widely thought to be better ones for removing impulse noises since they can also preserve the edges in a corrupted image. Many different variations of median filters are proposed, including central weighted median filters (CWM)[1], switching median filters (SM)[2] , three state median filters(TSM)[3], fast median filters(FM)[4], adaptive median filters(AM)[5], and many others.

Aforementioned algorithms all have superior filtering effects in experiments. However, with the wide application of video data, the complexity of these algorithms which reduced the speed of median filter caused a great influence in speed of video data processing. The median filtering algorithm based on grey histogram [6] seeks the median through the grey histogram of mask window, not the numeric sort, which increases the arithmetic processing speed. But, the same as TMF, every pixel will be smoothed no matter whether the pixel is corrupted. This causes that the edges and some other details of image will be dimed simultaneously. Therefore, it is essential to create an improved median filter based on grey histogram.

Fast Median Filter Based on Grey Histogram

Through the grey histogram of mask window, the MF based on grey histogram finds the median through counting the cumulative frequency range from the minimum grayscale to the maximum grayscale. Overlapping character of the moving window simplified the update of grey histogram which improves the execution speed. The algorithm can be described as follows:

1. The size of image is M×N, t=M*N/2;
2. Move the mask to the beginning of a new row, sort the pixels and output the median m. Build the histogram of mask window, and then record the number n_m of pixels whose luminance is not more than m;

3. In left-most column, for the every pixel whose luminance is p_g, we do modification as
$$H[p_g] = H[p_g] - 1$$
Further, $n_m = n_m - 1$ if $H[p_g] < m$;
4. Move the mask a column to the right, In right-most column, the every pixel whose luminance is p_g, we do modification as
$$H[p_g] = H[p_g] + 1$$
Further, $n_m = n_m + 1$ if $H[p_g] < m$;
5. If $n_m = t$ go to step 9;
6. If $n_m > t$ go to step 7, we do some modifications as
$$m = m + 1$$
$$n_m = n_m + H[m]$$
until that $n_m \geq t$, and then go to step 9;
7. (Now $n_m > t$), we do some modifications as
$$m = m - 1$$
$$n_m = n_m - H[m]$$
until that $n_m \leq t$,
8. Add up the cumulative frequency n_m in the scope range from the minimum grayscale to the maximum grayscale, when $n_m \geq t$, output the gray value m;
9. If the right-most column of mask window is not the border of image, go to step 3;
10. If the bottom row of mask window is not the border of image, go to step 2;

Impulse noise only corrupts part of image pixels, but the algorithm affects every pixel which can lead to excessive filtering easily. While selective filtering will avoid unwanted filtering which means the filtering effect will be improved further.

Two-level Noise Points Detection

We can distinguish noise points from non-noise points through detection, and then process the noise point only, in other words, it can protect the non-noise points, weaken excessive filtering, and improve the performance of protection of image details.

Salt-and-pepper noise is one of the significant impulse noises that may occur in images. In an image, the gray value of salt-and-pepper noise is distributed generally on the maximum side or the minimum side [7], the luminance of noises is significantly different from its neighborhood. The probability density function of salt-and-pepper is given as

$$P(z) = \begin{cases} P_a & z = a \\ P_b & z = b \\ 0 & \text{others} \end{cases} \quad (1)$$

For the above features, the pixels whose gray value is in the scope $[0, \alpha]$ or [255-α,255] can be considered as suspected noise points. These points should be detected further, moreover, the pixels whose gray value is in the scope (α, 255-α) are kept the original gray value, where α denotes the threshold of global detection. The selection of the threshold is critical for the judgment precision, the value of α is determined mainly according to the gray value. In general, the value range of salt noises is [235,255], the value range of pepper noises is [0,20][8], therefore, the value of α is 20 usually.

The global detection of noises is based on extremum, but the details and the edges of image may be the extreme points [8]. Accordingly, it is essential to get the further local detection on the suspected noise points which can avoid false detection of noises.

The correlation between the adjacent pixels should be taken into account. The gray value of pixels is close to its neighborhood, and the difference between the corrupted pixels and the adjacent normal pixels is larger. So, on the basis of global detection, we proposed the algorithm of local detection based on threshold to divide the noise and signal effectively. However, a fixed threshold cannot adapt different kinds of images and changes of noise density. Therefore, an adaptive threshold is proposed in this paper, the equation is as

$$T=\frac{1}{N\times M}\sum_{n=\frac{1-N}{2}}^{\frac{N-1}{2}}\sum_{m=\frac{1-M}{2}}^{\frac{M-1}{2}}\left|f(i+n,j+m)-med\right|. \tag{2}$$

where $f(i,j)$ denotes the gray value of the point (i,j), med denotes the median of the mask window, the size of window is $N\times M$. For the suspected noise points, we do some modifications as

1. If $a=\left|f(i,j)-med\right|\le T$, $f(i,j)$ is considered as non-noise point, and then output the gray value of the original pixel;
2. If $a=\left|f(i,j)-med\right|>T$, $f(i,j)$ is considered as noise point, and then output the median of the mask window;

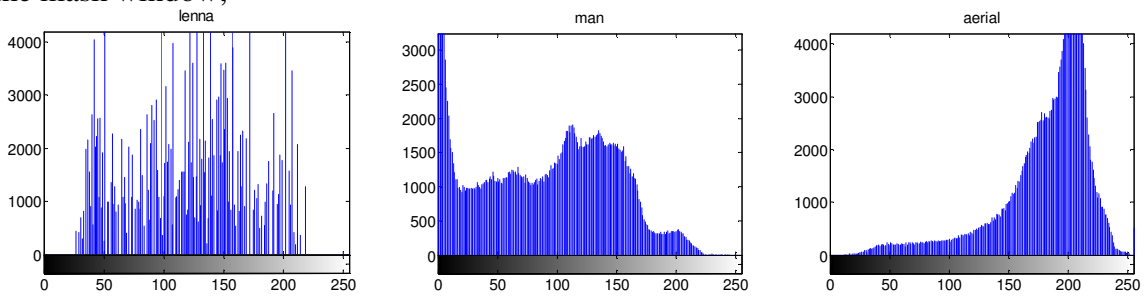

Fig. 1 The gray histogram of three images

The Simulation and Result Analysis

The effectiveness of the algorithm and the filtering effect can be validated by the simulation, the experimental platform is Matlab R2011b, and we choose three different distributions images lenna, man and aerial which are 256 grayscale, the gray histogram are given in Fig. 1.

Adding salt-and-pepper noise whose intensity is 0.2 to three images, and then process the images with the TMF (3×3), AMF and the proposed MF respectively. The results are given in Fig.2, Fig.3, Fig.4, where Fig. (a) is the original grayscale image, Fig. (b) is the image added salt-and-pepper noise, Fig. (c) is the result of TMF, Fig. (d) is the result of AMF, and Fig.(e) is the result of the proposed MF.

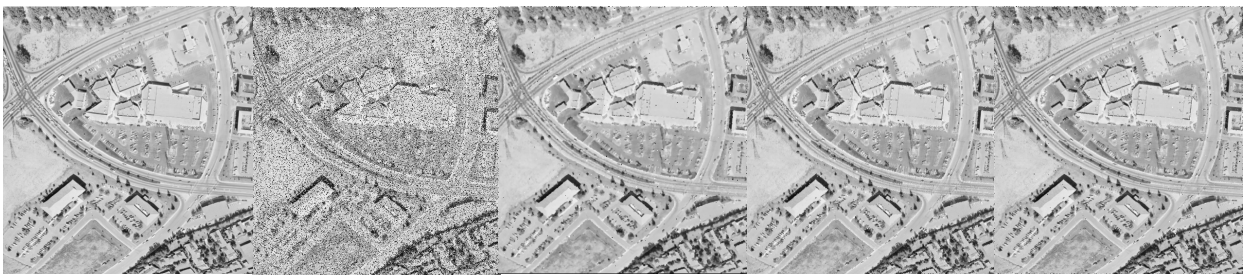
For the filtering effect, the peak signal to noise ratio (PSNR) and the mean-square error (MSE) are introduced in this paper. The equations are given in equation (3) and equation (4).

（a）Original image （b）Noisy image （c）TMF （d）AMF （e）Proposed

Fig.2 Results of different methods in restoring 20 percent corrupted image “lenna”

（a）Original image （b）Noisy image （c）TMF （d）AMF （e）Proposed

Fig.3 Results of different methods in restoring 20 percent corrupted image "man"



（a）Original image （b）Noisy image （c）TMF （d）AMF （e）Proposed

Fig.4 Results of different methods in restoring 20 percent corrupted image "aerial"

$$PSNR = 10 \times \log_{10}\left(\frac{255^2}{MSE}\right). \tag{3}$$

$$MSE = \frac{1}{m \times n}\sum_{i=1}^{m}\sum_{j=1}^{n}\left\|I(i,j) - K(i,j)\right\|^2. \tag{4}$$

where $I(i,j)$, $K(i,j)$ is the gray value of the image pre-and-post processing respectively, m and n is the row and column of the image respectively. We know that the smaller the MSE and the bigger the PSNR, the better the image quality.

On subjective visualization, the edges and details of the image processed by TMF are blurred, as shown in Fig. 2(c) of the hat, Fig. 3(c) of the hands, Fig. 4(c) of the house, the edges compare with Fig. (d) and (e) are more fuzzy, even some noise points are still exist; the places where the gray value is large or small in the image processed by AMF are little fuzzy; the image processed by the proposed MF are sharp-edged. On objective digital measure, the results are given in table 1. On speed, the proposed MF is more fast than the TMF, and is improved considerably compared with AMF; on PSNR, the proposed MF have a considerable improvement compared with the TMF, and enjoy superiority compared to AMF, the quality of image is improved obviously.

In conclusion, the execution speed of the proposed algorithm is suitable for being applied to real-time processing. And the introduction of two-level self-adapting threshold comparison advanced the precision of denoising largely, the filtering effect is much better than the TMF and AMF, and it is achieved the ideal effect of noise suppression.

Table 1 The results of three images, including PSNR, MSE and the execution time

Image	Noise(0.2)	TMF	AMF	Proposed
lenna	PSNR/dB	34.2275	38.5284	39.8839
	MSE	24.5657	9.1251	6.6786
	t/s	0.2948	0.2129	0.1503
man	PSNR/dB	33.1055	36.6123	37.1102
	MSE	30.3410	14.1856	12.6491

	t/s	0.2869	0.2142	0.1544
aerial	PSNR/dB	32.3692	35.8384	37.5912
	MSE	37.6842	16.9527	11.3229
	t/s	0.2911	0.2088	0.1477

Conclusions

In this paper, for the reason that the execution speed and filtering effect of the TMF is not ideal, we proposed a fast MF algorithm based on gray histogram with two-level self-adapting threshold noise detection. The algorithm gets the median depending on the update of histogram which improved the execution speed, the noise detection based on self-adapting threshold enhanced the ability of denoising, furthermore, it is some robust for different images. Through the result analysis and verification, the proposed algorithm is proved a kind of ideal fast MF of noise suppression.

Keywords: CSAMT;random noise; cross-correlation processing;emission signal current waveform recorder; measuring accuracy

Abstract. Controlled source audio-frequency magnetotelluric method (CSAMT) is an effective frequency domain detecting method in metallic ore exploration. In view of the weak response of a deep target signal and the serious measuring environmental noise,this paper proposes a method to deal with the noise of the CSAMT data based on the theory of cross-correlation algorithm. Emission signal current waveform recorder is designed to record signal parameters.According to cross-correlation technology, this paper uses the characteristics that correlation between emission and received signals is strong, yet the correlation between emission signals and random noise is weak, to deal with emission signals and received signals by cross-correlation ,in order to filter out random noise and other jamming signals.Field exploration test data processing contrast results show that the method can suppress noise signal, and improve the CSAMT measuring accuracy.

Introduction

CSAMT uses the controllable artificial source measuring the electromagnetic field components transmitted to the underground, which can detect a greater depth of investigation with a smaller send-receive distance to investigate. But in practical measurement,the system receives the signal that often contains noise and interference. Most of the environmental noise tested by the ground test is a wide-band random noise. This kind of noise is widely distributed in the whole frequency axis and has constant energy.At present,there are following two ways to enhance the anti-interference ability of CSAMT: One is to improve the anti-interference ability of the receiver with the advantage of being able to restrain interfering signal appropriately, but the cost is high and this method can't effectively solve the instantaneous interference or normal high-line [1]. The second way is to increase supply current or transmitted power of transmitter, the method does some satisfactory results in some places where electromagnetic interference is not serious. However it does not work in front of the powerful stray current interference and also increases the difficulty of the instrument design.

To solve these problems, this paper proposes a method that mitigates the noise signal and thus improves the noise mitigating ability of the detection system based on cross-correlation algorithm. In this method an emission signal current wave form recorder is designed,and the CSAMT measuring system emission current signal is recorded. After data processing and simulation, the cross-correlation algorithm is carried out to process the received data by using MATLAB. This method makes it possible to accurately extract the amplitude of each frequency point and phase parameters of the received data by the CSAMT. It is also able to sort out the signal to be tested that is synchronous with the reference signal in noise by improving the quality of the received data and effectively mitigating the effects of environmental noise in the course of measurement.

Emission signal current waveform recorder design overview

The current is not only a very important calculation parameter but also an important inversion calculation parameter. As the emission current frequency range is from 0.1 Hz～10 kHz, considering that the high frequency power supply current of domestic electrical method transmitter at exploration shall be greater than 2.5 A while that of low frequency shall be more than 15A in order to assure enough field strength to mitigate the interference, to solve the problem of large

dynamic range of current waveform record, in this paper the transmitting current wave form recorder with collection scope is 0.1～50 A, the frequency range of 0.1Hz～10 kHz and acquisition accuracy of 0.1 is employed.

The emission signal current waveform recorder design mainly includes: the hall current transformer, the front analog regulate acquisition circuit, AD converter and Field programmable gate array (FPGA) (Field programmable gate array, FPGA) digital logic control circuit. The emission current waveform recorder simulates the current signal emitted by the transmitter and by means of the AD converter the recorder digitalizes the signal. Then it uses FPGA as the interface circuit to receive control commands and execution them through the bus connection. Afterwards the recorder converts real-time data output by analog-digital converter and store them in the static RAM. The data is exported by USB to industrial computer hard disk for storage and subsequent processing .Emission signal current waveform recorder hardware diagram is shown in figure 1.

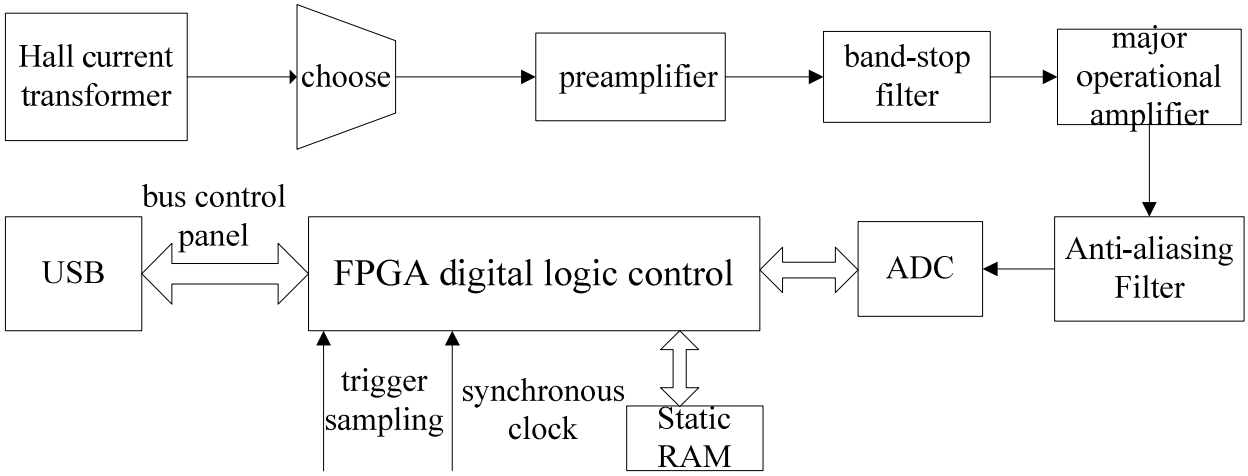

Fig. 1 The emission current waveform recorder hardware principle diagram

Front analog acquisition module

Front analog regulate acquisition circuit [2] uses multi-level programmable amplifier circuit to extend signal dynamic range. Low noise, high speed precise operational amplifier LT1007 converts current signal to voltage signal, and USES the cut-off frequency of 10 kHz low-pass filter to filter out radio frequency interference, in order to prevent the high frequency signal aliasing in the low frequency useful signal.LT1352 band-stop filter will limit the frequency interference wave of 50 Hz with passband gain of 0 db. Inverse proportional amplifier amplifies 10 times the voltage signal and through differential amplifier circuit it inhibits the common-mode signal.

Analog-to-digital conversion module

This module uses the high-speed 24 AK5394AVS type high precision analog-to-digital conversion chip as the core of acquisition card. It digitalizes the analog signals. The sampling rate of AK5394AVS is 128 times with the highest sampling rate of 216 KHZ and short circuit noise of 123 db. This module is the core part of data acquisition. Due to both high sampling rate and digits AK5394AVS requires a higher reading and writing speed demand of the USB microcontroller and takes up significantly its internal resources. Therefore in this paper the hardware interface between AK5394 and USB controller is achieved by FPGA. The AD converter is connected to the USB through a large capacity FIFO and the serial data after AD conversion is embedded in the FPGA internal high-speed FIFO [3], again within the industrial computer via USB,the serial data forms a binary data file that is stored in the hard disk for subsequent processing.

Digital logic processing module

Digital logic processing module adopts 16-bit USB controller and Cyclone Ⅲ series of FPGA device EP3C40Q240C8 control core with low consumption of Altera company. FPGA plays an important role for the bus driver.Its internal FIFO is divided into 16 low and high eight two Spaces. The FIFO has a first in first out stack structure and no address line is needed which simplifies the circuit structure. Underlying design of FPGA uses VHDL language and is solidified in the FPGA

chip. EP3C40Q240C8 realizes USB controller bus decoding function on one hand, and on the other hand it completes the timing that all the boards need. CY68013-128 AC USB controller[4] is chosen to realize the control and data transmission between industrial computer and each function module circuit. Inside it embodied the enhanced 8051 microprocessor, intelligent serial engines (SIE) and USB2.0 transceiver which improve the running speed and simplifies the development of the firmware code.

Principle of cross-correlation algorithm to suppress noise

Two way of sinusoidal signals with the same frequency , $f_1(t)$ and $f_2(t)$, which superpose the noise of $n(t)$ and $v(t)$ respectively. Random noise and the sinusoidal signals are unrelated, the random noises are unrelated,too. The expression is as follows:

$$f_1(t) = A\sin(\omega t + \varphi) + n(t), \tag{1}$$

$$f_2(t) = B\sin(\omega t + \theta) + v(t), \tag{2}$$

the cross-correlation function of $f_1(t)$ and $f_2(t)$ is

$$R_{f_1 f_2}(\tau) = \frac{1}{2\pi}\int_0^{2\pi} f_2(t) f_1(t-\tau)\,dt = \frac{AB}{2}\cos(\omega\tau + \varphi - \theta) \tag{3}$$

in the expression (3), cross-correlation function computation results only contain the amplitude and phase of sinusoidal signals with the same frequency. It can be seen that we can suppress the random noise and extract the target signals by this way. In theory, in order to facilitate calculation, we can establish two reference signals with the same frequency, $r_1(t)$ and $r_2(t)$,the amplitude of which are and the phase difference between which is 90°. Sinusoidal signal $f_1(t)$ makes cross-correlation algorithm with $r_1(t)$ and $r_2(t)$ respectively, and then we could get the amplitude and phase of measured signal.

$$A = \sqrt{R_{f_1 r_1}(0) + R^2_{f_1 r_2}(0)}, \tag{4}$$

$$\varphi = a\tan\left[R_{f_1 r_2}(0) / R_{f_1 r_1}(0)\right]. \tag{5}$$

with $R_{f1r1}(0)$:the cross-correlation function of $f_1(t)$ and $r_1(t)$;

$R_{f1r2}(0)$:the cross-correlation function of $f_1(t)$ and $r_2(t)$ [5].

Data acquisition and processing workflow design

Data collection work flow solidified in the USB microcontroller using C language.Figure 2 is for the flow chart of data collection workflow.After the system is powered on, it initializes into the best work state, and prepares the way for subsequent cross-correlation processing. Received signal files collected by peripheral store in the USB, reading its internal work allocation table, selecting the automatic frequency sweep pattern to measure multiple frequency points.In order to avoid phase difference between signal waveform and current waveform, we take GPS time synchronization acquisition technical to scan and measure the frequency points corresponding with emission signals. The received data will be transmitted into PC in CMT file format.Emission data via USB upload to PC hard disk storage, then we use XCORR cross-correlation function of MATLAB software process the emission and received data and carry on the simulation.Figure 3 is the flow chart of the data processing workflow.

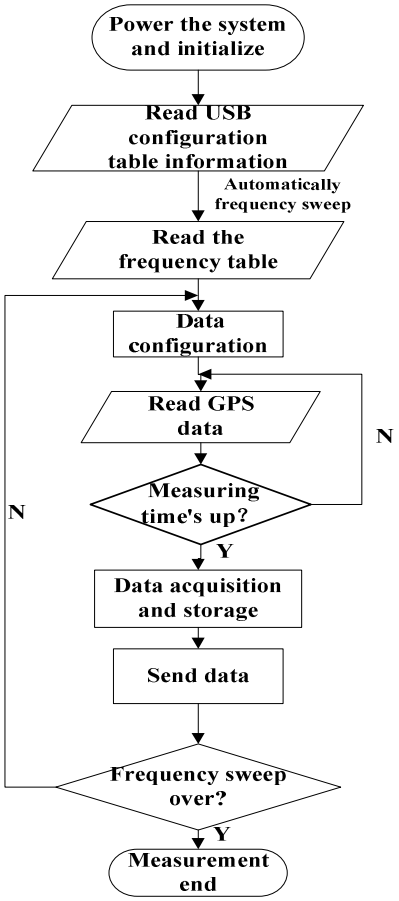

Fig2 .Flow chart of the data collection workflow

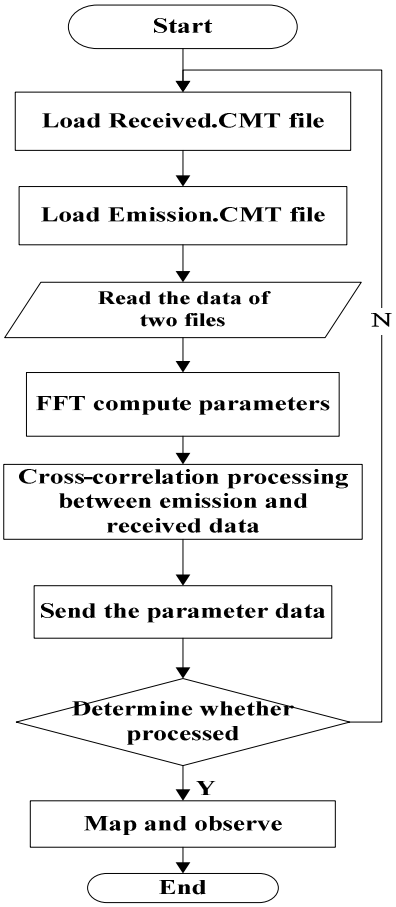

Fig 3.Flow chart of the data processing workflow

Experimental test and data processing

To test the function of the data processing of CSAMT measuring based on cross-correlation algorithm,we used it to measure the field data of Zha-cang-si in Qinghai,Guide.Figure 4 is the contrast figure of test data curves before and after cross-correlation measuring. We take part of CSAMT measuring to record the emission data, and then use the MATLAB software to establish a reasonable cross-correlation function, processing the corresponding frequency received signals, finally make it into figure. It can be seen that the original received signals contain lots of strong noise in the whole frequency axis, especially in the high frequency, which makes record curve is not smooth enough. After cross-correlation processing, random noise recorded in the received signals reduce greatly, valid data is obvious, the overall curve is smooth,and local jump point does not appear. This is because that the random noise in signal records has been suppressed through filtering and relevant algorithm processing, the rest of the received signal is valid data with weak energy.The signal-to-noise ratio has been improved.

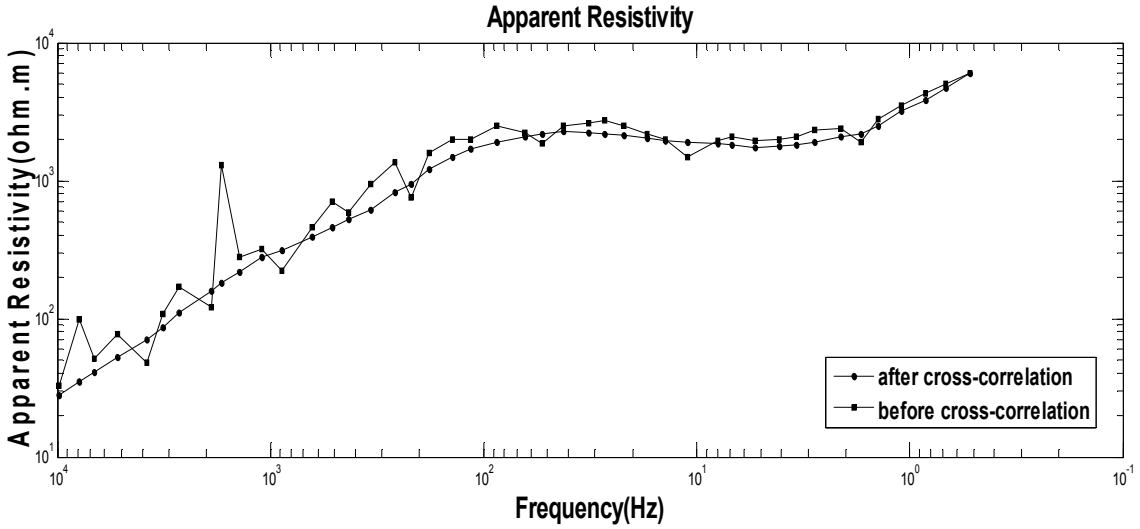

Fig.4 Before and after cross-correlation test data curves contrast figure

Conclusion

The theoretical analysis and the actual data processing results show that,cross-correlation algorithm applicated in CSAMT can weaken the random noise in received signal record from receiver and improve the signal-to-noise ratio of the received signals. In the actual operation, making use of the advantage of the characteristics of cross-correlation algorithm,we can establish reasonable cross-correlation function and parameters by MATLAB to improve the resolution of the effective signal recording.Cross-correlation algorithm has strong generalization and practicability, it not only can be used in the CSAMT method of data processing, but in all kinds of weak signal detection.

Assignment performance at Beijing South Railway Station Based on Anylogic simulation

Yanjiao Liang[a], Zhenzhou Yuan[b]

School of Traffic and Transportation, Beijing Jiaotong University, Beijing 100044, China

[a]1052543928@qq.com, [b]zzyuan@bjtu.edu.cn

Keywords: Anylogic simulation, route choice, Beijing South Railway Station.

Abstract. Assignment simulation can make a great contribution to understanding the pedestrian dynamics. Relying on the statistical data at Beijing South Railway Station, we simulate the passenger flow assigned at service establishments, provided by density parameters changing. Then, simulation result can illustrate that the passenger flow presents regular aggregation state and the density of station platform has periodic change. Furthermore, the interaction between boarding and alighting tracks and various bottlenecks are demonstrated at the platform, in which the congestion performance is applied at improving the LOS (level of service) as well as supporting passenger flow organization strategies. Finally, the proposed performances are analyzed qualitatively.

Introduction

Passengers out of subway station can generally choose three ways: stair, elevator or escalator. The large-scale integrated transport hubs have highly aggregated multiple transportation modes and often contain long-distance passenger transport mode, which allows passengers to carry more luggage. In this case, it would be more convenient to take elevators. Moreover, elevators also reflect the humanized design of the facility. It will be more widely used in large-scale integrated transport hub in the near future. However, most experts and scholars at home and abroad don't infer to elevators on study of rout choice. Therefore, the paper studies on the passengers' route choice out of station of Beijing South Railway Station by the Anylogic simulation technology, which has important and practical significance. For example, providing theoretical support for study of passenger behavior in-depth, providing theoretical basis for evaluating or improving the services efficiency of integrated transport hub and optimizing the layout of facilities and so on[1,2].

1 Overview of Beijing South Railway Station

Beijing South Railway Station is the first modern large-scale passenger transport hub in our country, which has Beijing-Tianjin intercity railway, Beijing-Shanghai high-speed railway, general speed railway, urban metro, bus, taxi and other traffic modes. It has five layers structure of three-dimensional layout. Passengers also can transfer various traffic modes although not out of station. 50% of travelers will be able to transfer with the subway in the station [3].

The paper studies on the passengers' route choice out of station of Beijing South Railway Station. Beijing South Railway Station is now opened the subway line 4 on basement level two. After getting off subway, passengers can choose stairs, elevators or escalators to enter transfer hall on basement level one. Then, there are three exits for leaving. This paper mainly analyzes passengers' route choice from the basement level two to level one. Specific analysis of flow lines is shown in Fig. 1.

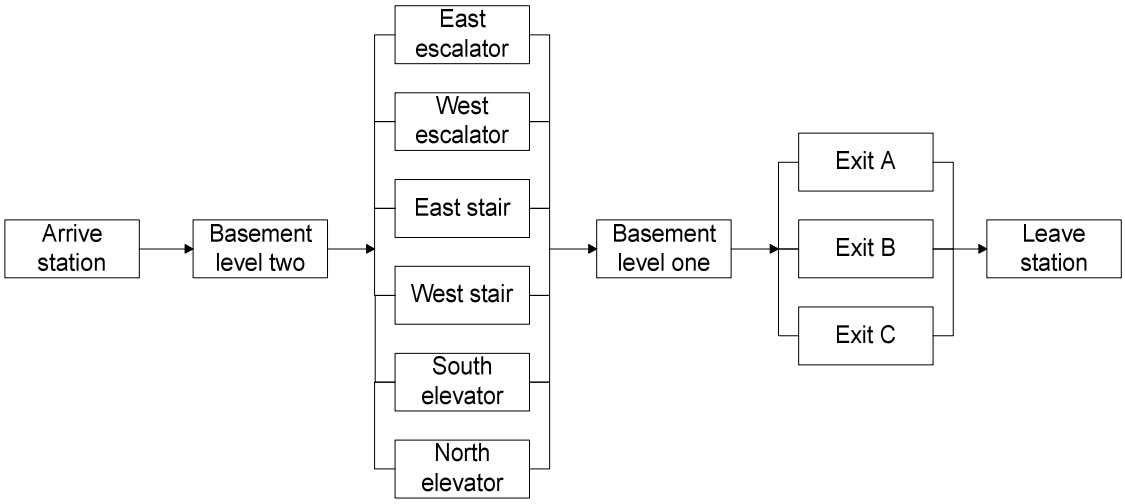

Fig. 1 Passengers' flow lines out of station of Beijing South Railway Station

2 Anylogic simulation of passenger route choice

2.1 Simulation model principle

The core algorithm of Anylogic simulation is the social force model. Social force model is continuous micro-simulation model that can give real pedestrian trail. Assumed the individuals with the ability to think and react to the surrounding environment, social force descripts subjective desire and the relationship people between people or environment. Therefore, there are three kinds of force on social model, including driving force, acting force between people and people or wall [4].

The process of establishing model is as follows [5]. Firstly, through simulation scenarios, we can determine the number and location of contour, equipment, service facilities, path and flow lines. Then, establish the different function modules. Finally, connecting each module, defining rules and selecting approaches according to the actual situation.

2.2 Establish simulation model

The simulation considers one-way flow out of subway station. Meanwhile, considers the north elevator and south elevator into an elevator. According to the practical investigation, drawing the accurate structure background of Beijing South Railway Station and importing into Anylogic software interface. Closed polylines express walls, equipment covers and other area which pedestrians can't pass through. Simple lines indicate service facilities or entrances. Simulation environment is shown in Fig. 2.

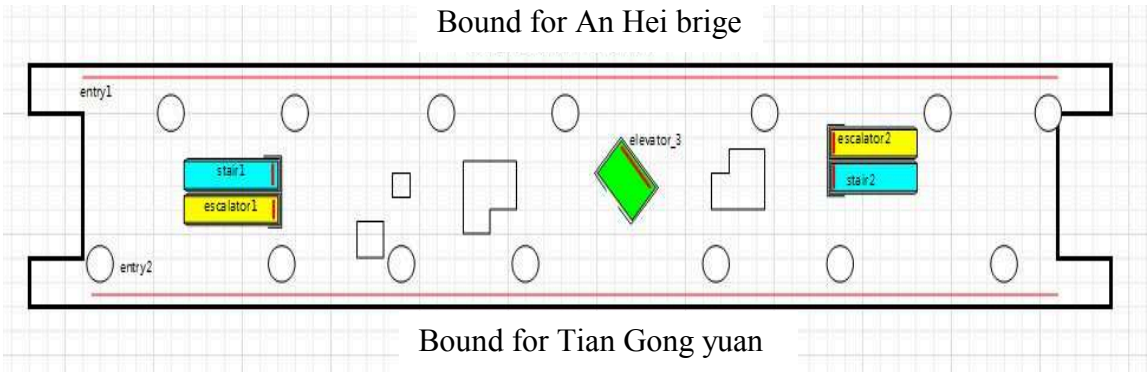

Fig. 2 Simulation environment

Building functional modules, selecting rules and determining flow lines. Passengers' route choice is an input-services-output process. PedSource is pedestrian starting module. PedSelectOutput is choice module. PedGoto is direction controlling module. PedSink is pedestrian disappearing module.

PedConfiguration is pedestrian property module, which is used to define the basic properties of the pedestrian. PedGroud defines the scope of the wall. PedArea defines the fixed area of facility. The flowchart of passengers' route choice is as Fig. 3 [6].

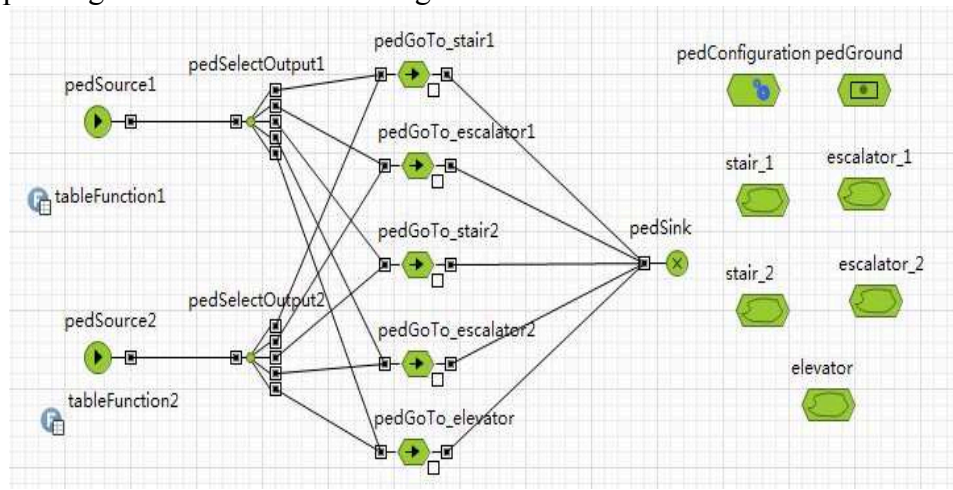

Fig. 3 Simulation model flowchart

Setting attributes parameters for each module in the flowchart. Such as, shape, color, capacity of facilities, choice proportion and so on. There are four main types of variables and three main types of modules [7].

(1)Setting PedSource object parameter is mainly for the arrival pattern of passengers. TableFunction can represent the reach interval of train. Based on actual data, we can establish the periodic train schedule. Moreover, set step speed from 0.8 to 1.5 meter per second, which is from actual research. In order to distinguish the direction of passengers, set purple for passengers bounding for An Hei brige while blue bounding for Tian Gong yuan.

(2)Setting PedSelectOutput object parameter is mainly for choice proportion out of station based on actual data.The choice proportion bounding for An Hei brige is as follows.stair1:escalator1:stair2: escalator2:elevator=0.06:0.51:0.05:0.22:0.16 while the choice proportion bounding for Tian Gong yuan: 0.1:0.38:0.08:0.35:0.09.

(3)Setting PedGoto object parameter is mainly for stage goal of passengers. The direction selected by passengers needs to be set in the simulation environment. The control for pedestrians in simulation is very realistic. Pedestrians will choose the shortest path from the initial target to the final target and circumvent the obstacle flexibly. That's to say, simulation matches well with actual pedestrian movement. However, there are many obstacles in the subway platform of Beijing South Railway Station. Once no route guidance, the large-scale jam is easy to happen. So we set route guidance according to the actual situation.

(4)Setting PedArea object parameter is mainly for passenger throughput of service facilities. Based on relevant references and practical research, the operation speed of escalator is 0.5 meter per second, corresponding to the maximum capacity of 8100 people per hour. The stair of Beijing South Railway Station is mixed direction and 2.5 meters width. Refer to urban rail transit design specifications, there are mixed capacity of 3200 persons per hour on one meter width. So the maximum stair capacity of Beijing South Railway Station is 8000 people per hour. Because of more loads, the elevator deadweight of Beijing South Railway Station is about ten persons and it will take 17 seconds to operation from basement level two to level one. Therefore, the maximum capacity of elevators is approximately 1200 persons per hour by calculating roughly.

We have to designate areas in front of stairs, escalators and elevators to collect flow data and calculate density. Then, add density sketch to observe simulation results intuitively.

2.3 Analyze simulation results

After running simulation [8], we can get passenger flow of five areas. After that, calculate density according to areas. The results are shown in Table 1, Fig. 4, Fig. 5 and Fig. 6.

Table 1 Density statistics after simulation

area	average density（p/m^2）		
	train arrive (bound for An Hei brige)	train arrive (bound for Tian Gong yuan)	two trains arrive at the same time
escalator 1	0.79	0.88	1.32
escalator 2	0.52	0.61	0.98
stair1	0.13	0.17	0.22
stair2	0.11	0.14	0.21
elevator	0.25	0.19	0.28

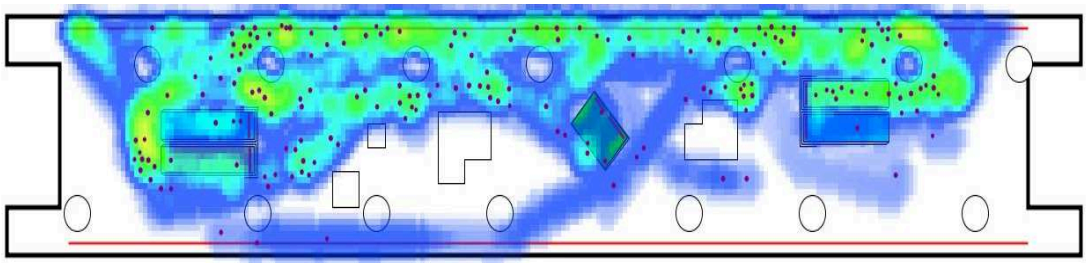

Fig. 4 Density sketch when train arrive (Bound for An Hei brige)

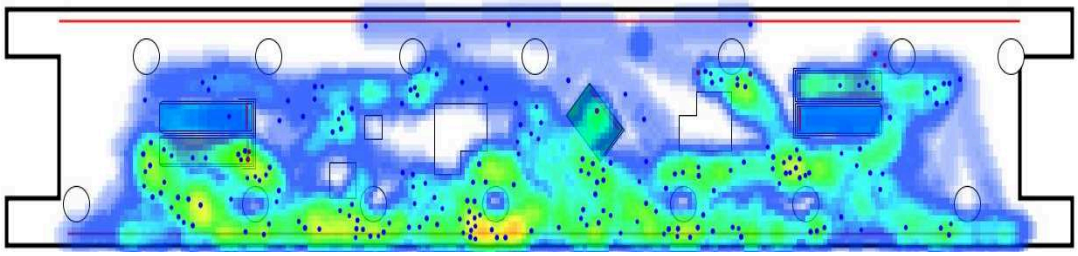

Fig. 5 Density sketch when train arrive (Bound for Tian Gong yuan)

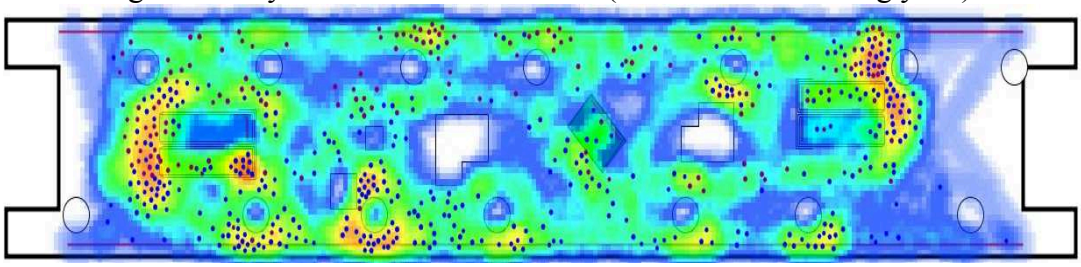

Fig. 6 Density sketch when two trains arrive

(1) Passenger flow presents regular aggregation state and the density of station platform has periodic change. As trains arrive, the station platform produces a large number of flows in just a few seconds. It is the maximum passenger density when two trains arrive at the same time.

(2) As shown on table and figure, density increases obviously and pedestrians queue up in front of escalators. There no queue in front of stair while some passengers wait for elevators, which is consistent with actual situation.

(3) The average density of west escalator is higher than east escalator. So the utilization rate of west escalator is higher than east escalator. Moreover, Escalators are close to the train bounding for Tian Gong yuan. Passenger flow which produces from the train bounding for Tian Gong yuan is larger number than other direction.

(4) The simulation only considers unidirectional flow and don't considers influence of mixed flow. Therefore, the statistical density of stairs and elevators are smaller than actual situation.

(5) The train bounding for An Hei brige produces less flow. However, it has high departure frequency and low departure interval. In order to evacuate passengers rapidly, the measure that increasing appropriately departure interval bounding for An Hei brige and reducing departure interval bounding for Tian Gong yuan can be taken.

(6) There is a common phenomenon that some passengers who load a lot don't choose elevator. The reason is that they don't know the existence of elevators or don't know the location of elevators. Strengthening publicity of elevators and encouraging passengers who load a lot to take elevators, which will reduce queuing delay of escalators.

(7) According to the simulation results, there are jams on some of obstacles. For example, the monitoring room is near the door, there are jams between the monitoring room with the door. We can move the monitoring room to middle position.

3 Conclusions and prospects

In this paper, with the aid of Anylogic software, the author achieves the current simulation of Beijing South Railway Station out subway station passengers and gets the passenger flow and density parameters. Then, fund that the passenger flow presents regular aggregation state and the density of station platform have periodic change. Moreover, according to the simulation results, analyzing the reason of rout choice and putting some pieces of advice to improve the service level of facilities.

Although the article makes some achievement, there are some deficiencies. For example, applying tablefunction to simulate arrival of train. However, tablefunction can't reflect the real condition accurately. Meanwhile, the simulation only considers unidirectional flow and don't considers influence of mixed flow. Research will focus on making simulation close to the real condition in the future.

Keywords: ECOM, storm surge, extre water level, Bohai Sea

Abstract: In this paper, a numerical model of the coupling between astronomical tide and storm surge based on hydraulic model for estuary and coast (ECOM) is confirmed to be suitable for simulation of stormsurge in the Bohai Sea. The spatial distribution of extreme water level and storm current field caused by typhoons in October 2003 are simulated.It shows that extreme water level in deep water are smaller than shallow water and the spatial distribution of extreme water level is influenced by topography.Flow filed in Bohai Sea waters takes on an fluctuation in flow field, compensatory flow and other obvious features during storm surge, compared storm surge with astronomical tide, which is a significant difference in flow filed.

1 Introduction

With a long coastline, China is one of Pacific Rim countries, which is frequently-stricken by storm surge, from south to north, leaving impact on different areas at various degrees. A great loss has been brought to Bohai Bay, where alone has been attacked for 16 times during 1985 to 2013. Therefore, research on disasters caused by storm-surge has been a matter of top priority.

The special terrain characteristic in the Bohai Sea is advantageous to form storm surge. The intense and lasting easterly wind was the important factor. The simulation of several storm surge processes is carried out in the Bohai Bay and shows that the strong easterly wind is the major reason which causes maximum storm surge in the Bohai Bay [1-2]. Extratropical cyclone induces distinct water level set-up/down and makes remarkable changes on flow velocity and direction of local sea area[3].

Based on ECOM model, this article takes typhoon pressure-field and wind field as input conditions, to create a numerical value forecast mode applicable to storm surge occurred along Bohai Sea waters, and to carry out analog studies on numerical value of storm surge in Bohai Sea waters.

2 Numerical model and setting

2.1 The introduction of ECOM

The model for shallow water environments – rivers, bays, estuaries and the coastal ocean and reservoirs and lakes- named ECOM [4].It consists of several modules which are hydrodynamic module, wind induced wave module, heat flux module and particle tracking module.

The prognostic variables are the three components of velocity,temperature, salinity, turbulence kinetic energy, and turbulence macroscale. The momentum equations are nonlinear and incorporate avariable Coriolis parameter. The vertical mixing coefficients are obtained by appealing to a second order turbulence closure scheme. ECOM uses an orthogonal curvilinear coordinate system and sigma coordinate system, greatly increasing model efficiency in treating irregularly shaped coastlines and in meeting requirements for high resolution at desired locations. Many thermodynamic processes are taken into account. Horizontal finite difference is explicit scheme in time but vertical direction is implicit scheme. The later has a much less stringent time step and relatively rough resolution near the surface and bottom. It has fine vertical resolution when the horizontal explicit scheme and vertical implicit scheme is chosen in internal hydrodynamics option. Operator splitting is used in calculation

and make the calculation flexible, simply, stable, precision.The detailed basic theory of ECOM can be seen in Blumberg (1996) and would not be given here.

2.2 The setting of model

To avoid the impact of boundary condition on model simulation, the East China Sea is simulated as a large scale computing area, with 0.05′×0.05′grid, covering range 33°46′32.86″N~36°11′28.37″N, 120°31′33.65″E ~126°33′18.71″E. Barotropic assumption is applied to numerical simulation, that is, temperature and salinity is assumed to be constant and heat flux, salt flux and wind flied is zero.The elevation data of terrain is provided by naval guarantee department of PLA (the People's Liberation Army of China), which are adjusted on domain. There are 2s steps for mode. In the Bohai Sea, the bottom friction coefficient is 0.001, and 0.0023 in the Yellow Sea and the East Sea,which are based on experiment and previous numerical experiments[5].The elevations and phases of M2, S2, O1, P1 and K1 tides at the open boundaries with the harmonic constants of the five tides are taken from the NAO.99b tidal prediction system.The bathymetry data for the computing grid is obtained through interpolation with navigational chart in the Bohai Bay with high resolution 0.05′×0.05′.

2.3 Wind and pressure field

Calculation of the FBM model of the pressure field is realized by Fujita formula and Gaoqiao formula below :

$$P_r = (P_\infty - P_0)\left(1 - \frac{1}{\sqrt{1+2(r^2/R^2)}}\right) + P_0 \quad (0 \le r \le 2R) \tag{1}$$

$$P_r = (P_\infty - P_0)\left(1 - \frac{1}{\sqrt{1+r/R}}\right) + P_0 \quad (2R \le r \le \infty) \tag{2}$$

Where P_0 = center pressure of typhoon. P_∞ = periphery pressure.R = radial maximum wind, P_r = the typhoon pressure located r. r= the distance from the center of the center of typhoo.

Wind field of typhoon is calculated by two vector superposition field respectively which are relative to the center of typhoon wind field and basic wind field.

Relative to the center of typhoon wind field is calculated by:

$$V_g = -\frac{1}{2}fr + \left[\left(\frac{1}{2}fr\right)^2 + \frac{r}{\rho_a}\frac{\partial p}{\partial r}\right]^{\frac{1}{2}} \tag{3}$$

Where V_g is the gradient wind,f is the Coriolis force coefficient, ρ_a is air density.

i

Basic wind field is calculated by:

$$\vec{V}_{sm} = V_x \exp\left(-\frac{\pi}{4}\frac{|r-R|}{R}\right)\vec{i} + V_y \exp\left(-\frac{\pi}{4}\frac{|r-R|}{R}\right)\vec{j} \tag{4}$$

Where V_x, V_y is the velocity of center of the typhoon in the X and Y direction.

3 Numerical simulations and results

3.1 Analysis of process of increase and decrease in water lever during storm surge

From each water level process curve（Fig. 1） and seen from Bohai Bay and other bays, periodical fluctuation of Bohai Bay storm tidal level and surface mean value, which decreased followed by increase, indicates that, during the period of cold wave & strong wind in October, 2013, storm-surge water level is affected by periodical fluctuation and wind field. Rise and fall in water volume varies with different waters along Bohai Sea's during storm surge: decreased followed by increase at Liaodong Bay and Bohai Bay, with maximal 201cm rise and maximal 513cm fall at Liaodong Bay, 218cm and 220cm respectively at Bohai Bay. While, at Laizhou Bay, the tendency is decrease followed by increase, then another decreased followed by increase, with maximal 188cm rise and maximal 220cm fall respectively. Seen from the moment when maximal value appeared, the maximal increase turns up as Liaodong Bay, Bohai Bay and Laizhou Bay in sequence, so does the maximal decrease.

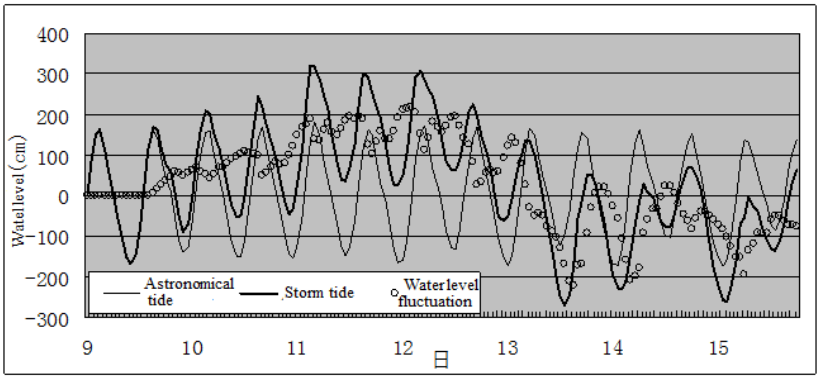

Fig. 1 Water level process curve during storm surge in Bohai Sea

3.2 Horizontal distribution of storm-surge water increase and decrease

From the isopleth map of increase and decrease in water lever during storm surge（Fig. 2）, it indicates that water level at Bohai Sea and North Yellow Sea goes up and down dramatically during cold wave and strong wind, which imposes a large impact on the waters. Water level increase in Bohai Sea waters caused by cold wave and strong wind is much higher than that of Yellow Sea waters. Besides, increase in water level at inshore shallows is obviously higher than that of deepwater. Therefore, the rise brought by storm surge mainly happens at Bohai Sea's shallow waters. The openness of waters decides the tendency of isopleth map of water level rise. In the middle waters of Bohai Sea and other wide waters of North Yellow Sea, distribution of water rise isoline takes on NE-SW inclination, basically vertical with wind direction of cold wave and strong wind. The tendency of water rise isoline at Bohai Bay, Liaodong Bay and Laizhou Bay and top pf bay coastline distribute parallelly. Affected by Northern inclination, seen from water rise value at Bohai Sea's bays, it shows that Bohai Bay takes the maximal rise, Laizhou Bay next and the last is Liaodong Bay.

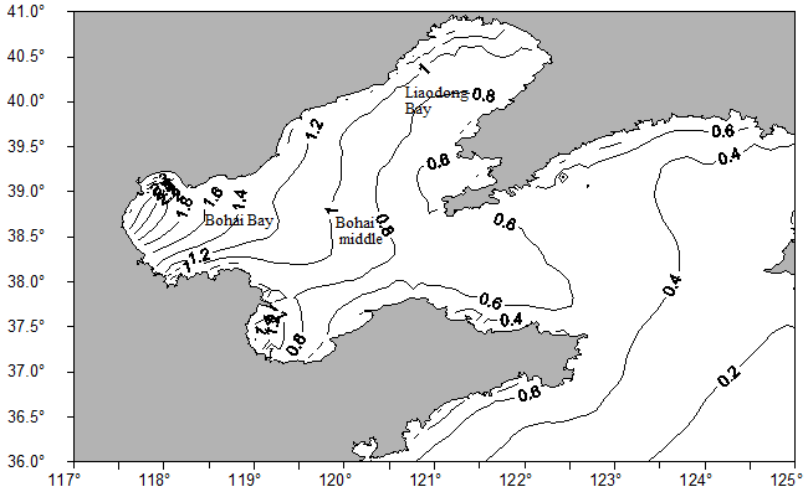

Fig. 2 The isopleth map of increase and decrease in water lever during storm surge（m）

3.3. Features of storm-surge's tidal flow filed

During storm surge, at Bohai Sea, North Yellow Sea, and Baohai Sea's bays, different waters are influenced by northern strong wind, coastline water depth and diverse terrains at different degrees, with a varying characteristics at flow filed pattern（Fig. 3）, mainly featured in: influenced by northern cold wave and strong wind, flow direction at the top of Liaodong Bay is offshore, and the flow rate is obviously rapid at this area. At the inshore area of eastern and western bay, the rotatability of the ocean current in the middle of the bay is strengthened, with prominent unsteadiness in flow rate and flow direction. Influenced by cold wave and strong wind, flow direction at southern shore of Baohai Bay is constantly southward or eastward, with few alteration in flow rate, but faster than flow rate of astronomical tide in average. The flow rate at central and northern waters of Bohai Bay becomes distinctly faster, especially at the northern shore. Correspondingly, the rotatability of flow direction is enhanced. As a whole, the flow filed pattern of Bohai Bay is counter-clockwise circulation, that is,

southern ocean current flows out, while northern ocean current is compensatory inflow. In the middle waters of Bohai Sea, ocean current is not rotative any more, but maintains flow direction between southward and eastward, that is, toward Bohai Sea straits, at a relatively rapid flow rate. In a word, under the mutual influence of astronomical tide and cold wave, flow filed at Bohai Sea waters takes on an fluctuation in flow field, compensatory flow and other obvious features during storm surge, compared storm surge with astronomical tide, which is a significant difference in flow filed.

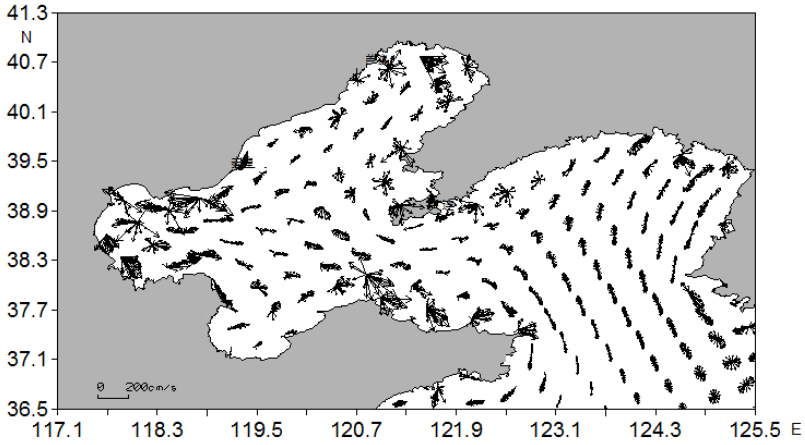

Fig. 3 Flow field during storm surge

4 Conclutions

The results indicated that extreme water level in deep water are smaller than shallow water and the spatial distribution of extreme water level is influenced by topography.Flow filed in Bohai Sea waters takes on an fluctuation in flow field, compensatory flow and other obvious features during storm surge, compared storm surge with astronomical tide, which is a significant difference in flow filed.

Keywords: domain compound concept; concept extraction; multilevel filter; location label; POS analysis.

Abstract. Identification and extraction in domain compound concept is the basis of the domain text information processing. This paper builds a multilevel filter extraction model by fusing the thought of statistics and language rule. Firstly, the extraction model screening out domain atomic concept set by using method of improved TF-IDF. We secondly build a space combination rule, screening out initial domain compound concept set. Ultimately we screening out finally domain compound concept set by using POS rules template matching via POS analysis. Experiments show that this method can effectively identify and extract domain compound concept and F-measure has reached 83.9%.

1 Introduction

Identification and extraction in domain compound concept [1] is the basis of the domain text information processing, it has important significance on domain ontology's construction and application, text information retrieval and text mining. With the social progress, the development of science and technology, new concepts emerge in an endless stream, especially for the compound concept in each field. These domain compound concepts generally are noun phrases which are formed by domain atomic concepts or words, they refer to more precise information for domain concepts. The existing word segmentation system can't recognize the new domain compound concept, so it can't meet the needs of practical applications. Therefore, automatic extraction in domain compound concept is needed.

The method based on rules [2] and methods based on corpus statistics [3] are the two main methods of extraction of concepts. The method based on rules identifies new concept by tagging dictionary and phrases. Its main idea which is based on the linguistic theories and knowledge is to develop a series of commonness and individuality of rules. The method based on rules can extract new concepts by high quality, but those rules are generally for specific field, so it has poor flexibility. The methods based on corpus statistics don't need syntactic and semantic information. They don't confine to a certain field and don't rely on any other resources, but they have strong versatility. The performance of methods based on corpus statistics depends on the corpus' scale and word's frequency information. Some candidate concepts which have low frequency may be right concepts, while some other candidate concepts which have high frequency may not be right. So, the method based on corpus statistics is difficult to guarantee the quality of extraction.

This paper builds a multilevel filter extraction model by fusing the thought of statistics and language rule, and constructs a compound concept extraction system based on multilevel filter. Then we evaluating the system by calculating it's accurate rate, recall rate and F value.

2 Multilevel filter extraction model

The multilevel filter extraction model is shown in figure 1.

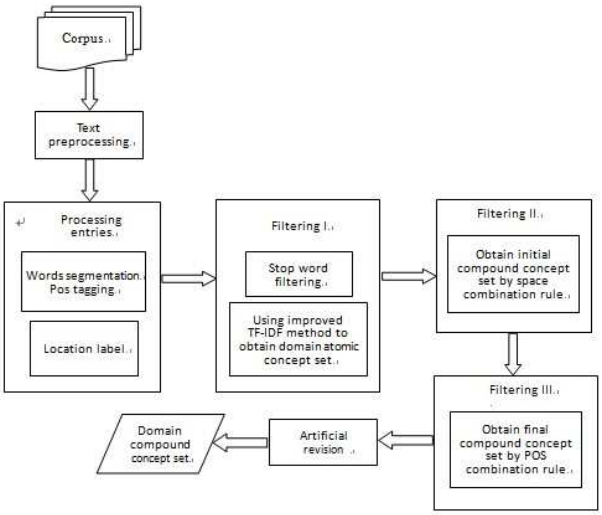

Figure 1 Multilevel filter extraction model

From figure 1, we know that the model contains three main filtration stages. In the first filtering stage, the extraction model screening out domain atomic concept set by using method of improved TF-IDF. In the second filtering stage, we build a space combination rule, screening out initial domain compound concept set. And in last filtering stage, we screening out finally domain compound concept set by using POS rules template matching via POS analysis.

3 Implementation processes

This paper is to extract the domain compound concept according to the multilevel filter extraction model. The extraction process and the corresponding algorithm will be described in the following contents in detail.

Text preprocessing. At this stage, we will remove images and formulas from texts, and only left words and punctuation. Then, we will convert them into TXT format.

Words segmentation and POS tagging. Nowadays, the ICTCLAS segmentation system which developed by Chinese Academy of Sciences has been widely used in Chinese language processing. So, we use ICTCLAS segmentation system for word segmentation processing in this paper.

The results of POS tagging are as follows:

$$\mathrm{POS}\ (c_a) = \$_i \tag{1}$$

$\$_i \in$ {n(noun), v(verb), a(adjective), b(Distinguishing words), h(prefix), k(suffix), l(idioms), s(place), z(status), t(time), f(direction), r(pronoun), m(numeral), q(classifier), d(adverb), p(preposition), c(conjunction), u(auxiliary), e(interjection), y(tone), o(onomatopoeia), x(string), w(punctuation)}.

Add location label for entry. Location label reflects the specific location information of each entry. After words segmentation and POS tagging, we need add location label for each entry. In case of punctuation, then the sequence number of entry which is behind the punctuation will automatically plus 1.

The results of location tagging are as follows:

$$\mathrm{P}(c_a) = (d_k, s_i, n_j) \tag{2}$$

In formula (2), d_k shows which document entry c_a is in, and s_i shows which sentence c_a is in, and n_i shows c_a's sequence number in sentence s_i.

Filtering out stop word. Chinese text often contains some high frequency words which don't have relationship with field, and it also contains some words which can't be formed into combined words. Those words don't represent any field knowledge, and also have little influence on word-building. We call those words stop words, and we should filter out them. Through filtering out stop word, we can improve accuracy of atomic domain concepts extraction. Especially when corpus' scale is huge, it can obviously reduce the calculation of domain concepts extraction and improve the running speed of the system.

Atomic concept filtering based on improved TF-IDF formula. The traditional TF-IDF [4] formula is a weighted statistical technique which is usually used in information retrieval, we can use it to evaluate the important degree for a corpus or a file set. The importance of word is increase proportional to the times of its appearance in document, but at the same time it is inversely proportional to the frequency of its appearance in corpus. But the traditional TF-IDF formula does not consider the effect of the word length on weight. So this paper uses improved TF-IDF formula to calculate the weight of entries.

The improved TF-IDF formula is as follows:

$$w_i = \sum_{k=1}^{n} \frac{TF_{ik} \times IDF}{\sqrt{\sum_{k=1}^{n} (TF_{ik})^2 \times (IDF)^2}} \tag{3}$$

$$IDF = \mathrm{lb}\left(\frac{N}{n_k} + 0.01\right) \tag{4}$$

$$W_i = \mathrm{lb}(L) \times w_i \tag{5}$$

TF refers to Term Frequency, and IDF refers to Inverse Document Frequency. IDF think that if the numbers of document which contains ca is less, then IDF is bigger, and ca has good ability of distinguishing categories. L refers to entry's length, w_i refers to weight which does not consider the length of entry, and Wi refers to weight which consider the length of entry. In this paper, we can use improved TF-IDF formula to screen out the atomic domain concept.

Compound concept filtering based on space combination rule. *Definition 1*(*space combination rule of compound concept*) space combination rule of compound concept contains the following two contents: (1) the atomic concepts are in accordance with the existing adjacent order in the same sentence, and they are combined into a atomic concept string A_i; (2) compound concept C_m is the substring of atomic concept string A_i. *Definition 2* (*the longest binding rule*) we assume that there is a string A_i which contains entry c_a, A_i=…$c_{a-1}c_ac_{a+1}$…, and the longest binding rule for c_a satisfies the following two contents: (1) if there is a adjacent entry c_{a-1} in front of c_a, we combine c_{a-1} and c_a , until there are no other adjacent entries in front of them. (2) if there is a adjacent entry c_{a+1} behind c_a, we combine c_{a+1} and c_a , until there are no other adjacent entries behind them. After adding location label, each atomic concept has its own location label P (d_k , s_i, n_j), then we can screen out them by space combination rule. The specific steps are as follows. Step1: each entry has a location label P (d_k , s_i, n_j),and for the entries which are in the same document and in the same sentence, the values of their d_k and s_i are the same, too. If their n_j have adjacent sequence number, we combine those adjacent atomic domain concepts to a domain concept string A_i, and A_i is marked as A_i= $c_1c_2...c_n$(according to the past experience, the value of n is a positive integer between 2-7). Step2:for every atomic entry c_a(1≤a≤n;n∈ N), find out all combined entries which are led by c_a with a single entry for incremental step. We put them into a set A_m, and call its item C_m which may be a compound concept. Step3: travel through every sentence s_i, and count the frequency of C_m. Step4: set a threshold value, and select out those C_m which's frequency value bigger than the threshold vale, and add them into a initial compound concept set. Step5: for items C_m which contain c_a and in the same sentence, we screen out final item C_m by the longest combining rule. And then we can update the initial compound concept set.

Compound concept filtering based on POS combination rule. Compound concept generally consists of nouns, verbs, Nominalization of verbs and adjectives. Most of them are combined by only two or three words, and they usually have specific POS combination rules. According to the characteristic of compound concept and test data, this paper has proposed POS rule templates for those compound concepts which are combined by two words and three words in computer field. The POS rule templates are shown in table 1 and table 2.

Table1 POS rule template for two words

Pos rule template
a + n
v + n
n + n
n + v
d + v

Table2 POS rule template for three words

Pos rule template	
n + n + n	v + v + n
n + n + v	v + n+ n
n + v + n	a + n + v
n + c + n	a + v + n
v + n + v	b + v + n

Most of domain compound concept can be screen out by those POS rule template, but we can't find out every POS combination rule of compound concept at a time, so when we find other POS combination rules in the future, we can add them in POS rule template.

4 The experimental analysis

The evaluation indexes of compound concept extraction. The precision rate and recall rate can reflect the quality of compound concept extraction, so we use them as evaluation indexes. In addition, we also use F value as evaluation index.

$$\text{precision rate:} \quad p = \frac{\text{correct number of extracted compound concept}}{\text{total number of extracted compound concept}} \times 100\% \tag{6}$$

$$\text{recall rate:} \quad r = \frac{\text{correct number of extracted compound concept}}{\text{total number of compound concept in document set}} \times 100\% \tag{7}$$

$$\text{F value:} \quad F = \frac{2pr}{p+r} \tag{8}$$

The experimental result. In order to validate the effectiveness of compound concept extraction by our method, other two representative methods are compared. One is the Chinese term extraction method based on mutual information [5], marked as M1; another is the new word identification method based on word internal model [6], marked as M2; and our method marked as M0. We download 100 articles which are related to computer field from Wanfang database, and use them as the corpus of domain compound concept extraction experiment. Those three methods use the same corpus and set the same threshold. In the experiment, we obtain compound concept set related to computer field by manually. According to the experimental design, the results of compound concepts extraction by those three methods are shown in table 3.

Table 3 Extraction results by three methods

Method category	The total number of compound concepts	The number of extraction	The correct number	precision rate(%)	recall rate(%)	F value(%)
M0	535	506	437	86.4	81.7	83.9
M1	535	576	418	72.5	78.2	75.2
M2	535	548	360	65.7	67.3	66.5

The experimental results show that, the precision rate, recall rate and F value of M0 are higher than those of M1and M2, so M0 has better extraction effect than M1and M2. The main reason is that M0 use POS rule template which for two and three words to filter after entry co-occurrence statistics extracting. The factors which influence extraction on M1are mainly two categories: 1) The internal bonding strength. For a string which is combined by two words and contains a basic word, it has a low internal bonding strength, so it can not be extracted out. 2) Wrong segmentation in term selection stage. The factors which influence extraction on M2 are mainly two categories: 1) The search of repeated string. There are many garbage strings in repeated string, and we have not enough methods and POS rules to filter them. 2) It is difficult to set the threshold of weighted value. The factors which influence extraction on M0 are also mainly two categories:1)Some words which are combined to compound concept are belong to stop word, so we may filter them by stop word table, and thus we can not get a complete compound concept. 2) We can not find out every POS combination rule. When we meet a compound concept, and its POS combination rule is not included in the template, then we may filter it. Thus, we need add that new rule into template.

Summary

This paper builds a multilevel filter extraction model by fusing the thought of statistics and language rule. In the model, we present the space combination rule and POS combination rule for two and three words. Through those two innovations, we improved the accuracy of compound concept extraction. And the experiment has achieved good results. However, the extraction of compound concept remains to be improved. For example, some stop word is a part of compound concept, if we can extract out those compound concepts , then we can improve the recall rate.

Keywords: cloudstack, hybrid cloud, virtualization technology

Abstract. While setting up the cloud computing platform by using OpenStack, there were some disadvantages such as very tedious operating steps and low efficiency. In this paper, we put forward a design and realization method based on CloudStack hybrid cloud computing platform. Firstly, we used CloudStack as tool to set up two independent cloud platforms, one of them was called public cloud and the other one private cloud. Then virtualization technology and a shared resource classification method discussed in this paper were performed to set up two virtual sub-servers on the main server and operate the cloud platform already established on it. Finally, we gave the two platforms corresponding authority, thus the hybrid cloud platform was established. This method was easy to set up and could reduce the cost effectively, therefore, it was very practical.

Introduction

Cloud computing is a computing mode by which the user or the application system can customize services, resources and applications without understanding the means of realization [1,2]. It is also a kind of new business computing model which offers the IT resources, data and applications as services for users via internet. Cloud computing solutions give a methodology of infrastructure management, which supplies highly virtualized resource for users dynamically. The network who provides resources is called “cloud”. The resources in it are considered to be infinite extent by users and can be obtained, used as needed, extended and paid for use at any time. Normally, this character is called as using IT infrastructure like water or electricity.

In accordance to the deployment patterns and the scope of the service object of the cloud, we can divide the cloud into three types: public cloud, private cloud and hybrid cloud.

The public cloud is shared by several enterprises and users, although it has some advantages such as low price and elastic strategy, however, there also exists safety problems because the data storage location of the public cloud is not in the enterprise. The private cloud can provide services only to the inner-enterprise users so that people can control the data security and service quality effectively. However, the hybrid cloud combines the public cloud and the private cloud so that users can both partly possess and share the resources through a controllable method. Therefore, more commercial value will be created by setting up the hybrid cloud.

At this stage, the main tools for setting up cloud computing are OpenStack, CloudStack and Eucalyptus. According to paper [2], [3] and [4], researchers have designed and developed cloud computing platform and applied it to management, education and experiment. OpenStack has many advantages such as a mature platform, an easier operating process and is convenient to use. However, compared to CloudStack, deployment process of OpenStack is very complicated and it also needs a huge research and development team and higher level developers.

This paper came up with a method of constructing the hybrid cloud platform based on CloudStack. While the public cloud and private cloud were successfully designed and realized, virtualization technology was performed to combine them as hybrid cloud. After that, the inner-enterprise users could share the data resources with a high-efficiency and people on the outside could check the resources they were permitted as well.

Process of setting up the cloud computing platform by CloudStack

Introduction to CloudStack. CloudStack is an open source cloud platform developed by Citrix, it obeys the Apache2.0 agreement and takes Java as its language. It can set up public cloud, private cloud and hybrid cloud by forming a resource pool with all computing resources. Users can deploy their own cloud condition because the friendly Web interface and abundant API interface can easily satisfy both consumers' and developers' different requirements. The structure of CloudStack is shown in Fig. 1.

Deploying CloudStack. This paper deployed CloudStack with console. Fig. 2 shows the deployment process consists of preparatory work, user interface design and configuration.

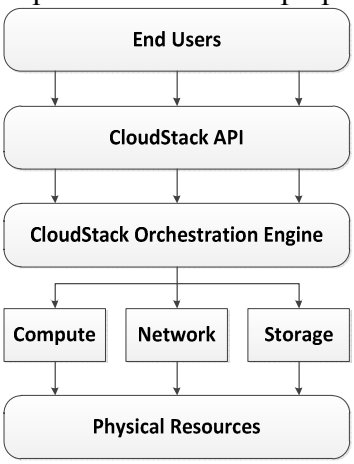

Fig.1 Structure of CloudStack

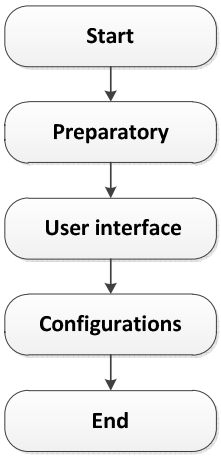

Fig.2 Procedure of Deploying

Preparatory work before configuration. The preparatory work included configuring the installation source, installing the Management Server, installing and configuring the virtualized Host mainframe of KVM.

Configuring the installation source means searching and downloading the installation package on the Internet. Generally, we download the CloudStack from its official website. The command is $ sudo vim /etc/apt/sources.list.d/cloudstack.list deb (http://cloudstack.apt-get.eu/ubuntu precise 4.0), in addition, the official certificate of the source is needed as well. If the installation of the system needs to update, just operate the command $ sudo apt-get updata.

During the installation of the Management Server, the first step needed to do is configuring the operating system's environment. While the hostname is obtained, we should add the record described as 10.6.203.10 cloudstack-server-1, which is used to map the server. Then the time server "openntpd" should be installed. Only by accomplishing above three steps , the CloudStack Management Server and vhd-util can be downloaded and installed. The command is $sudo apt-get install cloud-client. In order to acquire higher authority, the user must be added into the group sudo. Finally, the user group's password switch should be wiped off so that the users don't have to enter the password for every time. In the CloudStack, MySQL is usually chosen for storing and controlling data resources. MySQL can be installed with the command $ sudo apt-get install mysql-server and then configurate innodb_rollback_on_timeout as 1, innodb_lock_wait_timeout as 600, max_connections as 350, log-bin as myql-bin and binlog-format as 'Row'. Next, restart and initialize MySQL. Besides, NFS shared service is normally used for CloudStack's sharing data resources.

User interface. There is already a friendly interface in CloudStack so that once the configurations were accomplished, the platform of cloud computing was set up.

Configurations. This section discusses the most important part in the process of setting up the cloud computing platform. It includes configuration of the Management Server, installation of the Instance, establishment and customization of the Template and creation of the VM Instance.

Fig. 3 shows structure of the Mangement Server. Developers can modify and set up the Management Server via the Infrastructure interface, the steps are shown as follows: firstly, we need to make sure the value of Hypervisor as KVM; secondly, config Phycial Network by creating the

name of network and selecting the type of the network; thirdly, in order to control the interior communication of the CloudStack, the related network settings of Pod must be deployed; next, we should configurate Guest Traffic and Storage Traffic of the storage system so that we can distribute the IP address dynamically by Instance; At last, deploy the Host, the host machine of virtual machine, which is also called the Agent mainframe.

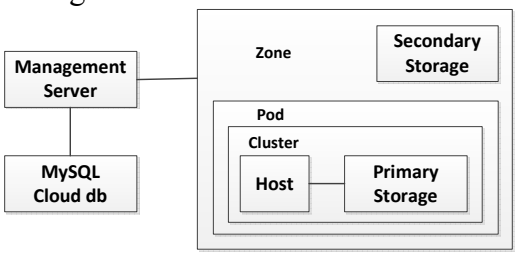

Fig.3 Structure of Management Server

Optimal settings. Normally, there is a guard time for Instances already deleted in CloudStack, however, it is really a long time lasting for 24 hours so that sometimes the system resources are quite insufficient. To cut down this duration, we should search for expunge and modify the parameter "expunge. interval" to a smaller value (such as 300s), and then restart Management Server.

Hybrid cloud based on virtualization technology

Virtualization ideas already exist, the IBM in the 1960s, firstly proposed and implemented that a single physical machine ran a number of different operating system instances, it subverted the traditional computing model which one computer only run one operating system instance. Multiple operating systems run on a single physical machine, sharing the physical machine resources (CPU resources, memory resources, network resources, storage resources, etc.). With the rapid development of computer hardware resources, many existing computer software has not fully utilize the hardware resources, so there are a lot of waste of resources.

Currently, the appearance of virtualization technology improve the utilization rate of hardware resources of the physical machine or server, and take full advantage of parallelism and high performance of hardware, besides, the administrator can eliminate the time and energy to manage a large number of physical machines.

These features of virtualization technology makes itself become one of the most valuable software technology among the whole computer technology, which plays a vital role in the cloud computing technology.

Resource classification. To build a hybrid cloud, you need to classify shared resources by different level, this paper proposes a method to classify. Arrange numbers to share resources in accordance with level of confidentiality, for example, the code of the most important resources within the enterprise is 1, followed by 2, and so on. As a result, the resources can be roughly divided into three parts: the private resources, public resources and ordinary resources. Private resources are the most important kinds of resources related to the survival and development of enterprises, it must not leak. Public resources must be known to the masses, such as product presentations, product categories, leadership team, etc. Common resources are not obvious limits, they can be available as private or public resources, and can be interchangeable.

Structure of Hybrid cloud based virtualization technology. As Shown in Fig.4, the main service consists of the virtual machine and authentication, using the above method to build a private cloud platform via the virtual machine, storing the private resources of corporation or institutions; While public cloud can be connected together by networks to form a large cloud platform, outsiders can access resources within the authority easily and efficiently.

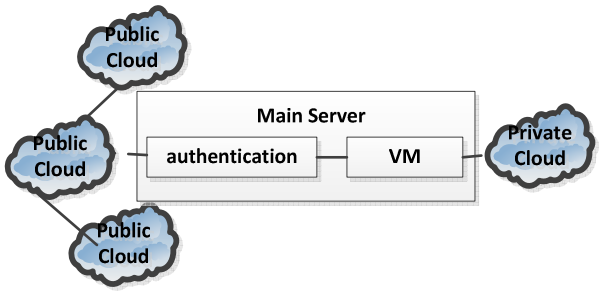

Fig.4 Structure of Hybrid Cloud

Summary

This paper proposes a design and implementation method of hybrid cloud computing platform based on CloudStack, in order to reduce complexity when using OpenStack as a development tool. On the basis of building methods of private cloud platform, introduce the virtualization technology twice, and create a mechanism for running a private cloud in a virtual machine environment. Besides, establish an authentication module, which isolate the private and public clouds to improve the security; And for managing easily, classify shared resources into three categories, which are private, public and general resources.

A Particle Swarm Optimization Algorithm Based on Simulated Annealing

Yan Zichao[a], Luo Yangshen[b]

School of Jinan University, Guangzhou 510632, China;

[a]yzcjnu@163.com, [b]lysjnu@126.com,

Keywords: Simulated Annealing, mutation, Particle swarm optimization

Abstract. The passage aims at solving the problems resulted from the optimized process of Particle Swarm Optimization (PSO), which might reduce the population diversity, cause the algorithm to convergence too early, etc. A whole new mutable simulated annealing particle swarm optimization is proposed based on the combine of the simulated annealing mechanism and mutation. This new algorithm substitutes the Metropolis criterion in the simulated annealing mechanism for mutagenic factors in the process of mutation, which both ensures the diversity of the particle swarm, and ameliorates the quality of the swarm, so that this algorithm would convergence to the global optimum. According to the result of simulated analysis, this hybrid algorithm maintains the simplicity of the particle swarm optimization, improves its capability of global optimization, and finally accelerates the convergence and enhances the precision of this algorithm.

Introduction

Particle Swarm Optimization,(PSO) is originally attributed to Kennedy, and Eberhart in 1995. This computational method simulates the predation process of the animal colonies such as bids and fishes, which is able to approach the global optimized result in continuous space. The substantive idea of this algorithm is simple, but it is easy to be ameliorated. More importantly, this algorithm has a strong convergence and high quality of optimization, which, therefore, is applied in a lot of fields such as industrial control, electric system, structural design, task scheduling and so on.

The basic algorithm of PSO can remarkably solve most of the optimization problems. However, when getting down to solve some of the problems.Facing these problems, many scholars put forward some outstanding solutions. Some other scholars proposed Unified PSO (UPSO) [3]. UPSO builds the neighbors of the particles, which can improve the topological structure of the particle swarm and prevent the algorithm from working out the local optimum. What's more, the combination between PSO and some other methods of intelligent optimization can lead to a perfect optimum and Simulate Annealing PSO (SAPSO) [4] is a typical case. In addition, Andrews came up with a new improved algorithm in 2006, Mutate PSO (SAPSO), which can increase the diversity of the particle swarm. The key is the fact that it is easy to manipulate the arguments of Mutate PSO method so that the quality and efficiency of the solution is improved.

The problem is, MPSO would cause two great defects in the process of mutation operation. The first flaw is that the capability of mutation will be weakened through the iterations continue, which will lead to the decrease of the swarm's diversity, while the second flaw would import numerous inferior solutions, which may stop the algorithm approaching the global optimized solution. To solve the problems and imperfections above, this article introduces Metropolis criterion in the simulated annealing mechanism and substitute it for the mutagenic factors in the process of mutation, and finally proposes an algorithm called Anneal Mutate Particle Swarm Optimization (AMPSO). Through the result of simulated analysis of Benchmark, it is shown that AMPSO maintains the simplicity of the particle swarm optimization, and lead the convergence to the global optimum.

1. A brief introduction of PSO

PSO simulates the searching process of extremum value by the particle swarm with the size of N in D-dimension space. The transmission dynamics models of the mutable particle is listed as follows:

$$\begin{aligned} v_i^{t+1} &= \omega \cdot v_i^t + c_1 \cdot \xi \cdot (p_i^t - x_i^t) + c_2 \cdot \eta \cdot (p_g^t - x_i^t) \\ x_i^{t+1} &= x_i^t + v_i^{t+1} \end{aligned} \quad (1)$$

In the formula, $x_i^k (i = 1 \cdots N)$ is the position of the i th particle at the t th time. $\boldsymbol{x_i^t} = (x_{i1}^t, x_{i2}^t, \cdots, x_{iD}^t)$ means the particle swarm is in a D-dimension space. $\boldsymbol{v_i^t} = (v_{i1}^t, v_{i2}^t, \cdots, v_{iD}^t)$ is the velocity of the i th particle at the t th time. $\boldsymbol{p_i^t} = (p_{i1}^t, p_{i2}^t, \cdots p_{iD}^t)$ is the particle's optimum location during the time period of $[1, t]$. ω, c_1, c_2 is inertia factor, self-directed learning factor and social learning factor. $\xi, \eta \in [0,1]$ is two pseudo-random numbers. PSO gains a good capability of optimization in continuous space, the schematic diagram of the particles' movement is listed as Figure 1.

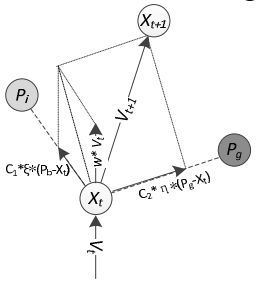

Figure 1. Schematic diagram of PSO

2. Traditional mutation process

The basic PSO has a problem of untimely convergence and working out the local optimum instead of global optimum. Andrews came up with a new improved algorithm in 2006, Mutate PSO (SAPSO) [4], which can increase the diversity of the particle swarm so as to prevent the untimely convergence. The mutation process destabilizes the particle's position through the variation function, and then restrains particle's mutation using particle's mutation probability and mutation factor so that the result can converge to the global optimum. Compared with other relevant algorithm, the mutation process has some good features such as its simplicity with less algorithm complexity.

The particle's variation function is the core of the mutation process, which can generate the new particle position and increase the particles' diversity using randomized strategy. The variation function used in this passage [8] is a classic one. x_{id} is the value of the i th particle at the d th dimension of space. $mutate(x_{id})$ is corresponding value after the mutation while $Guassian(\sigma)$ is a random number which obeys Gaussian distribution with the standard deviation of σ. $mutate(x_{id}) = x_{id} + Guassian(\sigma) \times x_{id} \quad (d = 1 \cdots D)$

For further details, pm_i (mutation probably) is the probability of the mutation by the i th particle in the swarm, while each particle's probability to cause the mutation is relatively different because the mutation probability is closely related to the particle's subscript. It is easy to modify the mutation probability of the whole particles swarm through the adjustment the relevant arguments α and β. In this case, $PopSize$ is the population size of the particles swarm.

$$pm_i = \alpha + \beta \frac{exp\left[\frac{5(i-1)}{PopSize-1}\right] - 1}{exp(5) - 1} \quad (2)$$

3. The mutation process base on simulated annealing mechanism

The mutation process will cause some imperfection. Early in the algorithm lifecycle, it is likely to import numerous inferior solution and at the same time extend the convergence process. At the later period of the algorithm, the capability of mutation will be weakened through the iterations continue, which will lead to the decrease of the swarm's diversity and finally the algorithm will lead to the local optimum instead of the global one. To improve the circumstance, this passage import the simulated annealing mechanism.

The simulated annealing(SA) mechanism can simulate the annealing process in the thermodynamics and lead the mutation particle to the global optimum after the temperature parameter declines gradually. SA mechanism use the Metropolis criterion to judge if the particle should update its new position via the mutation, which means the probability for the particle to accept $mutate(x_i)$. This probability is called pa_i (accepted probably):

$$pa_i = \begin{cases} 1 & f\left[mutate(x_i)\right] \geq f(x_i) \\ exp\left(\dfrac{f\left[mutate(x_i)\right] - f(x_i)}{T_t}\right) & f\left[mutate(x_i)\right] < f(x_i) \end{cases}$$

(3)For further details, $f(x_i)$ is the i th particle's fitness, T_t means the temperature parameter at the t th time period. The algorithm of the mutation process base on simulated annealed mechanism is listed as follows:

Algorithm of mutation process base on SA

1) Initialize $PopSize$, number of iteration $maxgen$, initial temperature T_0 , etc
2) $while(t < maxgen)$
3) Update the particles' position based on Equation (1)
4) $If\,(mod\left[t, step\right] == 0)$
5) $while(i \leq PopSize)$
6) $If\,(rand_1 < pm_i)$
7) Generate particles $mutate(x_i)$ based on Equation (2)
8) Generate random number $rand_2$
9) $If\,(rand_2 < pa_i)$
10) Update x_i with $mutate(x_i)$
11) $End\ If\,, End\ If\,, i = i + 1$
12) $End\ while, T_t = T_{t+1}, t = t + 1$
13) $End\ while$

Different from the mutation factor of the mutation process, this mechanism will not restrain particles' mutation, so that the high value of the diversity can be garanteed. What's more, this mechanism will choose the appropriate particle base on their fitness to imp rove the swarm's quality and finally work out the global convergence.

4. Simulated analysis

In this passage, the classic function[11] Tablet，Quadric，Rosenbrock，Grewank, etc are used to test and analyse the performance and efficiency of this algorithm. In addition, the result is compared with the one from standard PSO, UPSO, SAPSO, MPSO and AMPSO. The whole testing process is executed by the computer base on Intel Core i3 3.00 GHz processor, 4GB memory, 1TB hard disk, with runtime environment of Matlab 2013a. The functions are listed in Table 1

Name	Function	Search Space	Best position
Tablet	$f(x)=10^6 x_1^2+\sum_{i=2}^{30} x_i^2$	(-100,100)	$(0,\cdots,0)$
Quadric	$f(x)=\sum_{i=1}^{30}\sum_{j=1}^{i} x_j^2$	(-100,100)	$(0,\cdots,0)$
Rosenbrock	$f(x)=\sum_{i=1}^{n-1}\left[100(x_{i+1}+x_i^2)+(1-x_i)^2\right]$	(-5,5)	$(1,\cdots,1)$
Grewank	$f(x)=10^6 x_1^2+\sum_{i=2}^{n} x_i^2$	(-300,300)	$(0,\cdots,0)$

Figure 2 to Figure5 describe the comparison of the converge process among these five algorithm tested by the four Benchmark functions independently in 20 times. It is shown that in the algorithm of PSO, the diversity of the particle swarm declines through the converge process, which has a serious prematurity phenomenon. The algorithm of UPSO and SAPSO improve the swarm's diversity in different ways, which can work out a better result. However, these two algorithms do a limited improvement to the result because they can not solve the problem of leading to the local optimum untimely. MPSO has a great performance and high speed convergence, but later in the lifecycle, its diversity begins to decline and cause its performance to decrease. Lastly, the algorithm of AMPSO maintains the diversity and quality of the swarm, improves its capability of global optimization finally accelerates the convergence and enhances the precision of this algorithm.

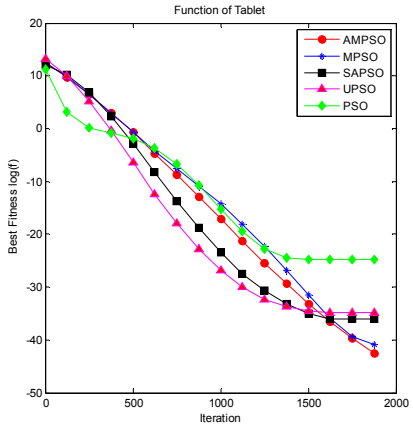

Figure 2

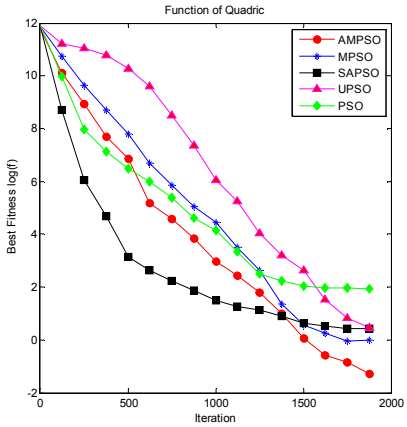

Figure 3

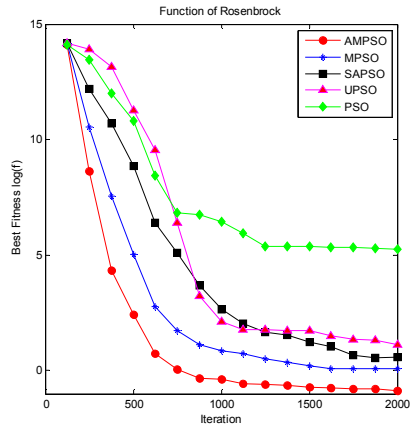

Figure 1

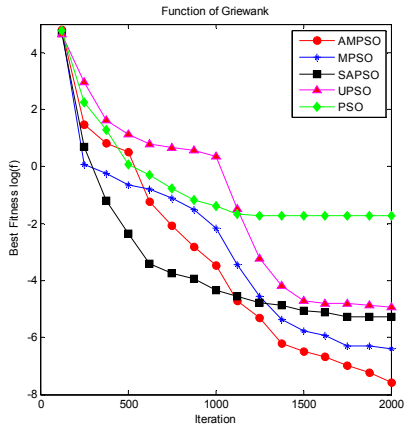

Figure 2

Conclusion

Particle Swarm Optimization(PSO), which might reduce the population diversity, cause the algorithm to convergence too early, etc. This new algorithm substitutes the Metropolis criterion in the simulated annealing mechanism for mutagenic factors in the process of mutation, which both ensures the diversity of the particle swarm, and ameliorates the quality of the swarm, so that this algorithm would convergence to the global optimum. According to the result of simulated analysis, this hybrid algorithm maintains the simplicity of the particle swarm optimization, improves its capability of global optimization and finally accelerates the convergence and enhances the precision of this algorithm.

There are two imperfections in the algorithm of MPSO, which is the decreasing diversity through the algorithm and the appearance of numerous inferior solutions. By introducing the mechanism of the simulated annealing, the ameliorated algorithm improves the diversity of the swarm so that it is not likely for the algorithm to work out the local optimum. By its Metropolis criterion, AMPSO can filter the inferior particles and finally improves the quality of the particles so that the improved optimization is on the way.

Keywords: Non-coal mine accident cause; Grey correlation analysis; Grey correlation degree; Grey correlation order; Mine accident risk.

Abstract: The Gray Relation Analysis is applied to the casualty analysis of non-coal mine accident in four certain years in China to export grey relational order to determine the main related factors in the non-coal mine accident, obtaining quantitative analysis results of the relationship between non-coal mine accident and multiple factors, introducing the concept of mine accident risk correlation degree.

Introduction

Non-mine mines mean the mine that mines metal ores, radioactive ores as well as building materials, refractory materials, petroleum chemical raw materials, auxiliary materials and other non-metal minerals [1]. Our country obtains a high incidence of non-coal mine production safety accident, for example, the mortality per million tons of ore is 30 times more than developed country in mining such as the United States. Non-coal mine accidents not only seriously threaten operation safety of miners and restrict the sustainable development of mine, but also bring enormous loss to national economy, so it has important practical significance to the occurrence of non-coal mine accident cause factor analysis.

Because the mine accident system is a multi-factor, multi-level and multi-objective mutual connection and restriction giant system, and its operation process is a grey dynamic process composed of many perplexing relationship, therefore, it is quite reasonable to use the grey system theory to analyze related factors of accident system.

The Summary of gray correlation analysis

The basic principle of grey correlation analysis. The basic idea of grey relational analysis is to determine whether they contact closely based on the similarity of sequence curve geometry. The closer the curve is, the greater the correlation degree between corresponding sequences is, whereas the smaller. That is to say, based on the degree of similarity or dissimilarity of development among various factors, it measures the correlation degree between factors. It doesn't make excessive demands on the number of the sample size, doesn't require the typical probability distribution, due to the small sample size makes little calculation, and will not appear that quantitative correlation results are inconsistent with the qualitative analysis of the situation, so than regression analysis, analysis of variance, principal component analysis, it is more practical and effective [2].

The procedure of grey correlation analysis. The grey correlation analysis is a quantitative analysis based on the qualitative analysis, an integral comparative analysis with the reference system and measure, can quantify and order factors through the analysis of the "incomplete information", "less", "not sure" system [3]. Its calculation steps are as follows [4]:

A. To determine the reference sequence (standard sequence) and comparative sequence.

B. The original data initialization. In practice, to solve the problem that the data dimension is not same as the absolute value, we need nondimensionalize and utilize the date to gain new comparative sequence. The paper takes the average method to implement transformation of data sequence, which is a list of data respectively divided by the average of every data to get a list of new series of average percentage. The dimensionless data sequence is [5]:

$$X_0(k)=\frac{Y_0(k)}{\frac{1}{n}\sum_{t=1}^{n}Y_0(t)}\quad X_i(k)=\frac{Y_i(k)}{\frac{1}{n}\sum_{t=1}^{n}Y_i(t)},i=1,2,\cdots,m;k=1,2,\cdots,n \tag{1}$$

In (1), Y_0 and Y_i are the original data.

C. The evaluation of sequence of difference.

$$\Delta_i(\mathrm{k})=\left|x_0(k)-x_i(k)\right|,\ \ \Delta_i(k)=\left(\Delta_i(1),\Delta_i(2),\cdots,\Delta_i(n)\right),i=1,2,\cdots,m \tag{2}$$

D. The evaluation of the polar difference $\mathrm{M}=\max_i \max_k \Delta_i(\mathrm{k}),\mathrm{m}=\min_i \min_k \Delta_i(\mathrm{k})$ (3)

E. The evaluation of the correlation coefficient.

$$\gamma_{0i}(k)=\frac{m+\varepsilon M}{\Delta_i(k)+\varepsilon M},k=1,2,\cdots,n;i=1,2,\cdots,m \tag{4}$$

ε -resolution ratio.

F. The evaluation of the correlation degree.

$$\gamma_{oi}=\frac{1}{n}\sum_{k=1}^{n}\gamma_{0i}(k),i=1,2,\cdots,m \tag{5}$$

The grey correlation analysis of accident cause in the non-coal mine

According to the above statement, combined with the accident classification statistics based on the accident cause of the national non-coal mine accidents in certain years(Table 1), the paper select the total number of deaths, the total number of accidents as a reference sequence, denoted by Y_0， Y_{00}.

The correlation degree for the total number of deaths and various factors.

A. To determine the comparative sequence. To select the following factors related to the mine accident as comparative sequences: Technology and design defects Y_1; Defective tools accessories of equipment and facilities Y_2; Missing or defective safety equipment Y_3; Adverse workplace environment Y_4; Ppe missing or defective Y_5; No safety procedures or inadequate Y_6; Violation of rules or labor discipline Y_7; Unreasonable labor organization Y_8; The lack of on-site inspection or command error Y_9; No enough training and lack of the safety operation knowledge Y_{10}; Others Y_{11}.

Table 1 The accident classification statistics based on the accident cause of the national non-coal mine accidents in certain years [6]

	2010	2011	2012	2013	Total

$$M=\max_i \max_k \Delta_i(k)=0.526,\ m=\min_i \min_k \Delta_i(k)=0.011$$

D.The evaluation of the correlation coefficient. Taking ε=0.5 based on the minimum information principle, by the table 2 and (4), we can calculate the correlation coefficient.

E. The evaluation of the correlation degree. By (5), we can calculate the gray correlation degree of the toll Y_0 and various factors, the results shown in Table 3.

Table 3 The gray correlation degree of the toll and various factors

i	1	2	3	4	5	6	7	8	9	10	11
γ_{oi}	0.759	0.775	0.728	0.772	0.520	0.727	0.789	0.755	0.548	0.762	0.583

The evaluation of the correlation degree of the total number of accidents Y_{00} and the number of various accidents. The results are shown in Table4.

Table 4 The correlation degree of the number of accidents and various factors

i	1	2	3	4	5	6	7	8	9	10	11
γ_{00i}	0.841	0.726	0.819	0.824	0.506	0.770	0.884	0.868	0.662	0.833	0.680

Analysis of the results

From the table 3, we can get the grey relational rank of the grey correlation degree of the death roll and various factors, shown: $\gamma_{07} > \gamma_{02} > \gamma_{04} > \gamma_{10} > \gamma_{08} > \gamma_{05} > \gamma_{06} > \gamma_{11} > \gamma_{09} > \gamma_{05}$. The above shows that the extent of the impact on the mine accident death toll of different factors is different, in which violation of rules or labor discipline X_7, defective tools accessories of equipment and facilities X_2, adverse workplace environment X_4, no enough training and lack of the safety operation knowledge X_{10} are respectively one of the greatest impact on mine accident death toll. It shows: the safety awareness of workers should be improved, while the safety training needs strengthening; the safety management system of mine should be perfect, while safety management efforts need to be increased; mine production condition is bad, so we need to improve working environment, which is important to reduce the loss of the accident.

From the table 4, we can get the grey relational rank of the grey correlation degree of the number of accidents and various factors, shown: $\gamma_{07} > \gamma_{08} > \gamma_{01} > \gamma_{10} > \gamma_{04} > \gamma_{03} > \gamma_{06} > \gamma_{11} > \gamma_{09} > \gamma_{05}$ .The above proves that the extent of the impact on the number of accidents of different factors is different,

in which violation of rules or labor discipline X_7, unreasonable labor organization X_8, Technology and design defects X_1, no enough training and lack of the safety operation knowledge X_{10} are more likely to cause accidents. Therefore, in addition to countermeasures mentioned in (1), improving labor organization in the mine production, adopting reasonable equipment, improving equipment man-machine matching degree, enhancing the adaptation of the human and machine all contribute to reducing accidents.

From (1) and (2), we can see that the rank of γ_{0i} is not always as same as the rank of γ_{00i}, which shows that the influence degree of various factors on the occurrence of accidents in mines is not consistent with the influence degree of various factors on the loss of mine accident. Therefore, we are to follow the relationship among risks, the probability of the accident, and the consequences of the accident to put forward the concept of the mine accident risk correlation degree named λ to measure the degree of influence of various factors on the mine, whose calculation formula is as follows:

$$\lambda_{0i}=\gamma_{0i}\times\gamma_{00i} \tag{6}$$

Through (6), we can calculate the accident risk, the results shown in Table 5.

Table 5 The accident risk of various factors

i	1	2	3	4	5	6	7	8	9	10	11
λ_{0i}	0.638	0.563	0.596	0.636	0.263	0.560	0.697	0.673	0.363	0.635	0.396

From the table 8, we can obtain that the accident risk of violation of rules or labor discipline X_7, unreasonable labor organization X_8, adverse workplace environment X_4, technology and design defects X_1 is relatively larger. So, the mine ought to increase the investment of safety education, mining equipment, and operating environment, and optimize the organizational structure of their labor; in addition, The State Administration of Work Safety is also supposed to increase the supervision of the four aspects mentioned previously, to strive to reduce accidents and the loss caused by incidents (the paper mainly aims to the accident death toll).

Conclusion

The paper adopts the grey relation analysis method to analyze various factors that may lead to mine accidents two aspects of γ_{oi} and γ_{o0i}. Because of the deference of γ_{oi} and γ_{o0i}, we put forward the concept of the mine accident risk to find out the accident cause and understand the impact degree of various factors on the accident system, which provides an important scientific basis for control accident factors, has a certain guiding significance and practical value on the safety planning and accident prevention in the future of mining enterprises and relevant government agencies.

Keywords: Single-Gaussian background modeling; moving objects detection; dynamic update rate

Abstract. Single Gaussian background modeling is often used in the static scene. In order to overcome the deficiency of the traditional single Gaussian background subtraction method, an improved adaptive background modeling algorithm was proposed. First, the number of each pixel in the image determined as foreground that were as the parameters of each pixel update rate were counted respectively. So the original fixed update rate was transformed into the dynamic update rate changing with the parameter. In this way, the phenomena of ghosting and shelling was suppressed effectively in the traditional single model of Gauss. Finally, foreground objects were obtained by using the method of shadow removal based on morphological reconstruction. The experimental results indicate that the algorithm can quickly and accurately establish and update the background model, and extract the moving object effectively. Compared with existing approaches, experimental results with different real scenes demonstrate the robustness of the proposed method.

Introduction

Moving object detection is very basic topics in the field of computer vision, which has important implications for the latter part of the target tracking and behavior analysis. Commonly used methods of moving target detection are frame difference, background subtraction and optical flow method. Frame difference method does not need the background modeling, just using the current and previous frame for subtraction to extract moving objects, so the calculation speed is very quick. The background difference method is a method used by the current frame and the background model to extract the moving object. Commonly Background modeling methods are average method background modeling, median method background modeling, single Gauss background modeling [1], mixed Gauss background modeling [2]. Optical flow method [3] is an important method for analyzing motion on images. From a single image, it can detect the independently moving targets, which can be used for camera motion environment, but it closes a relatively large amount of computation, and easily affected by the noise. Currently the most widely used target detection algorithm is based on a single Gaussian model. Due to the presence of smear and shelling phenomenon traditional single in Gaussian model, this paper presents an improved adaptive single Gaussian background modeling algorithm, which will effectively address these issues.

Single Gaussian Background Model

Due to external factors is very complex, Video image pixel values of each pixel in the change will be affected by external interference factors, and this approximate satisfy mathematical Gaussian distribution, so it is common to use single Gaussian model of image background to model. When a moving target gets through background, at that point pixels obvious change will happen, no longer meet the Gaussian distribution, this feature can be used to judge the pixel points for future.

Single Gaussian Model Building. In Ref. [4,5], first extract the top N frame image information from the video, and then calculate the average value of pixels as the mean value of each point: $\mu_0(x,y)$, Finally, calculate the variance of every frame of each point by the mean value, the mean of variance as the variance of each pixel, a single Gauss model initialization:

$$\mu_0(x,y) = \frac{1}{n}\sum_{i=0}^{n-1} f_i(x,y) \tag{1}$$

$$\delta_0^2 = \frac{1}{n}\sum_{i=0}^{n-1}[f_i(x,y) - \mu_0(x,y)]^2 \tag{2}$$

In this paper, this process is simplified by experiment here, and just take the first frame of the video to initialize a single Gaussian model, considering the value of each pixel as the mean of the point $\mu(x,y)$, and give a large variance $\delta(x,y)$, which is the coordinates of the pixel point x, y.

Single Gaussian Model Update. The traditional model update has two ways, one is global update on the pixel of background model, the other is selective updates on a model of the background pixels. Global update refers to the whole image pixels updated in accordance with the formula (3), among which α is the update rate, usually empiric constants. When the moving object enters the scene, occluded background pixels by the target will be changed, and global update according to the formula (3), then the pixel information of moving targets will be incorporated into the background, the updated background is no longer practical background. After moving target leave, the actual background re-emerge, then the actual background is sentenced to prospects, causing misjudgment, resulting in smearing.

$$\boldsymbol{B}_{t+1} = (1-\alpha)\boldsymbol{B}_t + \alpha \boldsymbol{I}_{t+1} \tag{3}$$

Among them, $\mathbf{I}_t$ is the pixel information of moment t, $\boldsymbol{B}_t$ is the background model of moment t, $\boldsymbol{B}_{t+1}$ is updated background model from moment t to $t+1$. From Equation (3) shows that, when the α becomes larger, indicate the current frame and into the background model information faster, all the tests in this article take = 0.1.

(a)the 119th frames original image (b)the 119th frame single channel real-time background(c)the two value goals the foreground image of the 119th frame

Fig. 1 The traditional single Gauss model tailing phenomenon

All experiments in this paper are based on VS2008 platform C language environment, the first and second experiment video sections are a section of 280 frames vehicle motion in the standard test video. In Figure 1, (a) is a video of the 119th frames of the original image, (b) is the 119th frame single channel real-time background image. From the background you can see a vague white car, it is because of the background of the global point of interest information before making updates to the melt in the background model, the update of the background global makes the top attractions information into the background model, while the white car's information can gradually disappear through a multi-frame, this will cause the car rear path detected as foreground, make the car after a long tail. (c) is the two value goals the foreground image of the 119th frame through the traditional single-Gaussian model algorithm processing, obviously, after the rear there is a long tail, which is usually called the trailing phenomenon.

In order to overcome the global updating algorithm tailing phenomenon, KOLLER et al. proposed a single Gauss model of selective updating method (6). The method first determine whether the current point belongs to the foreground or background, if it is the background, update the points according to the formula (4), (5), if it is the future, do not update background model, so the foreground information does not melt in the background model, and ultimately avoid the tailing phenomenon.

$$\mu_{t+1}(x,y) = (1-\alpha)\mu_t(x,y) + \alpha \boldsymbol{I}_{t+1}(x,y) \tag{4}$$

$$\delta_{t+1}^2(x,y) = (1-\alpha)\delta_t^2(x,y) + \alpha[\mathbf{I}_{t+1}(x,y) - \mu_t(x,y)]^2 \tag{5}$$

Although selective update method proposed here avoid the tailing phenomenon, but a new problem has emerged.

Due to which involved in updating is only the background, when the background object from static state to motion state, or foreground objects from a moving state to the stationary state into the

background, the background model cannot be updated in time, resulting in the background retains the target motion information before the status change, resulting in shelling phenomenon [7].

In Figure 2, (a) is a video of the 119th frames of the original image, (b) is the 119th frame single channel real-time background image. From the background you can see a vague white car, it's mainly because the car left from the first frame is not updated background model, which led to the road being detected as foreground, becoming a target movement. (c) is the two value goals the foreground image of the 119th frame through the improved single-Gaussian model algorithm processing by KOLLER et al. obviously, the improved algorithm can well eliminate tailing phenomenon, but it also caused a serious phenomenon of shelling: at first frame left, a white car din't disappeared in the image.

a)the 119th frames original image (b)the 119th frame single channel real-time background(c)the two value goals the foreground image of the 119th frame

Fig. 2 The improved single Gauss model tailing phenomenon

The improved adaptive single Gaussian background model

Based on the analysis of section 1.2, to solve above problems, a new kind of background model update strategy is proposed Based on the global update background model: establish a counter for each pixel C, which Used to statistics the discriminant for future point the number of pixels to be continuous, and set a threshold value C_T, when $C \geq C_T$, the Counter C reset, as shown in type (6).

$$C_{t+1}(x,y) = \begin{cases} C_t(x,y)+1, if \ \ I_{t+1}(x,y) - \mu_t(x,y) < \lambda \delta_t(x,y) \\ \quad then \text{ pridicted to be backgrounngd} \\ 0, if \ \ C_t(x,y) \geq C_T \end{cases} \tag{6}$$

The background model is carried out in accordance with the formula (3) global update. But the update rate αreplaced by sigmoid function as follows:

$$\alpha = 1/(1+e^{0.05(C_T - C)}), \alpha \in (0,1] \tag{7}$$

For the traditional single Gaussian model background modeling, whether it is a global update model or selective update model. Their update rate are empirical constant, cannot reflect the change of background model well. In this paper, we use sigmoid function here to show how fast update rate change, at beginning, the value of the counter is 0, αis approximately equal to 0, shows that started slow outlook information into the background model, is approximately equal to 0, to avoid the trailing, When the counter C increases, Illustration background targets from static to movement into outlook or outlook goals from motion to rest and integrated into the background is more likely, so the value of αincreases, Indicates that the faster the rate of foreground points into background model, when $C = C_T$, $\alpha = 1$, Shows prospects point completely melt into background model, So we can successfully avoid hulling phenomenon.

Figure 3 Background updating experimental result.by using the method

The figure 3 (a-f), reflect, the original image in real time of the video, 87, 95, 32, 103, 111, 119 frames, the same as the (g-l), respectively, video, 87, 95, 32, 103, 111, 119 frames, the experimental results after dealing with the background model update algorithm, It can be seen from the figure 3 (l), The car does not exist the tail phenomenon in figure 1 (c) or the hulling phenomenon in figure 2 (c), illustrate the improvement of the proposed algorithm successfully avoid the trailing phenomenon of traditional single Gaussian model, And the selective update hulling phenomenon better inhibition at the same time.

At the same time, figure 3 experimental reflects the update algorithm in this paper relationship between the inhibition effect of size and hulling rate phenomenon. This article take the threshold $C_T = 200$, Such as type (7), Sigmoid function is monotone increasing function, when $C = 100$, $\alpha \approx 6.69 e^{-3}$, it explain that from 1 to 100 frames in this paper, the background model update rate is very small, the cumulative learning outlook pixel information is almost zero. In figure 3 (g), (h), (I) we can see, 1st frame on the left side of the white car left "shell" outline is almost the same, when C =150, C =180, C =200, the Update rates were $\alpha \approx 7.6 e^{-2}$, $\alpha \approx 0.27$, $\alpha = 1$, increased by nearly, Describes frame from 100 to 200 between the cumulative learning points the prospect of pixel information at a faster speed rate into the background model, In figure 3 (j), (k), (I) we can see, the 1st frame on the left side of the white car left "shell" outline gradually disappear.

Conclusion

In view of the traditional single gaussian model in the fixed update rate, this article Put forward a kind of based on improved adaptive moving target detection algorithm of single gaussian background model,which successfully solve the traditional single gaussian model of the tail, shells, and other issues.The experiment proved that, the single gaussian model based on adaptive moving target detection algorithm in indoor environment and the background is relatively stable in the outdoor environment are effectively improve the performance of the foreground object and more adaptability.

Keywords: OSHMS, Fuzzy Theory, AHP, performance evaluation

Abstract. Hierarchy evaluation system has been established through a phased analysis of functional properties of OSHMS system, based on four aspects: the file system specification, and the actual business integration, system scheme enforceable, the continuous improvement of the development. Quantitative performance evaluation results has been obtained by building Occupational Safety and Health Management System performance evaluation model through fuzzy theory. According to the rated existing occupation safety and health management system problems, suggestions for improvement are given.

Introduction

Occupation safety and health management system embodies the idea of system security in theory of modern safety science, which is an important means to organize and improve the internal management, reduce business risk and avoid losses, reflecting the fundamental purpose of the protection of human rights. Based on fuzzy theory, starting from the system files and operating conditions, analyzing in functional properties of the system through a phased, establishing hierarchy evaluation system, building occupational safety and health management system performance evaluation model with fuzzy theory, quantitative performance evaluation results was obtained, based on which guiding suggest improvements was given.

Performance evaluation index system and weight determination

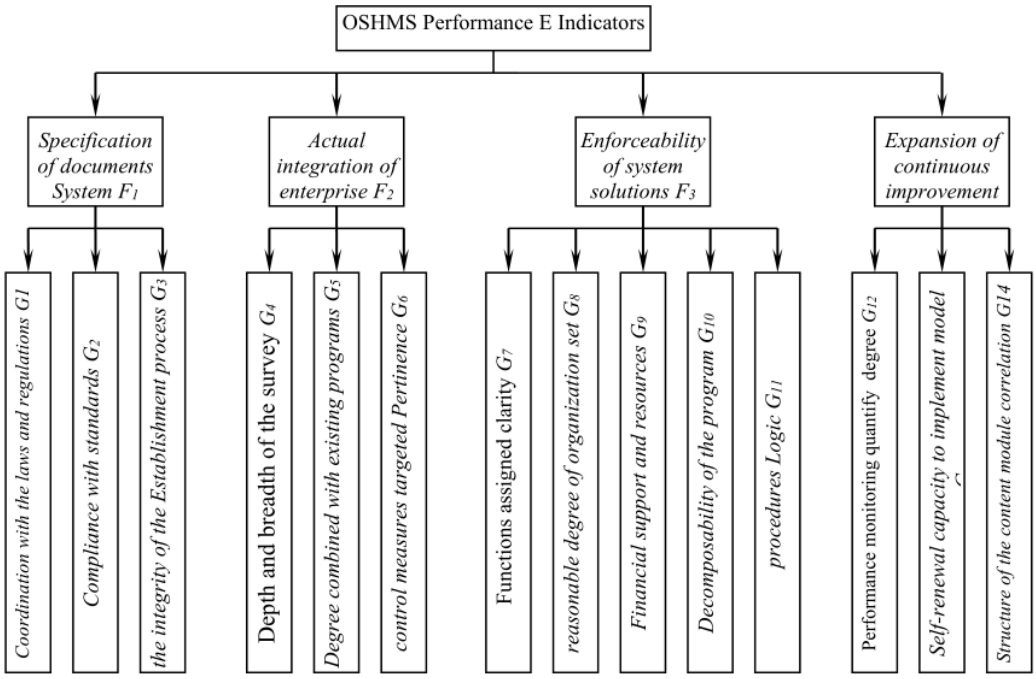

Figure 1 OSHMS performance evaluation index system

Performance evaluation index system determination. Occupational Safety and Health Management System (OSHMS) is a series of interrelated or interacting elements formulated for the establishment of occupational health and safety policy and objectives and the achievement of these objectives. Based on occupational safety and health management system functionality requirements, criteria layer for performance evaluation index system is established, including: (1) the file system specification, (2) and the actual business integration, (3) system scheme enforceable, (4) the continuous improvement of the development.

According to the established Occupational Safety and Health Management System performance criteria above, combined with the content they need to reflect, multi-factor and multi-level performance evaluation index system established is shown in Figure 1.

AHP to determine the weight of each index. For index 1, establish the discriminant matrix E-F for index 1; for index 2, establish the discriminant matrix F1-G, F2-G, F3-G, F4-G for index 2, among which the discriminant matrix scaling criterion uses the rule 1~9 scale method [3].

$$\text{E-F}=\begin{bmatrix}1 & 1/5 & 1/7 & 1/3\\ 5 & 1 & 1/3 & 3\\ 7 & 3 & 1 & 5\\ 3 & 1/3 & 1/5 & 1\end{bmatrix};\ \text{F1-G}=\begin{bmatrix}1 & 1/5 & 1/3\\ 5 & 1 & 3\\ 3 & 1/3 & 1\end{bmatrix};\ \text{F2-G}=\begin{bmatrix}1 & 2 & 1/3\\ 1/2 & 1 & 1/4\\ 3 & 4 & 1\end{bmatrix};$$

$$\text{F3-G}=\begin{bmatrix}1 & 5 & 7 & 1/3 & 3\\ 1/5 & 1 & 3 & 1/7 & 1/3\\ 1/7 & 1/3 & 1 & 1/9 & 1/5\\ 3 & 7 & 9 & 1 & 5\\ 1/3 & 3 & 5 & 1/5 & 1\end{bmatrix};\ \text{F4-G}=\begin{bmatrix}1 & 1/5 & 1/3\\ 5 & 1 & 3\\ 3 & 1/3 & 1\end{bmatrix}$$

The key to calculate the index weight with AHP [4] is to get the maximum eigenvalue and eigenvector of the matrix. The geometric mean method is used here, as well as Delphi7.0 programming processing judgment matrix, and the random consistency ratio is obtained: CRF-E=0.04447, CRF1-G=0.03703, CRF2-G=0.01759, CRF3-G=0.05423, CRF4-G=0.03703. Conformance testing are in line with requirements, and the weights calculated results is shown in Table 1.

Table. 1 OSHMS Performance evaluation index system weights Summary

class 1 index F	class 1 index weight W	class 2 index G	class 2 index weight W	class 1 index F	class 1s index weight W	class 2 index G	class 2 index weight W
F1	0.05502	G1	0.1047	F3	0.5638	G7	0.2638
		G2	0.6370			G8	0.0636
						G9	0.0329
		G3	0.2583			G10	0.5100
						G11	0.1296
F2	0.2634	G4	0.2385	F4	0.1178	G12	0.1047
		G5	0.1365			G13	0.6370
		G6	0.6250			G14	0.2583

Establishment of OSHMS performance evaluation model

Usually fuzzy comprehensive evaluation model has 3 basic elements: factor set, evaluation set and weight set, and the mathematical models are divided into single level model and multilevel model. The object will be assessed for two level model. The main steps are as follows:

Establish performance evaluation model of factors set. The factor set is a collection of the composition of elements influencing evaluation factors to assess the system. According to the evaluation index system established in 1.1, class 1 or 2 indexes corresponding to class 1 or 2 indexes influence factors in the performance evaluation model. A mathematical formula expressed as:

$$F=\{F1, F2, F3, F4\};\ F1=\{G1, G2, G3\};\ F2=\{G4, G5, G6\};$$
$$F3=\{G7, G8, G9, G10, G11\};\ F4=\{G12, G13, G14\};$$

Establish performance evaluation model. According to the calculation results of 1.2, OSHMS performance evaluation model weight set can be directly obtained: Class 1 weight set:W=[0.05502, 0.2634, 0.5638, 0.1178];

Class 2 weight set: w1=[0.1047, 0.6370, 0.2583]; w2=[0.2385, 0.1365, 0.6250];

w3=[0.2638, 0.0636, 0.0329, 0.5100, 0.1296]; w4=[0.1047, 0.6370, 0.2583];

Establish the evaluation set to model evaluate the performance. The purpose of fuzzy comprehensive evaluation is to obtain an optimal evaluation results from the evaluation set through taking into account all the factors judged. According to the characteristic of the evaluation object, OSHMS performance will be divided into five class. Objective evaluation criteria and evaluation criteria for each secondary factors are shown in Table 2 and Table 3.

Table. 2 OSHMS performance Objective evaluation criteria

The target value (100 full marks)	≥90	90-80	80-70	70-60	≤60
Objective evaluation grade	Level Ⅰ	Level Ⅱ	Level Ⅲ	Level Ⅳ	Level Ⅴ

Table. 3 Evaluation criteria for each secondary factors

The target value (%)	≥90	90-80	80-70	70-60	≤60
Fuzzy evaluation	Good	Well	General	Poor	Bad

Objective evaluation set: V={Level Ⅰ, Level Ⅱ, Level Ⅲ, Level Ⅳ, Level Ⅴ};

Secondary factors evaluation subset: v={Good, Well, General, Poor, Bad}.

Establish Performance level of fuzzy evaluation model. According to the evaluation criteria in Table 3, through questionnaire to the expert, calculate the frequency of appearance r that the secondary factors Gi (i = 1, 2, ..., n) relative to reviews vj (j = 1,2, ..., 5). Summarize and get four secondary factors set expert evaluation matrix Rm(m=1,2,3,4).

$$R_m = \frac{1}{N}\begin{bmatrix} r_{11} & r_{12} & r_{13} & r_{14} & r_{15} \\ r_{21} & r_{22} & r_{23} & r_{24} & r_{25} \\ r_{31} & r_{32} & r_{33} & r_{34} & r_{35} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ r_{n1} & r_{n2} & r_{n3} & r_{n4} & r_{n5} \end{bmatrix} \tag{1}$$

Here: rij: the frequency of the various experts evaluating on the i-th factors, whose results to the frequence that j-th comment that appears; N: total number of experts; n: number of secondary fuzzy actors set containing, here n = 14.

On the basis of fuzzy theory, secondary factor evaluation results:

$$S_{22} = \left[w_1 \bullet R_1 \quad w_2 \bullet R_2 \quad w_3 \bullet R_3 \quad w_4 \bullet R_4 \right]^{\mathrm{T}} \tag{2}$$

Goals (four first factors) Score: $S' = S_{22} \bullet D$ (3)

According to the evaluation criteria in Table 2, construct piecewise interpolation function, calculated: D=[95, 85, 75, 65, 25]T.

first factors evaluation results: $S_{11} = W \bullet S_{22}$ (4)

OSHMS Performance Overall score: $S = S_{11} \bullet D$ (5)

According to Table 2, evaluated OSHMS performance level can be derived and improved measures need to take.

OSHMS performance evaluation models Applications

Whether this method is operable or practical is verified to the object in an enterprise the new building Occupation safety and health management system. By Organizing 10 expert evaluating the OSHMS performance of each factor based on method in Table 3, build evaluation matrix as follows:

$$R_1=\begin{bmatrix}0.7 & 0.1 & 0.2 & 0 & 0\\ 0.5 & 0.2 & 0.1 & 0.2 & 0\\ 0.4 & 0.3 & 0.1 & 0.1 & 0.1\end{bmatrix};R_2=\begin{bmatrix}0.3 & 0.1 & 0.4 & 0 & 0.2\\ 0.2 & 0.1 & 0.3 & 0.3 & 0.1\\ 0.4 & 0.2 & 0 & 0.3 & 0.1\end{bmatrix};R_3=\begin{bmatrix}0.6 & 0.1 & 0.2 & 0.1 & 0\\ 0.2 & 0.4 & 0.1 & 0.1 & 0.2\\ 0.5 & 0.2 & 0.1 & 0.2 & 0\\ 0.4 & 0.3 & 0.2 & 0 & 0.1\\ 0.3 & 0.3 & 0.1 & 0.2 & 0.1\end{bmatrix};$$

$$R_4=\begin{bmatrix}0.2 & 0.1 & 0.3 & 0.2 & 0.2\\ 0.3 & 0.1 & 0.1 & 0.2 & 0.3\\ 0.4 & 0.2 & 0.2 & 0.1 & 0.1\end{bmatrix};$$

Substitute the matrix into the formula (2-5) and calculate, get level 1and 2 fuzzy subset:

$$S_{11}=\begin{bmatrix}0.39890 & 0.21058 & 0.15928 & 0.12590 & 0.10530\end{bmatrix}$$

$$S_{22}=\begin{bmatrix}0.49511 & 0.21536 & 0.11047 & 0.15323 & 0.02583\\ 0.34885 & 0.1625 & 0.13635 & 0.22845 & 0.12385\\ 0.43033 & 0.25028 & 0.17737 & 0.06524 & 0.07668\\ 0.31536 & 0.12583 & 0.14677 & 0.17417 & 0.23787\end{bmatrix}$$

Level 1 index score and OSHMS performance scores were:

$$S^{'}=\begin{bmatrix}84.23 & 75.13 & 81.62 & 68.93\end{bmatrix}^{T};\ \mathrm{S}=78.56$$

According to Table 2, OSHMS performance looks general, and there is still much room for improvement, combined with an index score, we can get following conclusions:(1) The Occupational Safety and Health Management System is above the middle level, and the overall performance is balanced; (2) Lackness of the enterprise system's effectiveness and ability to update is slightly larger. In the process of the system improvement,when overhauling you need to emphasis on two reform efforts item:"the expansion of continuous improvement" and "practical integration with enterprise "at the same.

Conclusion

Features and application value of the occupational safety and health management system performance evaluation method are as the following : (1) According to functional requirements of OSHMS in the life cycle , on this basis of deep analysis of the construction of OSHMS various problems that may arise, OSHMS performance evaluation index system was reflected to ensure that the entire index system is scientific and comprehensive;(2) By the method combining the analytic hierarchy process with fuzzy theory, the multi-level and multifactorial OSHMS performance problems have been effectively solved, and objective quantitative assessment performance results of OSHMS have been get; (3) According to the results of the OSHMS performance evaluation, targeted improvement strategies have been proposed for OSHMS with relatively poor level of performance.

Keywords: Multivariate Data Visualization, Clutter reduction, Parallel Sets, measurement ratio, corresponding degree for categorical measures

Abstract. Classic part-labeled data visualization method Parallel Sets is applied to represent visualization of multivariate data with measures. Currently, in all walks of life emerge abundant small records and documents. Thus to sort the massive categorical measures of small value on the variable axis plays an important role in reducing clutters in the view. This paper is based on the Advanced Categories Layout basEd on Average heuRistic with Cardinality Reduction (ACLEARCR), and proposes an optimization sequence algorithm aiming at categorical measures of small value. The case study proves that the proposed method is effective.

Introduction

Multivariate data with measures of metric attributes [9] has been explored in depth in data mining (DM). The classical analysis method is so-called On-Line Analytical Processing (OLAP) technique. OLAP provides various visualization tools [1-6].

A traditional visualization method is Parallel Sets. There is not a strict process when using parallel sets for visualization. Through picking up interested variables and categorical measures and adding them into the panel, users may conduct visualization analysis. A small number of variables and categorical measures often result in layout confusion. Therefore when conducting visualization users should only choose interested variables and categorical measures and re-choose after analysis completion. Though Parallel Sets allow users to sort the variable axis and its categorical measures' sequence through drag and drop interaction, manual manipulation is quite complex and difficult to guarantee satisfying layout. Edges intersection quantity between two parallel variable axes is closely related to their corresponding nodes sequence [8]. If categorical measures of big value as well as small ones intersect, it may invisibly result in display confusion and ignorance on categorical measures of small values. Such condition can be avoided through sorting variables according to the categorical measures sequence. Sorting massive categorical measures of small values on the variable axis can effectively increase the readability.

Relate work

To solve the problem that categorical measures randomly sequenced by Parallel Sets may generate too many intersections, ref. [7] proposed Categories Arrangement based on MEdian heuristic (CAME). Ref. [8] further came up with Categories Layout basEd on Average heuRistic with Cardinality Reduction (CLEARCR), which may automatically optimize the layout of categorical measures on each variable axes and effectively reduce the visual confusion. Ref. [9] computes measurement of each categorical measure of each axis and takes it as sorting reference (CLEARCR). Thus the view tends to place the categorical measures of big value on the front-end of each variable axis and small value ones on the back-end.

Algorithm

The sequence of categorical measures is a key factor leading to the displays confusion of parallel sets. In general, if categorical measures of small values have too decentralized configurations, it may invisibly lead to display confusion.

Multidimensional data is defined as follows [10]:

Assume $G(F)=\{F^1,F^2,\cdots,F^m\}$ is a given object set of k-dimension (k>0). Among, m i is the set base, namely the number of multidimensional objects. $F^i=F^i(f_1^i,f_2^i,\cdots,f_k^i)(f_j^i\in R,f_j^i\geq 0)$ represents a k-dimension object of the set. $f_1^i,f_2^i,\cdots,f_k^i$ indicates the k-dimension attribute value of each object. For multidimensional attribute data table $G(F)$, F^i represents a record and f_j^i is its corresponding value.

Measurement of categorical measures is defined as [59]:

In consideration of variable $V_l(1\leq l\leq k-1)$ from multivariable data set of measurement attribute, assume $\{v_1,v_2,\cdots,v_n\}$ is n categorical measures of V_l. Then in the entire data set the measurement of any categorical values $v_i(1\leq i\leq n)$ can be represented as $Q(v_i)=\sum_{j=1}^{m}q^j\big|_{V_l=v_i}$, namely $Q(v_i)$ is the sum of all v_i categorical values variable that V_l is assigned. $Q(v_i)$ is named as the measurement of $v_i(1\leq i\leq n)$.

According to the above definitions, the corresponding degree and metric ratio of categorical measures is given.

Definition 1:

To categorical measures $\{v_1,v_2,\cdots,v_n\}$ of variable $v_i(1\leq i\leq n)$ in multivariable data table of measurement attribute $G(F)$, in the entire data set the corresponding degree with the adjacent variable's categorical measures any categorical measures $v_i(1\leq i\leq n)$ can be expressed as $D(v_i)$.

Definition 2:

To categorical measures $\{v_1,v_2,\cdots,v_n\}$ of variable $v_i(1\leq i\leq n)$ in multivariable data table of measurement attribute $G(F)$, the metric ratio of any categorical measures $v_i(1\leq i\leq n)$ value among all categorical measures of the variables can be expressed as $R(v_i)$.

On the basis of corresponding degree and quantity ratio of categorical measure, we re-compute measurement for each categorical measure as reference. Based on the ACLEARCR algorithm, we propose an optimized sorting algorithm targeting on the categorical measures of small value.

Table 1 Algorithm flow

1. Compute measurement:

According to ref. [9], calculate measurement of categorical measures on each variable axis in the Parallel Sets view.

2. Node Cluster:

Cluster method consults CLEARCR algorithm. Cluster layer by layer in accordance with top to bottom sequence of view variable axes. Change the weigh of categorical measures on the basis of conditions to form new layer G', and conduct optimization according to the improved ACLEARCR algorithm.

3. Re-compute measurement of categorical measures layer by layer:

3.1 . For the categorical measure $\{v_1,v_2,\cdots,v_n\}$ of the first initial variable V_1 of G, compute corresponding degree $D(v_i)$ of each categorical measure v_i and its adjacent variable's categorical measures, and record the categorical measures that relate;

3.2. For the categorical measure $\{v_1, v_2, \cdots, v_n\}$ of the first initial variable V_1 of G', compute quantity ratio $R(v_i)$ of each categorical measure v_i among all categorical measures of the variables;

3.3. Conduct layer variable sorting according to $D(v_i)$ and $R(v_i)$, thus receiving categorical measures sequence $sequence_i$. Compared with adjacent variable's categorical measures sequence $sequence_i$ and $sequence_{i+1}$, adjust the sequence on the basis of corresponding degree of each categorical measure recorded in 3.1, sorting the categorical measures by the rules that small values gather in the middle while big ones locates on both sides. The rest may be deduced by analogy to the categorical measures of all variables.

4. **Examine measurements in reverse:**

From the bottom to the top, according to 3, examine the measurement calculation of each categorical measure.

5. **Computation ends:**

Re-conduct **3** and **4** until the initial-set termination iteration condition reaches.

6. **View representation:**

Replace the old sequence with new categorical measures sequence and visualize each variable view.

From the description of the algorithm, two aspects has been improved to ACLEARCR:

(1) Variable of corresponding degree with adjacent variables had been introduced. Variables of time-varying multivariate data set usually relate with each other closely, which reflects fully on the categorical measures of different variables. When correspondence among categorical measures is out of consideration, sequence may not got optimized thus hard to form views with less confusion. Adding corresponding degree among different variables' categorical measurements is a representation of closely related variables, which fits for human being's cognitive habit.

(2) Consider quantity ratio that value of categorical measures occupies in all categorical measure values. Different categorical measures of each variable usually differ greatly. Considering metric ratio and sorting by the rules of small in the middle while big on both ends may avoid cognitive burden brought by big and small ones take place in turn. Centralization of small categorical measures makes for entire view representation.

Implementation

Prototype system hires SWT widget of Eclipse; operating system is Windows 7; configurations Intel(R) Core(TM) i5, 8 GB, ,500 GB hardware. Sales data from supermarket are used to prove the efficiency of the improved algorithm. Under the circumstances that the sequence of the variable axes is fixed and categorical measures keep still, we use the improved algorithm to optimize the categorical measures ranking, and compare the receiving views with the ACLEARCR and random arranged view.

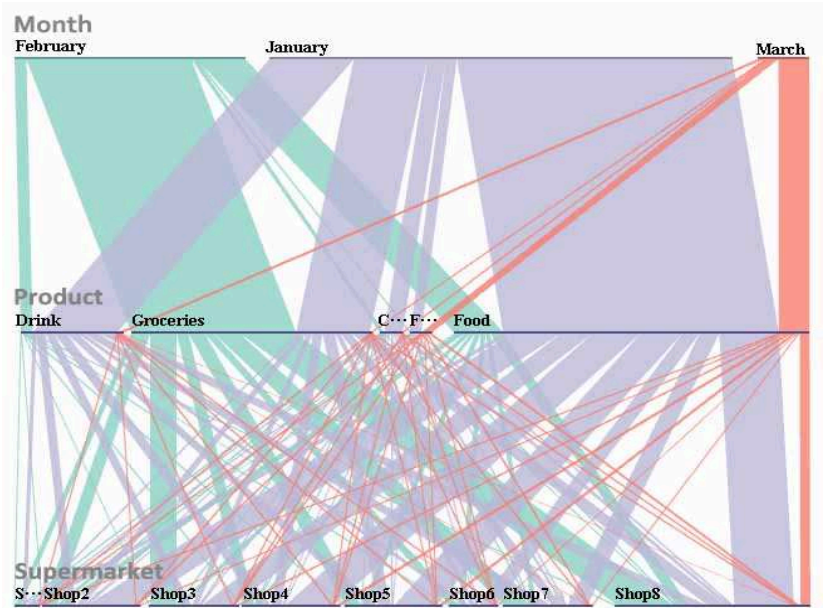

Fig.1 Random Arrangement

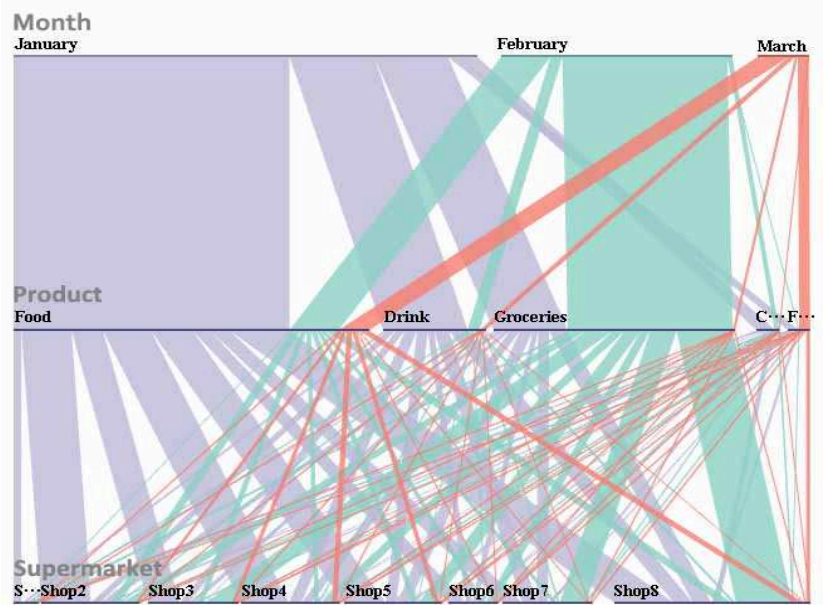

Fig.2 ACLEARCR

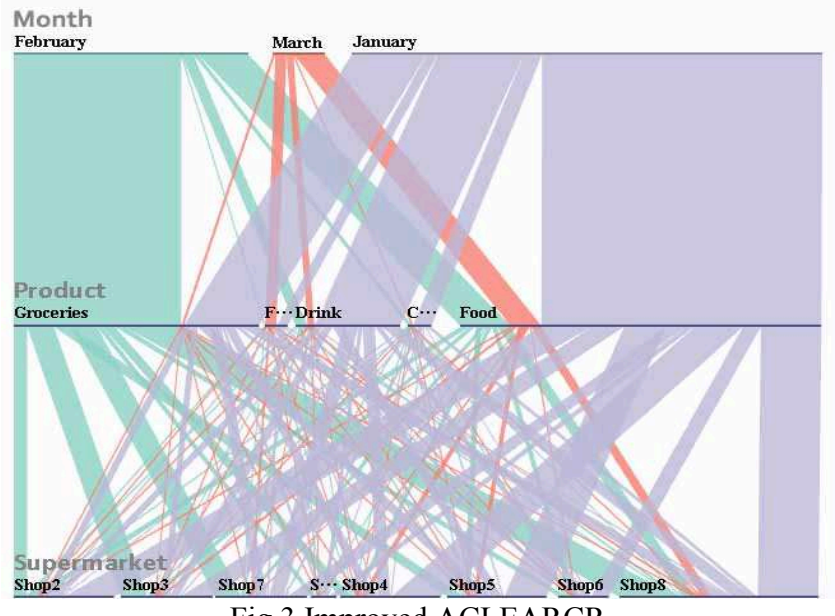

Fig.3 Improved ACLEARCR

From Fig .1, 2 and 3, it can be figured out that categorical measures ranks according to the rules that small ones gather in the middle while big ones on both sides. After optimized by ACLEARCR algorithm, re-ranking by the improved algorithm can make the view be prone to put the categorical measures of big value on both ends of each variable axis, and at meanwhile the small value ones and the ones of great correspondence with the others in the middle of the axes. From the transformation of the third variables it can be seen that ACLEARCR algorithm functions little when small value categorical measurement have many dividing values. However after considering measurement ratio and corresponding degree for categorical measures, the improved algorithm to a larger extent reduces the crossover occurrence of corresponding parallels, thus efficiently reducing visual confusion in the view.

Conclusion

This paper is based on the Advanced Categories Layout basEd on Average heuRistic with Cardinality Reduction (ACLEARCR), and proposes an optimization sequence algorithm aiming at categorical measures of small value. From the above analysis the improved ranking algorithm can obtain better visualization views compared with random arrangement and ACLEARCR algorithm. Therefore the advantage of the proposed ranking algorithm is proved.

Keywords: dynamic DEA; pure technical efficiency; pure scale efficiency; thermal infrared camouflage; evaluation

Abstract. For coping with modern thermal infrared reconnaissance, thermal infrared camouflage is becoming the hotspot of camouflage pattern research. Concerning the traditional methods on evaluating ground thermal infrared camouflage can't solve the "dynamic" problem and the pure technical as well as pure scale efficiency. This article established new models to figure it out. The new measure introduced time parameter to construct dynamic model, then it set up pure technical dynamic DEA model which supposed it had variable returns to scale. Through the relationship among technical, pure technical and pure scale DEA model, we can get the pure scale dynamic DEA model. Finally, an example was calculated which shows the application of the new models.

Introduction

The thermal infrared camouflage equipments can eliminate the targets' thermal infrared exposed character effectively in a tactical distance, reducing the probability of discovery, identification and enemy attack, which means a lot to the survivability of the military targets [1]. In such circumstance, a systemic and comprehensive method to evaluate the ground thermal infrared camouflage effect is of great significance [2]. Generally, a camouflage is usually selected based on a certain index, such as the investment of time, fund or camouflage effect. This kind of analysis is rough, qualitative and lack of practicality once involved multi index evaluation [3,4]. Currently, the methods for optimization primarily include AHP (analytic hierarchy process), FCE (fuzzy comprehensive evaluation method) and Grey-evaluation. However, it encounters problems determining the index weight such as strong subjectivity and obstacle of correlation constraint test [5]. DEA (Data Envelopment Analysis), a common and significant research method, is a relatively effective nonparametric method to evaluate DMU (Decision Making Unit). It can ignore the influence of evaluation index dimension, avoid the mutual restriction between the input and output index and effectively judge the relative effectiveness of DMUs [6,7]. The evaluation of ground thermal camouflage efficiency often comes to a time period, traditional DEA cannot deal with it suitably. Here, we extend it to dynamic one by introducing time parameters. Based on dynamic model, the paper changed constant returns to scale (CRS) to variable returns to scale (VRS). The new model which called pure technical dynamic DEA eliminated scale efficiency factor. Thus, technical efficiency was broken up to pure technical efficiency and pure scale efficiency, which provides more management information to supervisors.

Evaluation Index System of the Ground Thermal Infrared Camouflage

The camouflage effect need to be evaluated to examine whether it worked as expected. The thermal infrared camouflage effect evaluation index system of ground targets can be classified and analyzed from two aspects of input and output. The input can be sorted as: (1) Forces of operation (x_1): Corps of engineers camouflage unit involved in ground thermal infrared camouflage， takes single soldier as unit of measure for precision. (2) Time of operation (x_2): The time spend on carrying out the ground thermal infrared camouflage. Unit: hour. (3) Equipment of operation (x_3): The ground thermal infrared camouflage is complicated and has high demand on camouflage equipment. This

index refers to consumption of equipment. (4) Difference of average radiation temperature between camouflage target and background (x_4): The background of target is composed of many kinds of little background units with different thermal physical properties. The units with different thermal inertia formed a complicate thermal radiation distribution under sunshine [8]. Hence the difference of average radiation temperature between camouflage target and background is one of the indexes. (5) Difference of emissivity of two adjacent deformation spots (x_5): Object's radiation temperature is determined by surface emissivity. So we could use this index to quantify during the thermal infrared camouflage spots design [9].

The output can be described as: (1) Comprehensive similarity of thermal infrared image (y_1): the similar the thermal infrared recognition feature between target and background is, the better thermal infrared camouflage effects. The other way around works out as well [10]. (2) The similarity of thermal infrared radiation emissivity (y_2): if the thermal infrared radiation emissivity of target and typical objects in background is similar, then the bigger emissivity is the better camouflage effects [11].

Pure Technical Dynamic DEA

When evaluate the ground thermal camouflage, it often needs to evaluate the efficiency of a DMU in different time spot, which reflects the overall efficiency of the DMU in a period of time [12]. Introduce the time parameter into DEA model, set the number of DMU is n, in the t period the input and output indexes are respectively as follows:

$$X_j^t = \left(x_1^t, x_2^t, \cdots, x_n^t\right) = \begin{pmatrix} x_{11}^t \cdots x_{1j}^t \cdots x_{1n}^t \\ \cdots \quad \cdots \quad \cdots \quad \cdots \\ x_{i1}^t \cdots x_{ij}^t \cdots x_{in}^t \\ \cdots \quad \cdots \quad \cdots \quad \cdots \\ x_{m1}^t \cdots x_{mj}^t \cdots x_{mn}^t \end{pmatrix}_{m\times n} \quad Y_j^t = \left(y_1^t, y_2^t, \cdots, y_n^t\right) = \begin{pmatrix} y_{11}^t \cdots y_{1j}^t \cdots y_{1n}^t \\ \cdots \quad \cdots \quad \cdots \quad \cdots \\ y_{k1}^t \cdots y_{kj}^t \cdots y_{kn}^t \\ \cdots \quad \cdots \quad \cdots \quad \cdots \\ y_{s1}^t \cdots y_{sj}^t \cdots y_{sn}^t \end{pmatrix}_{s\times n}$$

On the basis of the introduction of time parameter, extend the DEA to a dynamic form. Dynamic C^2GS^2 model with non-Archimedean infinite small has been established, which considers the influence of scale efficiency. When we change the restrictions from CRS to VRS, pure technical dynamic DEA model can be built up as follows:

$$\begin{cases} \min\ [\sigma^t - \varepsilon(\hat{e}^T S^- + e^T S^+)] \\ \sum_{j=1}^{n} X_j^t \lambda_j^t + S^- = \sigma^t X_0^t \\ \sum_{j=1}^{n} Y_j^t \lambda_j^t - S^+ = Y_0^t \\ \sum_{j=1}^{n} \lambda_j^t = 1,\ S^- \geq 0\ ,\ S^+ \geq 0,\ \lambda_j^t \geq 0\ ,\ j = 1,2,\cdots,n \end{cases} \tag{1}$$

σ^t is the pure technical efficiency of DMU_0 in the *t* period. σ_j^t is the pure technical efficiency of DMU_j in the *t* period, j = 1,2,…,n. Thus the pure technical efficiency matrix of dynamic DEA can be given as σ_j^t.

$$\sigma_j^t = \left(\sigma_1^t, \sigma_2^t, \cdots \sigma_n^t\right) = \begin{pmatrix} \sigma_1^1 \cdots \sigma_j^1 \cdots \sigma_n^1 \\ \cdots \quad \cdots \quad \cdots \quad \cdots \\ \sigma_1^t \cdots \sigma_j^t \cdots \sigma_n^t \\ \cdots \quad \cdots \quad \cdots \quad \cdots \\ \sigma_1^T \cdots \sigma_j^T \cdots \sigma_n^T \end{pmatrix}_{T\times n} \tag{2}$$

Similarly, in order to evaluate pure technical efficiency of DEA of n DMUs in *T* period, set a new DEA unit[13]. The input vector is a unit vector which is 1×n and the output vector is the overall efficiency matrix of dynamic DEA (σ_j^t), to form a new DEA unit as below:

$$\begin{cases} \min\ [\beta-\varepsilon(\hat{e}^T S^- + e^T S^+)] = V_\sigma \\ \sum_{j=1}^{n} \lambda_j + S^- = \beta \\ \sum_{j=1}^{n} \sigma_j^t \lambda_j - S^+ = \sigma_0^t \\ \lambda_j \geq 0,\ j = 1,2,\cdots,n \\ S^- \geq 0,\ S^+ \geq 0 \end{cases} \tag{3}$$

Pure scale Efficiency Dynamic Evaluation

Infer from $\eta^* = \theta^* / \sigma^*$, η^* is the pure scale efficiency, θ^* is the overall technical efficiency and σ^* is the pure technical efficiency. Thus we can obtain the dynamic pure scale efficiency matrix as follows:

$$\eta_j^t = \left(\eta_1^t, \eta_2^t, \cdots \eta_n^t\right) = \begin{pmatrix} \eta_1^1 \cdots \eta_j^1 \cdots \eta_n^1 \\ \cdots \cdots \cdots \cdots \\ \eta_1^t \cdots \eta_j^t \cdots \eta_n^t \\ \cdots \cdots \cdots \cdots \\ \eta_1^T \cdots \eta_j^T \cdots \eta_n^T \end{pmatrix}_{T\times n} \tag{4}$$

$\eta_j^t = \theta_j^t / \sigma_j^t$， η_j^t is pure scale efficiency of DMUj in the t（$t = 1,2,\cdots T$）period, j = 1,2,⋯,n. Similarly, in order to evaluate pure scale efficiency of DEA of n DMUs in T period, set a new DEA unit. The input vector is a unit vector which is 1×n and the output vector is the overall efficiency matrix of dynamic DEA (η_j^t), pure scale dynamic DEA model can be given as:

$$\begin{cases} \min\ [\gamma-\varepsilon(\hat{e}^T S^- + e^T S^+)] = V_\eta \\ \sum_{j=1}^{n} \lambda_j + S^- = \gamma \\ \sum_{j=1}^{n} \eta_j^t \lambda_j - S^+ = \eta_0^t \\ \lambda_j \geq 0,\ j = 1,2,\cdots,n \\ S^- \geq 0,\ S^+ \geq 0 \end{cases} \tag{5}$$

Examples of Application

Take seven thermal infrared camouflage proposal of ground targets as an example to analyze its dynamic DEA efficiency in five periods (t=1,2,3,4,5). The dynamic evaluation data of DEA is shown in table 1.

The matrix of pure technical efficiency and pure scale efficiency can be given as below:

$$\sigma_j^t = \begin{pmatrix} 1 & 0.86 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0.84 & 0.82 & 1 & 1 & 1 & 1 \\ 1 & 0.86 & 0.83 & 1 & 1 & 1 & 1 \\ 1 & 0.87 & 0.84 & 1 & 1 & 1 & 1 \\ 1 & 0.80 & 0.85 & 1 & 0.99 & 1 & 1 \end{pmatrix} \qquad \eta_j^t = \begin{pmatrix} 1 & 1 & 0.36 & 0.94 & 0.64 & 0.78 & 1 \\ 0.96 & 1 & 0.66 & 0.97 & 0.86 & 0.89 & 1 \\ 0.89 & 1 & 0.36 & 0.91 & 0.53 & 0.66 & 1 \\ 1 & 1 & 0.62 & 0.87 & 0.83 & 0.47 & 1 \\ 1 & 1 & 0.8 & 1 & 0.81 & 0.57 & 1 \end{pmatrix}$$

Table 1 DEA dynamic evaluation data of ground thermal infrared camouflage

	DMU3	32	27	41	10	0.28	0.4	0.02	0.85	0.8
	DMU4	26	30	46	8	0.24	0.5	0.02	1	1
	DMU5	27	25	36	12	0.36	0.4	0.03	0.99	0.81
	DMU6	33	23	29	13	0.27	0.3	0.01	1	0.57
	DMU7	27	18	35	7	0.17	0.5	0.04	1	1

Table 2. Evaluation result of pure technical and pure scale dynamic DEA

DMUj	DMU_1	DMU_2	DMU_3	DMU_4	DMU_5	DMU_6	DMU_7
β_j	1	0.87	1	1	1	1	1
γ_j	1	1	0.80	1	0.86	0.89	1

Table 2 is the result of pure technical and pure scale dynamic DEA model. Except for DMU_2, the other six DMUs have high pure technical efficiency in the overall period. The dynamic DEA pure scale efficiency of DMU_1, DMU_2, DMU_4 and DMU_7 is 1, the others is less than 1.

Conclusion

Dynamic DEA model overcame the disadvantage of tradition DEA when the evaluation of ground thermal infrared camouflage had a time span. However, dynamic DEA had the restriction of CRS, which was influenced by scale efficiency. Alter the restriction of CRS to VRS, pure technical dynamic DEA was set up and the impact of scale factor could be avoided. Pure scale dynamic DEA was established through the relationship among overall efficiency, pure technical efficiency and pure scale efficiency. New models provided the managers more information. When the ground thermal infrared camouflage evaluation comes to network structure, dynamic model should be extended to network form, which will be the next research direction.

Keywords: 2D numerical simulation; termal dischage;temperature;coastal area.

Abstract: A two-dimensional depth-average temperature transport model was used to simulate the temperature diffusion and dissipation. It is done to analyze the temperature distribution under different cases. The results indicated that the general temperature rise (refer to present, the same as following) of the intakes is below 0.3℃ in Case 2\3\4\5, and the max is 0.78℃ in Case 1. According to the survey temperature at the project intake at present, it is 29.7℃, then the total temperature after the project is below 30.5℃. So the project is feasible for the water temperature.

1 Introduction

In water engineering fields, research on turbulent tidal flow and heat transport in coastal water is important for the purpose of solving the pressing problems involved in water resources, water quality, environmental protection and engineering design, etc[1-3]. The typical coastal water industrial background of the study for heat transport problems concerned in this paper is that the large-sized thermal/ nuclear power stations are frequently built in coastal zones or offshore areas near coastal water[4-5]. As an example, the project is situated at a bay in Indonesia.There are some existing outfalls and intakes presently in this sea area where the project being built locates in (Fig.1). The intakes of K1, K2, K3, K4 and POPKA, are mainly in north of this bay, and the outfalls is in south of the bay. The outfall and intake of KMI and KPI locate west of the project.The project needs to construct on 14,500 DWT coal import berth, one 8,000 DWT ash export berth, two 10,000~20,000 DWT liquid chemical berths, the water intake/outfall and other relevant facilities. According to the design parameter such as discharge volume, outfall water temperature provided, there are some cases of cooling water volume for model test, which is Case 1 (q=100,000m3/h, T=42℃), Case 2 (q=20,000m3/h, T=42℃), Case3 (q=30,000m3/h, T=42℃), Case 4 (q=5,000m3/h, T=43℃), Case5 (q=5,000m3/h, T=35℃).

In this paper, a two-dimensional temperature transport model[6-7] is developed to study the temperature distribution of design intake and other intakes in different cases especially. The model is performed to comprehend the influence of the project on temperature distribution around the sea area.

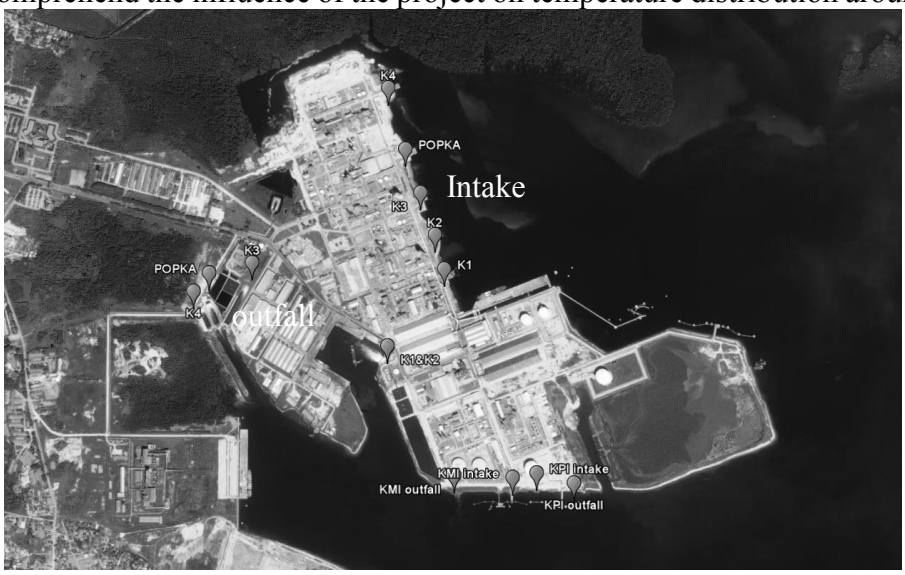

Fig.1 Location of Intakes and Outfalls

2 Mathematic model and setting

The current and cooling water draining advection-dispersion process in project sea area are studied by the plane two-dimensional mathematic model which developed by Danish Hydraulics Research Institute. It has been widely used in lots of projects recent years. The current model includes a continuity equation and two momentum equations. The fundamental equation is:

$$\frac{\partial \varsigma}{\partial t}+\frac{\partial p}{\partial x}+\frac{\partial q}{\partial y}=\frac{Q_s}{A_s} \tag{1}$$

$$\begin{aligned}&\frac{\partial p}{\partial t}+\frac{\partial}{\partial x}\left(\frac{p^2}{h}\right)+\frac{\partial}{\partial y}\left(\frac{pq}{h}\right)+gh\frac{\partial \varsigma}{\partial x}-\Omega q-fVV_x+gp\frac{\sqrt{p^2+q^2}}{C^2h^2}\\&=\frac{1}{\rho_w}\left[\frac{\partial}{\partial x}(h\tau_{xx})+\frac{\partial}{\partial y}(h\tau_{xy})\right]-\frac{h}{\rho_w}\frac{\partial}{\partial x}(p_\alpha)+Q_sU\sin(\Delta\theta)/A_s\end{aligned} \tag{2}$$

$$\begin{aligned}&\frac{\partial q}{\partial t}+\frac{\partial}{\partial x}\left(\frac{pq}{h}\right)+\frac{\partial}{\partial y}\left(\frac{q^2}{h}\right)+gh\frac{\partial \varsigma}{\partial y}-\Omega p-fVV_y+gq\frac{\sqrt{p^2+q^2}}{C^2h^2}\\&=\frac{1}{\rho_w}\left[\frac{\partial}{\partial x}(h\tau_{xy})+\frac{\partial}{\partial y}(h\tau_{yy})\right]-\frac{h}{\rho_w}\frac{\partial}{\partial y}(p_\alpha)+Q_sU\cos(\Delta\theta)/A_s\end{aligned} \tag{3}$$

Temperature advection-dispersion equation：

$$\frac{\partial}{\partial t}(hT)+\frac{\partial}{\partial t}(uhT)+\frac{\partial}{\partial y}(vhT)=\frac{\partial}{\partial x}(h.Dx.\frac{\partial T}{\partial x})+\frac{\partial}{\partial y}(h.Dy.\frac{\partial T}{\partial y})-\frac{KT}{\rho C_\rho}+S \tag{4}$$

Where ς is tide level, means the distance between water surface and datum plane, p, q is unit flux density in the x-direction, y-direction, h is water depth, g is gravitational acceleration, Ω is Coriolis parameter, ρw is water density, pa is atmospheric pressure, C is Chezy resistance number, $\tau_{xx},\tau_{xy},\tau_{yy}$ is component of shear stress in x-direction, y-direction, z-direction, f is wind friction factor, V,V_x,V_y is wind speed and the component in x-direction and y-direction, x,y is orthogonal coordinate, t is time, T is temperature, D_x, D_y is dispersion coefficient, in x-direction and y-direction, U is source discharge speed, $\Delta\theta$ is source discharge angle, S is source strength, $S=Q_s^*(T_s-T_o)/As, To$ is environment temperature, A_s is source discharge area, Q_s is source discharge flux, T_s is discharge temperature, K is sea level heat radiation synthesis coefficient, C_p is water specific heat.

The large and small scope model grids both adopt quadrangle grid, the grid step of the large model is 50m, and that of small model is 10m. The time step for large model and small model is 10s and 2s respectively.The manning resistance parameter, after multi-group debugging ascertained n=0.010～0.015. The diffusion coefficient is 5~15m^2/s according to lots of research results.

3 Numerical simulations and results

According to the design layout and parameters of the project, the water temperature field after the project process is simulated, and the temperature fields at flood and ebb tide are shown in Fig. 2. The water temperature in south of PKT byland is higher than that in north, which is similar to the water distribution at present. Because of the different discharge volume of design outfall in different Cases, there is difference among the Cases. The bigger the discharge volume is, the higher the water temperature is. The temperature of Case 1 is highest, and lowest in Case 4 and Case 5.

Fig.3 is shown the water temperature process in different Case at the CTA intake. From this figure, the water temperature is different during flood and ebb time, which is due to the current movement. The difference from max to the min value is about 0.6 ℃ in Case 1, and 0.1~0.2℃ in other Cases.In order to learn the temperature rise in CTA\KMI\KPI\PKT intake due to the CTA outfall discharge,

Tab.1 is shown the water temperature rise at different location. Compared with water temperature at present, in Case1\Case2\Case3\Case4\Case5, the temperature rise is 0.78℃\0.17℃\0.26℃\0.05℃\0.03℃ at CTA intake; the temperature rise is 1.36℃\0.43℃\0.60℃\0.13℃\0.06℃ at KMI intake; the temperature rise is 1.43℃\0.47℃\0.69℃\0.15℃\0.08℃ at KPI intake; the temperature rise is 0.26℃\0.05℃\0.07℃\0.02℃\0.00℃ at PKT intake.

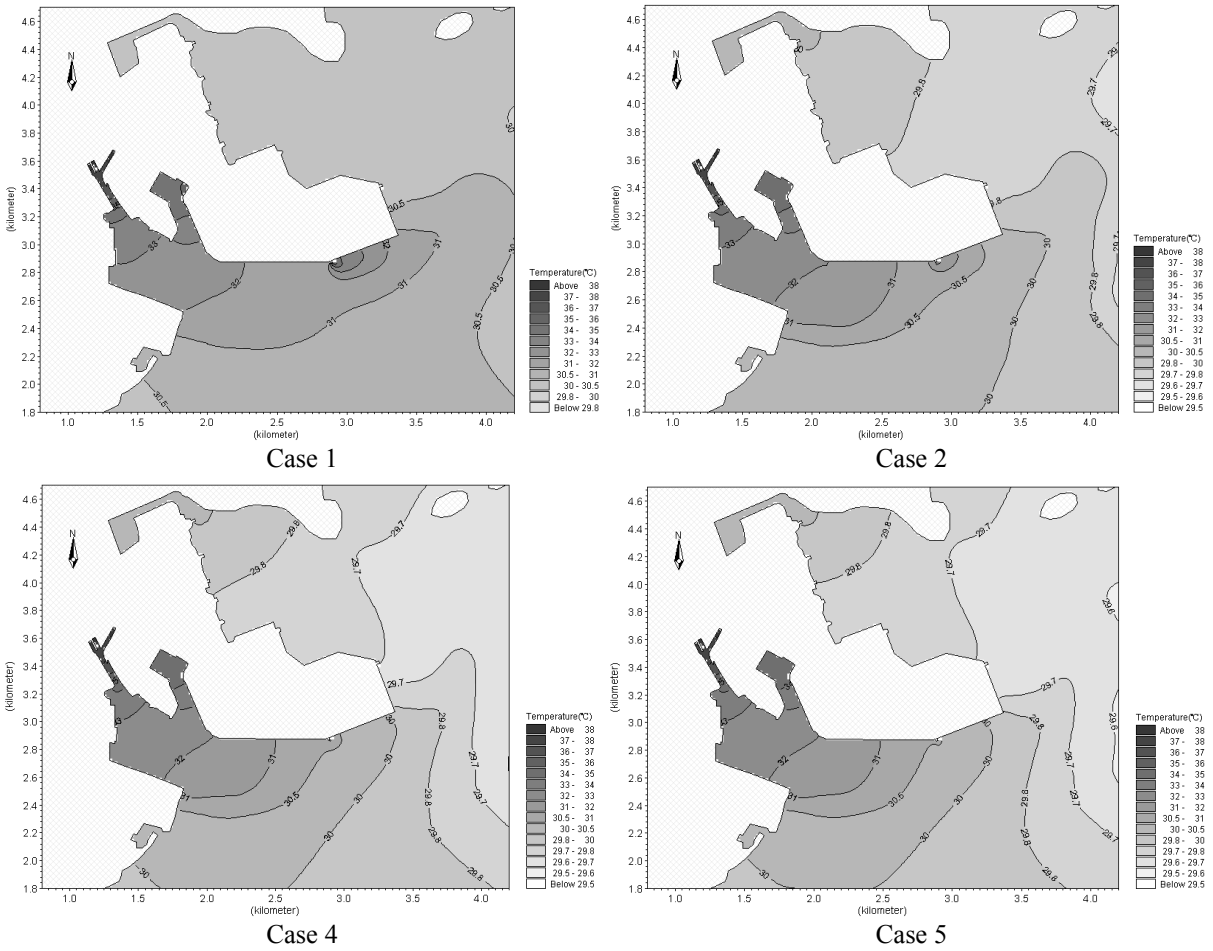

Fig.2 Water Temperature Distribution in Cases(ebb time)

For CTA intake, the general temperature rise is below 0.3℃ in Case 2\3\4\5, and the max is 0.78℃ in Case 1. According to the survey temperature at CTA intake at present, it is 29.7℃, then the total temperature after the CTA project is below 30.5℃. So the CTA project is feasible for the water temperature.For the influence to KMI and KPI intakes, as they are near the CTA outfall, the temperature rise is higher than other intake. However, with the decrease the discharge volume of CTA outfall, the temperature rise becomes lower. Especially, the temperature rise is about 0.1℃ in Case 4 and Case 5, and the value belongs to the simulation accuracy in model, which means that there is no influence to KMI and KPI in Case 4 or Case 5.. In addition, the intakes of KMI and KPI locate in deep water, so there is no influence.For PKT intake, the temperature rise is 0.26 ℃ in Case 1, and the temperature rise is below 0.1 ℃ in other Cases. So there is no influence except for Case 1.

Tab.1 Temperature Rise Compared with Present in different Location

Unit ℃

Design Parameter of CTA	Case	Case 1	Case 2	Case 3	Case 4	Case 5
	Discharge	100,000m^3/h	20,000m^3/h	30,000m^3/h	5,000m^3/h	5,000m^3/h
	Temp of Outfall	42℃	42℃	42℃	43℃	35℃
Location	CTA intake	0.78	0.17	0.26	0.05	0.03
	KMI intake	1.36	0.43	0.60	0.13	0.06
	KPI intake	1.43	0.47	0.69	0.15	0.08
	PKT intake	0.26	0.05	0.07	0.02	0.00

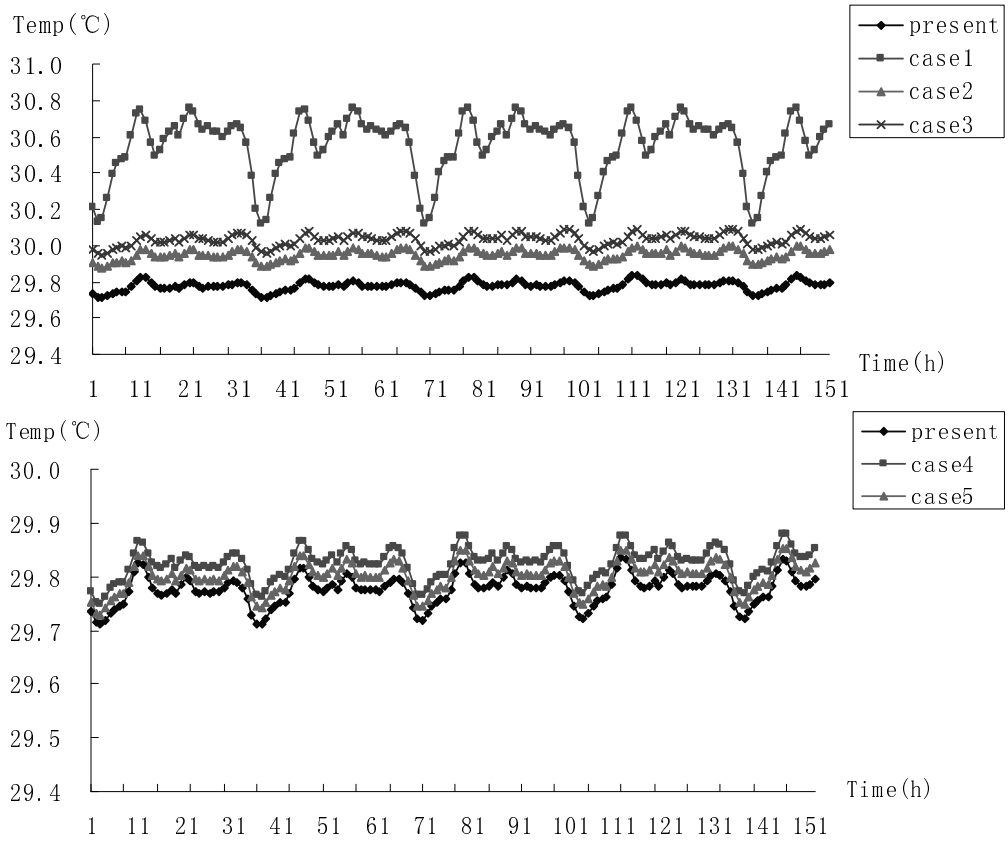

Fig.3 Water Temperature Process in CTA Design Intake

4 Conclutions

Studying by the 2D numerical simulation, the result showed that the project locates in a bay, at the mouth of which there are shoals and two channels, and the south is main channel of water exchange. The bay is divided two parts by the PKT factory area that likes a "byland" that make the water of two parts exchange rarely.The general temperature rise (refer to present, the same as following) of the intakes is below 0.3℃ in Case 2\3\4\5, and the max is 0.78℃ in Case 1. According to the survey temperature at the project intake at present, it is 29.7℃, then the total temperature after the project is below 30.5℃. So the project is feasible for the water temperature.

Keywords: 3D numerical simulation; dredger; current force; settlement.

Abstract: A 3D-dimensional numerical simulation on the process of dredger under current force was carried out by using the finite element software ABAQUS, which is one of the most advanced nonlinear finite element softwares in the world.The interaction between the dredger and the seabed soil foundation is complex and the calculation considering the elastic-plastic property of soil belongs to strong nonlinear problem.The results indicated that the settlement of the dredger increase largely in the first times and the settlement tended to be stable with the times increasing. The stable value is 0.069 meters.

1 Introduction

W. D. Fairway suction dredger, normally working in the expended zone outside the main channel of Tianjin port at about 12:55 on March 8, 2007, was collided at the middle of its larboard with a Super-Large Container MSC JOANNA who was departing from the port. Bad damage induced the seawater to enter her several compartments and W. D. Fairway sunk. The location where W. D. Fairway suction dredger sunk lay in the sea area outside the deep trough of Caofeidian, where there is a rapid flow velocity caused by the flow and the sediment movement (Fig.1.The remote sensing image provided by the China-Brazil earth resources satellite on April 8, 2007). For the reappearance of the dredger sinking state, the simulation calculation about the buried depth of the wreck is studied in this paper.

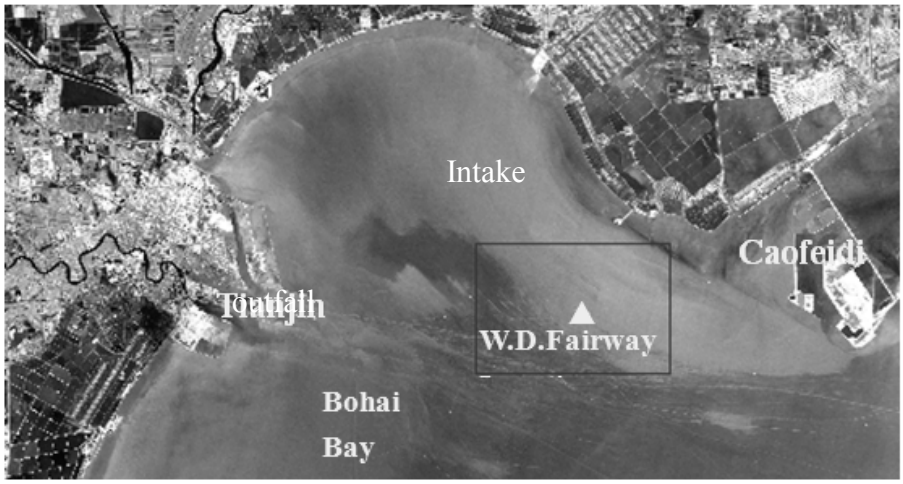

Fig.1. Location of W. D. Fairway suction dredger in the remote sensing image of the China Brazil earth resources satellite on April 8, 2007.

2 Study area and requirement

W. D. Fairway is the largest suction dredger at the present time, built in 1997 and accepted lengthening transformation in 2003 with details as follows: principal dimensions: Loa232.35m ×B32m×D16.85m×mTid- 13.65m, gross tonnage: 33423t, full-load displacement: 82910t, empty weight: 23112t, and deadweight tonnage: 59798t.When the dredger was tilted towards one side, the angle of the bow direction is about 299 degree, the left tilted angle is about 20 degree.The report numerically simulates the settlement volume and the settlement process of the submarine wreck under

the actions of the deadweight load, current load including the dynamical settlement of the wreck under the deadweight load, the wreck settlement of reciprocating current load, the wreck settlement caused by consolidation of softening soil, as well as the impact of seabed scour on the wreck settlement.

The result from the calculation and analysis of the tidal current in the wreck-zone shows that velocities and directions between ebb-tide and flood tide in the water zone occurs some changes. Usually, the flow-velocity in the direction of perpendicular to the hull is smaller, however, bigger crosscurrent maybe engendered in a shorter time. The current around the bow forms a circle flow, though its speed is not high.According to the related data, the chosen speed of the wreck zone is 1.5m/s.

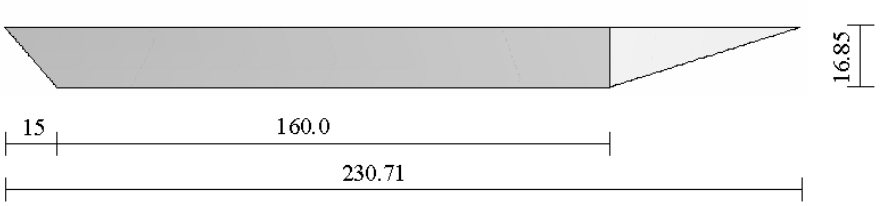

Fig.2. Elevation view of the hull numerical model (m)

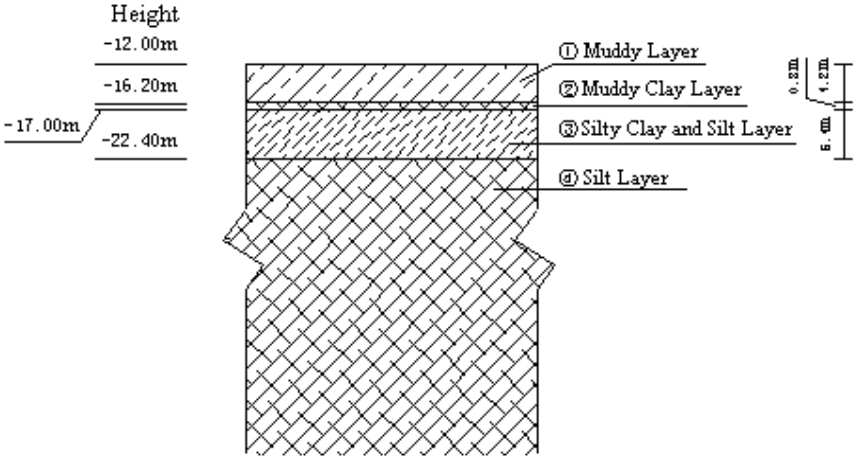

Fig.3. Profile chart of the chosen layer

3 Mathematic model and setting

In the report the numerical simulation was carried out by using the finite element software ABAQUS, which is one of the most advanced nonlinear finite element softwares in the world[1]. In order to simulate the coupling interaction process between the dredger and soils under deadweight, a 3D elastic-plastic finite element dynamic model is established and the explicit dynamic finite element method is used. Meanwhile, the contact surface is set up between the dredger hull and and the soils.

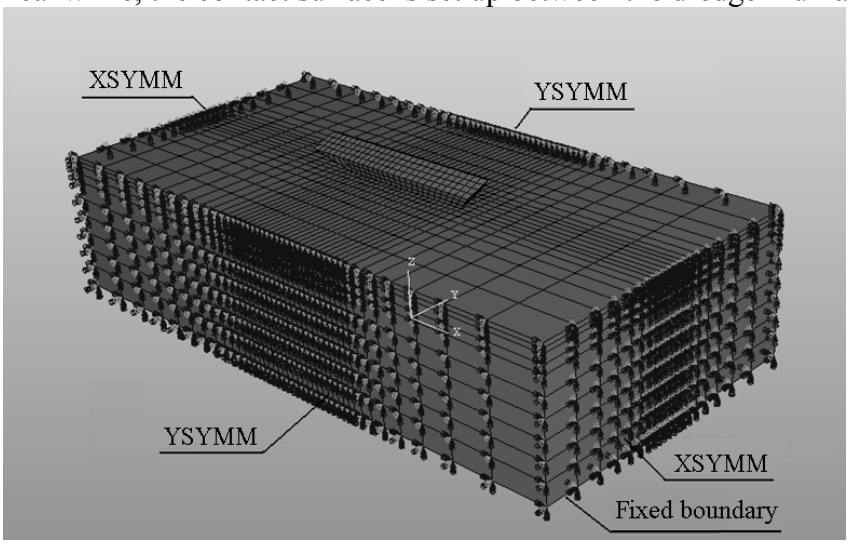

Fig. 4 Boundary conditions of calculation model

Plane graph of the calculation model is shown in Fig.2. The dimension of selected soil region in the direction of the dredger length is 692.13 meters, which takes three times of the dredger length L. The dimension in the perpendicular direction of the dredger length is 352 meters, which is eleven times of the dredger breadth B. The depth of the selected soil region is 160 meters, which takes five times of the dredger breadth B. The distribution of soil layers is as follows: silt layer with thickness 4.2m, muddy clay layer with thickness 0.8 m, silty clay layer with thickness 5.4m and silt layer with thickness 5.4m, as shown in Fig.3. The soil parameters in each soil layer are shown in Table1. The elastic modulus of each soil layer takes 10 times of the compression modulus of the soil layer in the calaulation.

4 Numerical simulations and results

4.1 Current force

The current force on the dredger is calculated according to the professional standard of P R China—Load Code for Harbor Engineering (JTJ215-98). The current force F_W is

$$F_W = C_W \frac{\rho}{2} V^2 A \qquad (1)$$

In which, F_W is the standard value of current force (kN). C_W is the current resistance coefficient. V is the design velocity of current which can adopt the biggest mean current velocity in the range of harbor engineering structures. ρ is the density of water, and it is 1.0 for freshwater and 1.025 for seawater. A is projected area of calculation component in the perpenticular plane of current (m^2).

According to the relevant regulations, the current resistance coefficient of the dredger can be calculated as a rectangular beam and the influence coefficient of submerged depth n_1 can be taken as 0.7. The current resistance coefficient is

$$C_W = 2.32 \times 0.7 = 1.624 \qquad (2)$$

According to the relevant tidal current data, the design velocity of current can be taken as 1.5 m/s and the corresponding current force F_W is

$$F_W = C_W \frac{\rho}{2} V^2 A = C_W \frac{\rho}{2} V^2 \times \frac{1}{2} \times h \times (L_B + L_{Surf}) \qquad (3)$$

In which, L_B is the length of hull bottom surface; L_{Surf} is the length of hull at water surface; h is water depth. Then,

$$F_W = 1.624 \times \frac{1}{2} \times 1025 \times 1.5^2 \times \frac{1}{2} \times 12 \times (160 + 208.85) = 4144.417kN \qquad (4)$$

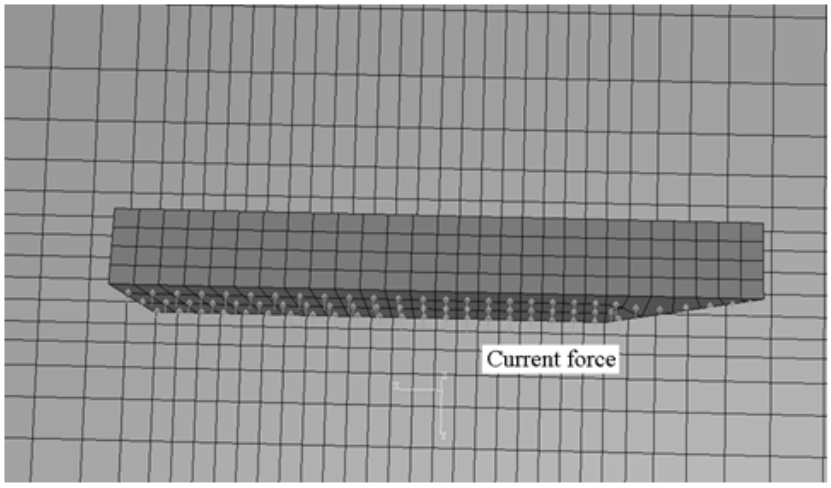

Fig.5 Current force on dredger

4.2 Calculation method

The dredger stranded as long as 33 days. Moreover, the interaction between the dredger and the seabed soil foundation is complex and the calculation considering the elastic-plastic property of soil belongs to strong nonlinear problem[2-5]. So if considering the current force on the dredger as a

dynamic load varying with time, it is unpractical under the current computer efficiency. In the simulation, the cyclically static calculations are adopted. That is, the current force, taken as a constant value, is applied on one side of the dredger and gained a settlement, and then the current force is applied on other side of the dredger and gained a new settlement. The procedure is repeated until the settlement reaches a stable value. With this procedure, The settlement curve of the dredger varying with action times of the current force is obtained, in which one time of the current force direction change is considered as one time of the current force action. In the simulation, N-R method, which is a changing stiffness iteration method, is adopted. In N-R method, stiffness matrix is regenerated at each iteration and it has better convergence than the constant stiffness matrix method, so the integration time step can be taken as a longer value. In the simulation, the current force on the dredger in shown in Fig.5.

4.3 Settlement of dredger under current force

The settlement curve of the dredger under current force is shown in Fig. 6. It can be seen that the settlement of the dredger increase largely in the first times and the settlement tended to be stable with the times increasing. The stable value is 0.069 meters.

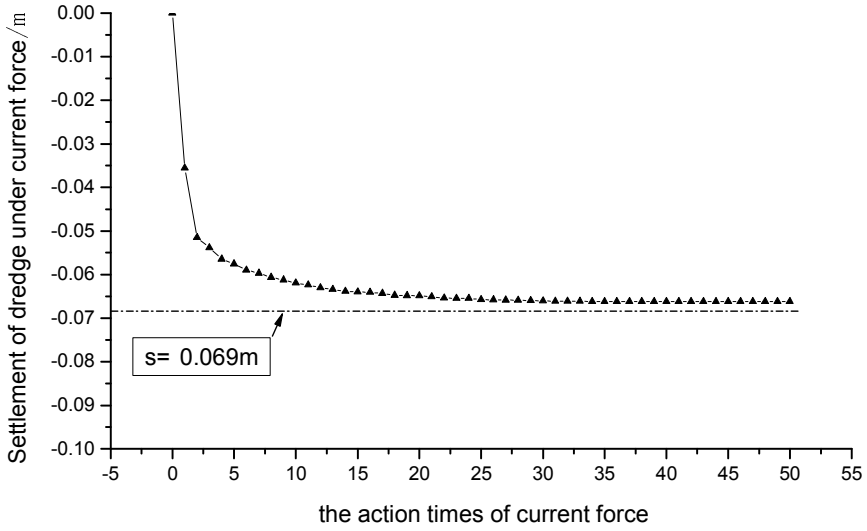

Fig. 6 Settlement curve of dredger under current force

5 Conclutions

Based on the 3D numerical simulation of ABAQUS, which is one of the most advanced nonlinear finite element softwares in the world, the settlement process of dredger under the current force was studied.The interaction between the dredger and the seabed soil foundation is complex and the calculation considering the elastic-plastic property of soil belongs to strong nonlinear problem.The results indicated that the settlement of the dredger increase largely in the first times and the settlement tended to be stable with the times increasing. The stable value is 0.069 meters.

The effect of enterprise business process reengineering fuzzy comprehensive evaluation

Song Ling, Chuanyu Ye

Water conservancy and Environmental Sciences China Three Gorges University Yichang China

Keywords: Process reengineering; Analytic hierarchical model; Fuzzy evaluation

Abstract. This paper analyzed the mechanism of the Enterprise business process reengineering(BPR) to study the performance of the development process, Determined the importance of process cost, process, quality, customer satisfaction to process performance, and on this basis, further established the effect factors layer of process reengineering evaluation index system and build the enterprise develop business process reengineering effect evaluation system. Finally, this article determine the weight of each evaluation index based on the attribute hierarchical model and empirical analyses by using fuzzy comprehensive evaluation method.

Introduction

Implementing BPR is a dynamic process of a enterprise towards the best approximation performance evaluation. It can help enterprise found the problems existing in the process of implementation BPR and make the enterpris obtain advantage in the fierce market competition.

Kuwairi spoke highly the important role of the performance appraisal in the process of BPR implementation and continuous improvement, etc. [1] BPR evaluation directly affects the objectivity of the evaluation results and effectiveness. Zhang Yunbo[2], Zhang Xinli[3] , Zhaoqian[4] , LinJian[5] and YangYang[6] etc research on evaluation index has achieved some results. In addition, research on evaluation method, the current use more includes data envelopment analysis (dea) method, analytic hierarchy process (ahp), grey clustering evaluation method, fuzzy comprehensive evaluation method, etc.

This paper designs the evaluation index system of enterprise BPR effect, by using the analytic hierarchical analysis model Determine the index comprehensive weights of factors layer, and Fuzzy comprehensive evaluation the effect of enterprise business process.

Building process evaluation index system

According to the principle of evaluation index system construction and reference for BPR evaluation index this paper establishes the BPR evaluation index system as shown in table 1.

Table 1 Effect of BPR evaluation index

target layer	rule layer	factors layer
the evaluation of business process (E)	the cost of the process (C_1)	the process cost of process (C_{11})
		resource cost (C_{12})
	the quality of the process (C_2)	percent of pass (C_{21})
		rejection rate (C_{22})
		rework rate (C_{23})
	customer satisfaction (C_3)	the satisfaction of timely delivery (C_{31})
		the satisfaction of price(C_{32})
		ratio of the warranty (C_{33})
		the ration of timely solve problem (C_{34})
	the efficiency of the Process (C_4)	the time of Business process (C_{41})
		the time of activity(C_{42})
		the time of Resource (C_{43})

Based on Analytic hierarchical model's assessment of BPR effect

Analytic Hierarchical Model is a new method for treatment of multiple attribute decision making put forward by professor Cheng Qiansheng based on analytic hierarchy process, it can effectively quantized the unfavorable quantitative variables to measure the objective event.Compared with the analytic hierarchy process AHM's requirements for consistency is lower, and consistency can be tested in the attribute judgment matrix. This paper USES AHM combined with fuzzy comprehensive evaluation method to study the effect of enterprise BPR, by using the attribute hierarchical model to determining the evaluation index weights of development process, and based on this, using the fuzzy comprehensive evaluation method to judge the comprehensive evaluation value of development enterprise BPR effect affected as The change of the various factors.

1. **Based on the AHM to determine evaluation index weights**

(1) Build the evaluation index system of BPR

(2) Constructing judgment matrix

Assignment the 1 ~ 9 scale according to the Satty put forward and constructing judgment matrix [7].

(3) Turn the judgment matrix into attribute measure matrix, and conversion formula is:

$$u_{ij}=\begin{cases}\dfrac{2k}{2k+1}\cdots a_{ij}=k.0.5\cdots a_{ij}=1, i\neq j\\ \dfrac{1}{2k+1}\cdots a_{ij}=\dfrac{1}{k}.0\cdots a_{ij}=1, i=j\end{cases}$$

(4) Judgment the consistency of the attribute matrix according to the following formula

Make $g(x)=\begin{cases}1, x>0.5\\ 0, x\le 0.5\end{cases}, I_i=\{j: g(u_{ij})=1, 1\le j\le n\}$

The sufficient and necessary condition of attribute judgment matrix u_{ij} has consistency is for any i, when I_i is not empty meet: $g(u_{ik})-g\left(\sum_{j\in I_I} g(u_{jk})\right)\ge 0, 0\le k\le n$

(5) Calculate the weight of each index

Calculate rule layer to tagert layer, as well as the factors layer to upper, namely the relative weight vector of the criterion layer is: $W_i=\dfrac{2}{N(N-1)}\overline{W}$ Among them $\overline{W}=\sum_{j=1}^{n}\bar{u}_{ij}$, $j=1,2,\cdots,n$, i is the number of elements in the layer.

(6)calculate the synthesis weights of the i layer to the j layer. $w_{ij}=(w_{i1}, w_{i2}, \cdots, w_{in})$

2. Using the fuzzy comprehensive evaluation method evaluation the effect of process reengineering.

(1) Certain factor set

Assumes that the evaluation object have n kinds of properties, and set each attribute of impact assessment object for c_i, and the set composed by n factors callde factor set, remember to $C=(c_1, c_2, \cdots, c_n)$.In this article $C=(c_{11}, c_{12}, c_{13}, c_{21}, c_{22}, c_{23}, c_{31}, c_{32}, c_{33}, c_{41}, c_{42}, c_{43})$.

(2) Determine the comment set

The results of fuzzy comprehensive evaluation described by fuzzy set v_j, the set component with various kinds of evaluation results called comments set V, and $V=(v_1, v_2, \cdots, v_m)$. v_j mean comments at all levels from high to low. In this paper, given $V=(v_1, v_2, v_3, v_4, v_5, v_6)$ and respectively is very good, very good, better, general, poor, very poor. Full points for 100 and Corresponding set of points is $F=(f_1, f_2, f_3, f_4, f_5, f_6)=$（100-90，89-80，79-70，69-60，59-50，49-0）.

(3) Determine the evaluation matrix

Suppose the membership degree of factor c_i to factor v_j of the Comment set is r_{ij}, the evaluation of factor c_i to things is: $r_i = \left[\frac{r_{i1}}{v_1} \quad \frac{r_{i2}}{v_2} \quad \cdots \quad \frac{r_{in}}{v_n}\right]$

r_i is fuzzy evaluation set of comment set V and Shorthand for $r_i = (r_{i1}, r_{i2}, \cdots, r_{im})$, it reflects the degree of take comments v_j of things to factor c_i.

Assume that in the evaluation of the BPR effect of an enterprise, to the process cost experts give the proportion of evaluation very good, good, better, general, poor, very poor 45%，20%，15%，10%，5%，5% respectively, and $R_1 = (0.45, 0.20, 0.15, 0.10, 0.05, 0.05)$ as the evaluation set of the change of process reengineering process cost to the function of enterprise business process performance index.

The fuzzy comprehensive evaluation matrix formed by the single factor evaluation set is: $R = \begin{bmatrix} r_{11} & r_{12} & \cdots & r_{1m} \\ r_{21} & r_{22} & \cdots & r_{2m} \\ \vdots & \vdots & \vdots & \vdots \\ r_{n1} & r_{n2} & \cdots & r_{nm} \end{bmatrix}$

（4）Comprehensive evaluation

Actually evaluation matrix is a fuzzy relationship of set M and evaluation, given a fuzzy relation R of U to V, and considering the weight of each evaluation factor W will get the comprehensive evaluation of each evaluation index. Namely: $A = WR$

（5）The evaluation index processing

According to the principle of maximum membership degree, turn the fuzzy subset A into specific evaluation results. The determination comments of evaluation objects as follows: $a = \max_{1 \le i \le m} \{a_i\}$

Case analysis

Use AHM fuzzy comprehensive evaluation method to analyze and evaluation an enterprise BPR effect

（1）Using the AHM determining weights of evaluation indexes

According to the calculation results, the weight coefficient of rule layer respectively: $_1$=0.446, w_2=0.327, w_3=0.173, w_4=0.054

The Comprehensive weight coefficient of factors layer respectively: w_{11}= 0.064, w_{12}=0.382,w_{21}=0.193,w_{22}=0.109,w_{23}=0.025,w_{31}=0.053,w_{32}=0.078,w_{33}=0.009,w_{34}=0.033, w_{41}=0.006, w_{42}=0.018,w_{43}=0.03

（2）Build a fuzzy evaluation matrix

According to experts on research development process reengineering leads to resource changes and the scores of process performance indicators to improve get fuzzy comprehensive evaluation matrix: R

(3) Fuzzy subset: $A = WR = [0.347 \quad 0.337 \quad 0.110 \quad 0.100 \quad 0.100 \quad 0.005]$

So, the reconstruction effect of the enterprise research development process have a good memnbership for v_1，according to the principle of membership degree maximum ，the effect of the research development process reengineering of this enterprise is very good.

A New Highway Safety Model based on Cellular Automata

Li Lixing

Department of electric power engineering, North China Electric Power University, Baoding, China

Email: lilixing123123@gmail.com

Keywords: traffic flow, Cellular automata, danger index, safety evaluation

Abstract: With the growth of the total mileage of highway. There is great importance in studying highway safety. At the present time, there are little research on traffic safety with the consideration of the Keep-Right-Except-To-Pass Rule, which requires drivers to drive in the right-most lane unless they are passing another vehicle. Based on Cellular Automata, this paper constructs a new model of highway safety with the consideration of the particular Rule. To evaluate the safety of the road, the model proposes a new index based on energy conservation law. After the simulation, the result shows the best traffic density to balance the safety and traffic flux is 20.1133veh/km.

1 Instruction

With the development of the infrastructure in china, total mileage of highway is increasing rapidly. In China, multi-lane highways often employ a rule that requires drivers to drive in the right-most lane unless they are passing another vehicle, in which case they move one lane to the left, pass, and return to their former travel lane. The influence of this rule is rarely mentioned in current study. There is practical significance in construct a traffic model in this particular rule.

Cellular automata model is a powerful tool to solve the problem of nonlinear in recent years. It can simulate the complex phenomenon with simple rules, and easily to implement on computer. As a consequence, it gets rapid development and extensive application, and it is more and more important in guiding the optimization of traffic flux [1-3]. This model can simulate the traffic condition in particular rules perfectly.

2 Modeling

The model defines a two- lane discrete cellular chains that are one dimensional to indicate a two-lane freeway, and there are 250 cells in each discrete cellular chain.

If each cell's actual length is 6m, then the simulation of the actual path length is 1500m. The road is divided into cells which can be either empty or occupied by a car with a velocity. A matrix represents those cellular chains in the programming.

Inspired by the Nagel and Schreckenberg model (NaSch) established in [4-5], we set 4 rules in this model. There are acceleration rule, lane changing rule, deceleration rule, randomization rule and position update rule.

As for acceleration, the vehicle's speed v_n is shown in (1).the driver drives on the former travel lane under the original speed, and always make it first choice.

$$v_n \to \min(v_{\max}, v_n + 1) \tag{1}$$

As for lane changing rule, if the vehicle meet these following demands , but can't accelerate ,he or she will chose to change lane, and then must return to his former lane.

$$\begin{aligned} &d_n < \min(v_n + 1, v_{\max}) \\ &d_{n,other} > d_n \\ &d_{n,back} > d_{safe} \end{aligned} \tag{2}$$

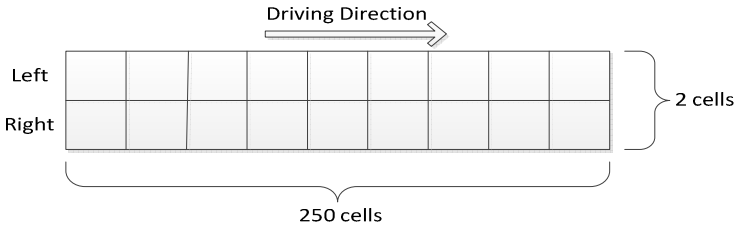

Fig.1 A two-lane cellular freeway

As for deceleration, the vehicle's speed is shown in (3). The driver have no choice but to decelerate on the former lane.

$$v_n \to \min(v_n, d_n) \tag{3}$$

As for randomization, the vehicle's speed is shown in (4). Considering the accidental factor of the driver. Every vehicle on this freeway will decelerate with probability p.

$$v_n \to \max(v_n - 1, 0) \tag{4}$$

As for position update , the vehicle's position is shown in (5). And the model updates the status vehicle by vehicle.

$$x_n \to x_n + v_n (n \to n+1) \tag{5}$$

Under the rules of the above five, the car's speed and position will change with time. But the speed of the car always less than the maximum speed limit.

There are running lane (slow lane) and overtaking lane (fast lane) in a two-lane freeway. The orders to execute these rules are different in two lanes. The difference is shown in fig.2

These factors describe the freeway traffic performance: traffic performance f , traffic safety D and the vehicles average passing time t . They can be used to describe the traffic performance.

3 Danger index

The model use the danger index to evaluate the safety of the freeway. It is inspired by energy conservation law. Since we assume all vehicles are identical, the lost energy E is a function of speed v.

$$E = \frac{1}{2} m v_1^2 - \frac{1}{2} m v_0^2 \tag{6}$$

Where v_1 is the speed after declaration and v_0 is the speed before declaration. And we define the danger index of a single vehicle as equation (7).

$$h_n = v_1^2 - v_0^2 \tag{7}$$

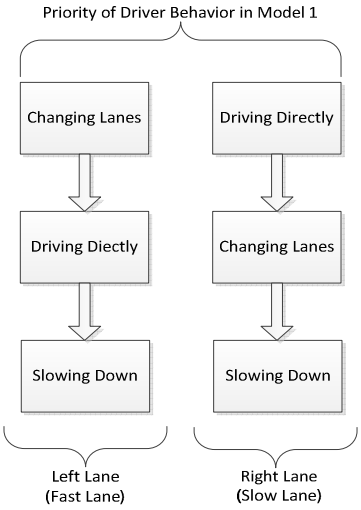

Fig.2 The priority of the left lane and right lane

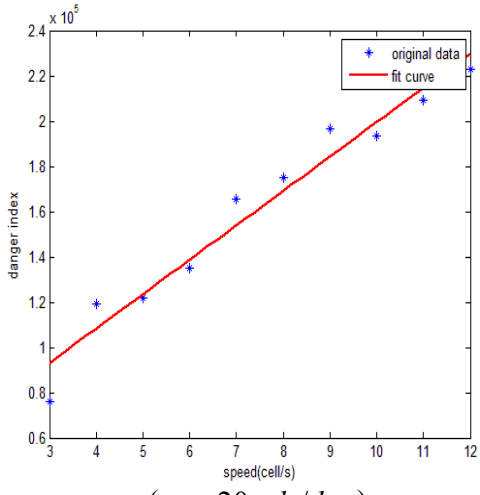

($\rho = 20veh/km$)

Fig.3 Danger index in different speed limit

Where v_1 and v_0 has the same definition as it referred above. Where h_n denotes danger index of a single vehicle. The sum of h_n from one freeway in an hour is this freeway's danger index D.

$$D = \sum_{t=1}^{3600} \sum_{n=1}^{N} h_n \tag{8}$$

N is the whole number of vehicles on one freeway.

Therefore, we establish model 1, and its programming course can be seen in the following diagram.

4 Analysis of the model

Danger index in different speed limit. As we can see in Fig.3, the danger index trend to increase when we raise the speed limit.

When traffic density is fixed, the number of vehicles N is also fixed. The freeway's danger index D is determined by every single car's danger index h_n. The density we use in our simulation is $\rho = 20veh/km$ which indicates light traffic. The gap between vehicles is big enough. In most condition, the driver only need to slow down 1cell/s. The calculation of a single vehicle is shown as following:

$$h_n = v_n^2 - (v_n - 1)^2 \tag{9}$$

$$h_n = 2v_n - 1 \tag{10}$$

We can see a liner relationship between h_n and v_n. Just like the figure.

Factors that affect the traffic flow. The Fig.4 indicates that when the traffic density lower than optimal traffic density, the vehicle is in 'free driving' state, which means cars can drive with only slight deceleration. Average velocity will be high. And the traffic performance will soar with density increasing. After traffic density exceeding the optimal traffic density, the car-following phenomena appears on the freeway. The speed is restricted. The traffic performance will decrease with density increasing. The highest traffic performance appears when density reaches the optimal point.

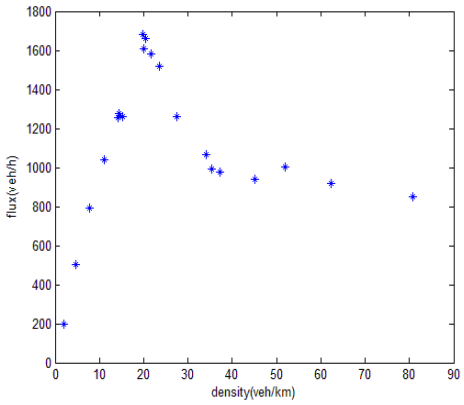

Fig.4 Traffic flow in different density

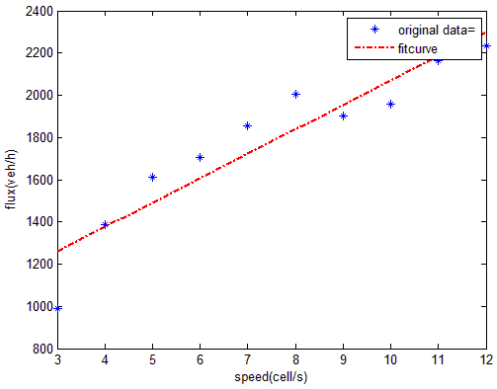

Fig.5 Traffic flow in different speed limit

Fig.5 shows the relationship between speed limit and traffic performance. It's obvious that traffic performance is proportional to speed limit.

According to the analysis, the greatest traffic performance is this:

$$f_{\max} = \frac{3600\rho L}{1000\dfrac{L}{6v}} \tag{11}$$

Where $f_{\max}$ is traffic performance, v is speed limits and ρ is traffic density. The relationship between traffic performance and speed is linear, as we can see in fig.5. And the data are all lower than their extreme value. Such as when v=3 cells/s, the traffic flux shows below 1296veh/h which it is 1003veh/h.

Optimization of traffic flow. The Fig.4 shows that the danger index increases when traffic is denser. That indicates highway safety and traffic flux are contradictory. So it's a problem to find an optimal density to get the best performance of the freeways. Since this model has already quantified the degree of the danger on this freeways, we can change this problem into a multi objective optimization problem.

The Topsis method[6] is used to solve this multi objective optimization problem.

To preform Topsis method, we standardize the data we have obtained by (12).

$$y_n = \frac{x_n - x_{\min}}{x_{\max} - x_{\min}} \tag{12}$$

x is the data we have and y is the standardized data.

After standardization, we make traffic density as abscissa and danger index as ordinate. Since we hope the danger index smaller and the traffic performance greater, we calculate the distance from data point to (0, 1) to find the shortest one. The equation is:

$$I = \sqrt{x^2 + (1-y)^2} \tag{13}$$

Where x is standardized danger index, y is standardized traffic performance and I is distance we called value index. The result shown as Fig.6.

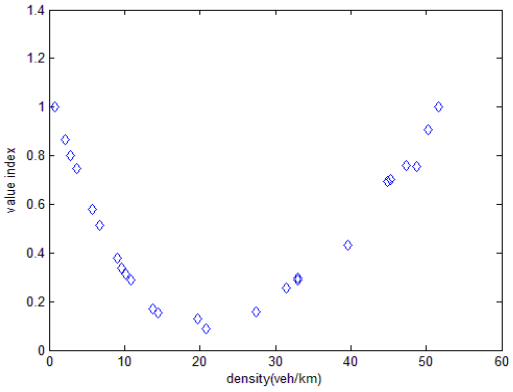

Fig.6 Value index with different traffic density

The smallest value index shows up when traffic near 20veh/km, which is 20.1133veh/km. At this point, the freeway shows smaller danger index which is 10423 and greater traffic performance which is 1608veh/h.

5 Conclusion

Taking into account the impact of Keep-Right-Except-To-Pass Rule, this paper construct a new model of highway traffic based on Cellular Automata. Inspired by energy conservation law, this paper proposes the danger index to evaluate the safety of highway. This model find a linear relationship between danger index and speed limit. Traffic flow and speed limit also has a linear relationship. And the optimal traffic density is 20.1333veh/km.

Keywords: seat allocation; optimization; revenue management; railway transportation

Abstract. Based on the seat inventory control method of revenue management in airline, the author researches the optimization strategy on the seat inventory control in railway passenger transport. The author proposes one optimization model for seats allocation, which is to allocate seats by calculating the value to determine the order of getting seats for each OD under the analysis of the interaction among all trains running on the same rail lines and those trains' demands intensity. The experiment results show that this new model can be used to allocate seats for the train with multiple stations rapidly and appropriately. In comparison with the method without considering the value of each OD, the model based on OD's value can get better results.

Introduction

Revenue management originated in airline of USA in the 1980s, it is defined as selling the right products to the right people at the right price [1]. Inventory control is one of the most important components of revenue management. In railway passenger transportation, seat allocation is just similar to inventory control. China passenger railway network is characterized with many stations, long distances among stations, multiple train type and seat type, which makes it complex to allocate seats. There have been many scholars focusing on seats allocation in China passenger railway. For example, X.M. ZHANG studied seats allocation strategy supposing ticket price is dynamic in China railway [2]. For the case of multi-leg in airline which is similar to railway, Q. GAO established a stochastic programming model to maximize the total revenue, and solved that model by genetic algorithm [3], but it is still complex and is not suitable for large transport network such as China passenger railway. Other papers such as [4] and [5] studied new methods to allocate seats for China passenger railway based on its actual business, but there are some drawbacks in China passenger railway's business that many parameters come from technical staff's set up without computing, so they may not get the maximum revenue through those methods in [4] and [5].

Therefore, we proposed a new model of seat allocation for China railway passenger transport based on OD's priority or OD's value. OD's priority is the result from analysis of the interaction among trains in the same OD and on the same date. Our model can allocate seats efficiently, reducing manual intervention to seat allocation and increasing the total expected revenue.

Algorithm of Calculating OD's Priority

Nowadays dynamic virtual nested strategy is the mainly way used for seat inventory control in airline, which is the combination of virtual nested control and bid-prices control [6, 7]. A bid-price control sets a threshold price, such that a request is accepted if its revenue exceeds the threshold price and rejected if its revenue is less than the threshold price. A virtual nested control allows each ODF (Origin-Destination Fare) to be nested, and it first defines a set of indexes for each leg. The index represents a range of fare which is named as net leg fare [8], and then those companies use EMSR (Expected Marginal Seat Revenue) or other methods to compute booking limit and protect level of each ODF on each leg [9].

Methods of Computing OD's Priority or Value in Passenger Railway. Since ticket price is static in China railway, it is not suitable to set priority for OD using the similar concept based on net leg fare. For rail, since there are so many trains running on the same line and on the same date, while number of running trains is different in different periods. Therefore, this article firstly summarized all available seats of a line, then split one day into several periods, and computed number of seats in each period, finally computed OD's value according to OD's demand intensity.

Assume that there are *n* stations on a line and the interval is Δt, and then there are *n-1* legs, C_n^2 pairs of OD denoted as $OD_j, \mathrm{j} = 1,2,\cdots,C_n^2$, and one day is divided into $\mathrm{T} = 24/\Delta\mathrm{t}$ segments. To analyze influence to seats allocation coming from demand intensity on the same OD in different periods, trains are grouped by their running time $\mathrm{t}, \mathrm{t} = 1,2,\cdots,\mathrm{T}$. Supposing total number of trains running on OD_j is R_j and number of trains on OD_j in period *t* is r_{tj}, then

$$\sum_{t=1}^{T}\sum_{j=1}^{C_n^2} r_{tj} = R_j \quad t = 1,2,\cdots,T; j = 1,2,\cdots,C_n^2 \tag{1}$$

Assume that capacity of all trains running on OD_j is c_j, fare is p_{tj} and the forecasted demand is d_{tj} in period *t*, then total capacity of OD_j *is* $C_{tj} = r_{tj}c_j$, total demand of OD_j is $D_{tj} = r_{tj}d_{tj}$ and total revenue of OD_j is $P_{tj} = p_{tj}d_{tj}$ in period *t* of OD_j on the same date. We denote the contribution of OD_j to the line in period *t* as P_{tj}:

$$f_1(p_{tj}, d_{tj}) = \frac{P_{tj}}{\sum_{j=1}^{C_n^2} P_{tj}} \tag{2}$$

However, if we only use $f_1(p_{tj}, d_{tj})$ to be value of OD_j, risk still exists that influenced the total expected revenue. Since there may exist OD_j that its capacity is large with a little demands, or its demand is large with fewer available seats. So we analyze the relationship between demand and available seats of OD_j, reducing the risk that priority of OD_j with high expected revenue is set extremely high and priority of OD_j with low expected revenue is set extremely low, and we compute one parameter α_{tj} to adjust $f_1(p_{tj}, d_{tj})$ as follows.

$$\alpha_{tj} = \frac{D_{tj}}{\sum_{j=1}^{C_n^2}(D_{tj})} / (\frac{C_{tj}}{\sum_{j=1}^{C_n^2} C_{tj}}) = \frac{D_{tj}(\sum_{j=1}^{C_n^2} C_{tj})}{C_{tj}(\sum_{j=1}^{C_n^2}(D_{tj}))} \tag{3}$$

In Eq .4, α_{tj} is defined as the ratio of demand and seat capacity of OD_j in period *t*, and it represents urgency of demand of OD_j in period *t*. And the adjusted contribution of OD_j to the line in period *t* is defined as shown in Eq. 5. The larger $f(p_{tj}, d_{tj})$, the higher the value or priority of OD_j.

$$f(p_{tj}, d_{tj}) = \alpha_{tj} f_1(p_{tj}, d_{tj}) = \frac{P_{tj}D_{tj}(\sum_{j=1}^{C_n^2} C_{tj})}{C_{tj}(\sum_{j=1}^{C_n^2} P_{tj})(\sum_{j=1}^{C_n^2}(D_{tj}))} \tag{4}$$

Model of Seat Allocation based on OD's Priority

Algorithm Description. Linear programming is often used to solve problems in optimal scheduling, address selection and other industries. In research of revenue management, Williamson studied inventory control strategy in airline by linear programming [10]. Now in railway, to solve the problem of seat allocation by linear programming, assume that the future demand d_{tj} and fare p_{tj} of an OD in period *t* are known and demand of each OD is independent from each other, *n* stations are in a line where exists *n-1* legs and C_n^2 OD, and seat capacity of each train is c_i. We denote number of allocated seats of each OD in period t as x_{tj}. In order to maximum the expected revenue of the whole line under limits of seat capacity, we firstly denote the relationship of each OD and legs as a_{ij}.

$$a_{ij} = \begin{cases} 1, & \text{leg } i \text{ is used by } OD_j \\ 0, & \text{else} \end{cases} \tag{5}$$

And then our model is described as follows.

$$max \sum_{j=1}^{C_n^2}\sum_{t=1}^{T} p_{tj}x_{tj} \tag{6}$$

subject to

$\sum_{j=1}^{C_n^2}\sum_{t=1}^{T} a_{ij}x_{tj} \le Cj$=1,2,$\cdots, C_n^2$; i=1,2$\cdots$n-1 (7)

$\sum_{t=1}^{T} x_{tj} \le d_j$ j=1,2,$\cdots, C_n^2$ (8)

$x_{tj} \ge 0$ (9)

Analysis of Rationality and Optimality. According to the optimal theory, we firstly analyze the first-order necessary conditions of our model. For simplicity, assume that revenue function $r(x_t) = p_t x_t$ is concave, and $\mathcal{J}(x_t) = \partial(p_t x_t)/\partial x_t$ is represented as marginal revenue in period *t*. Then the first-order necessary conditions for the optimal allocated seats x_t^* and λ^* in period t are

$\frac{\partial(p_t x_t)}{\partial x_t} = \lambda^*$ (10)

subject to the complementary slackness condition

$\lambda^*(C - \sum_{j=1}^{C_n^2}\sum_{t=1}^{T} a_{ij}x_{tj})$=0 (11)

and the multiple non-negativity constraint $\lambda^* \ge 0$.

Obviously, according to concave function's feature, the above first-order necessary conditions in Eq. 10 are also the sufficient conditions to get the optimal revenue. Moreover, according to theory of economics, the Lagrange multiplier λ^* has the interpretation as the marginal opportunity cost of each OD's capacity, and Eq. 10 says that the marginal revenue should equal the marginal opportunity cost of capacity in each period, which means that if marginal revenues and costs are not balanced, we can increase number of allocated seats for OD. Eq. 11 says that if number of allocated seats exceeds number of available seats in one OD, the Lagrange multiplier cannot be larger than 0, that is, opportunity cost of OD cannot be larger than 0. If opportunity cost of OD is equal 0, our model is not under constraints, that is, all demands will be satisfied and the max expected revenue is got.

Moreover, when finding the optimal result, the higher level OD with larger value get seats in prior, and the total expected revenue increases as time going, and growth rate of the total expected revenue decreases as OD's value's decreasing. Therefore, we get max value until growth rate of expected revenue is up to minimum.

Experiment Evaluation

We used data of one railway line from present ticketing system, which contains forecasted demands of each OD and trains' schedules. And we got results according to our model in Matlab7.5, assuming that ticketing demands in Poisson process. To evaluate our model's effectiveness based on OD's priority, we allocate seats in two ways, one is based on OD's priority and the other way is not.

Data Description. Trains' schedules are shown in Table 1, and forecasted demands and fare of each OD are shown in Table 2. Each train's maximum capacity is 600 and we divided one day into six periods.

Table 1 Train's schedules

Stations of trains		periods					
ID of train	station	1	2	3	4	5	6
1	ABCDEF	A	B	C	D	E	
2	ABDF		A	B		D	
3	ACEF		A		C		E
4	ACDF			A		C	D
5	ACF				A		C
6	BCDF		B	C	D		
7	BCEF			B	C		E
8	CDEF		C	D	E		

Table 2 Forecasted demands and fare of each OD

OD（No.）	Forecasted demand								fare
	1	2	3	4	5	6	7	8	
A-B（1）	45	85							55
A-C（2）	66		142	145	268				180

D-F（14）	35	53		67		140		150	235
E-F（15）	20		34				100	90	130

Effectiveness Analysis. For the above data, we got the following results no based on our algorithm in TABLE 3, and results based on our algorithm are shown in Table 4. Compare the total expected revenue In Table 3 and Table 4, the former is 75535 less than the latter. And from No.1 to No.8 train, change of each train's total expected revenue from Table 3 to TABLE 4 is -36410, -56090, 2220, 9000, 0, 5745, 0, 0 separately.

Table 3 Results no based on our model

OD	Trains								Allocated seats
	1	2	3	4	5	6	7	8	
A-B	45	85							130
A-C	66		142	145	268				621
A-D	65	53		9					127

C-F	98		116	58	130	210	67	220	899
D-E	30							74	104
D-F	35	53		87		140		150	465
E-F	20		34				100	90	244
Revenue	305890	328450	332280	333140	325750	264420	270390	201350	2361670

Table 4 Results based on our model

OD	Trains								Allocated seats
	1	2	3	4	5	6	7	8	
A-B	45	0							45
A-C	66		142	145	145				498
A-D	88	202		0					290
A-E	50		0						50
A-F	195	398	450	412	455				1910
B-C	32					50	76		158
B-D	50	12				105			167

B-E	145						180		325
B-F	90	190				185	175		640
C-D	19			0		90		100	209
C-E	0		0				67	156	223
C-F	113		150	188	130	210	178	220	1189
D-E	0							74	74
D-F	7	12		0		140		150	309
E-F	20		0				100	90	210
Revenue	342300	384540	330060	324140	325750	258675	270390	201350	2437205

The above results shows that if seat capacity is enough for all passengers' demands, both two methods can get the same expected revenue obviously; if under capacity constraints, using our model may not get more expected revenue, but the total expected revenue is much larger than the linear programming model no based on OD's priority. Therefore, our model is more effective than the simple linear programming model.

Conclusions

This article proposed a new model to allocate seats for a line in China passenger railway, which considered the interaction of all trains running on the same OD according to those trains' demands, schedules and seats capacity. Using our model can get larger expected revenue under constraints, which is through the way that replaces the mean demand μ_j to the deterministic demand d_j of each OD to concern to demands' uncertainty. However, according to Littlewood's opinion, if we considered a passenger's uncertainty in his booking process, we will get larger expected revenue [11, 12]. Moreover, when there are fewer stations on a railway line, the computational complexity according to our model is small, but it becomes very large when many stations exist on a railway line. Therefore, we should research further to increase the total expected revenue considering demands' uncertainty and find other optimal algorithms to solve our model.

Keywords: cloud computing; mutual authentication; security communication; data sharing; IBE

Abstract. In Recent years, the rapid development of cloud computing promotes the technological innovation. In the meantime, the security of cloud attracts many researchers. In this paper, a security architecture is proposed to provide a trust communication mechanism between entities in the cloud. Based on this security architecture and BFIBE, three security protocols are proposed to implement mutual authentication and key agreement, which can resist man-in-middle attacks and masquerading attacks. Besides, based the three protocols, an effective data sharing method is proposed.

1 Introduction

In recent years, various companies have established their own cloud systems in different countries. These cloud systems can be divided into public cloud, private cloud, hybrid cloud. In the public cloud systems, cloud servers can provide services for any legitimate user. So communications between the cloud entities will face a variety of threats. It is necessary to establish a security mechanism to protect the security of communications between cloud entities. This paper presents a security architecture based on the identity-based cryptography (IBC). And on this basis, three authentication protocols are proposed to achieve mutual authentication and secure data sharing.

The structure of this paper is as follows:

The first part is an introduction, and the second part is related work, and the third part is to describe the security architecture and related definitions, and the fourth part is about the mutual authentication protocols and data sharing methods, and the fifth part is about the experiment and the analysis of the results, and the first six section is a summary.

2 Related Work

Shamir [1] proposed an identity-based cryptography (IBC) in 1984, and Boneh et al. [2], proposed the first truly practical IBE scheme in 2003. In a large network, it is difficult to handle all the authorized certification with only one PKG. Therefore, Gentry et al. [3] proposed a practical hierarchical identity based encryption scheme (HIBE). The scheme is mainly to solve the problem of entities registration and private keys generation in HIBE. Boneh and Boyen [4,5] constructed an another HIBE in 2004 and redefined it in 2011[6].

In the field of cloud computing, Schridd et al. [7,8] hired only one PKG to provide services for the entire cloud system of which the security has not been proven. Based on HIBE scheme, Li et al. [9] proposed a hierarchical architecture for cloud computing and a TLS-analogous authentication protocol. But the system is complex and the amount of calculation is too much. Kang and Zhang [10] proposed an identity-based authentication scheme for cloud storage sharing. However the low-level PKGs do not reduce the burden of root PKG in their scheme. And the data sharing is limited in the same domain. Cao et al. [11] proposed a layered cloud security architecture and three authentication protocols based the architecture for the federated cloud system. But the authentication between PKGs is complicated.

Because of the amount of calculation is huge in HIBE scheme, therefore this paper constructs a layered architecture based on the architecture of Cao [11]. In this structure, the low-level PKGs effectively alleviate the burden of root PKG. And under the help of root PKG, users are able to authenticate and share data in the entire cloud system. It overcomes the limitation of data sharing in the scheme of Kang. Based on the architecture, the paper designs three identity-based authentication protocols and provides a method for data sharing in the cloud system using the three protocols. Compared with the agreements in the scheme of Cao, the authentication between PKGs and entities in the same domain is non-interactive in this paper. So it simplifies the process of authentication and improves the efficiency of the user data sharing and authentication.

3 System Architecture

3.1 Security Architecture. As shown in Fig.1, the security architecture adopts layered structure. In this system, the root PKG (RPKG) is responsible for the registrations of low-level PKGs and generating private keys for them. In practice, we divide the system into many domains. Each contains a low-level PKG and a user set and cloud servers. Low-level PKGs responsible for the registrations of entities in their domains and generating private keys for them. Low-level PKGs have two private keys. One is generated by RPKG used to communicate with PKGS and the other is generated by himself used to communicate in his domain. If there are not special explanations, the following "PKG" refers to "low-level PKG".

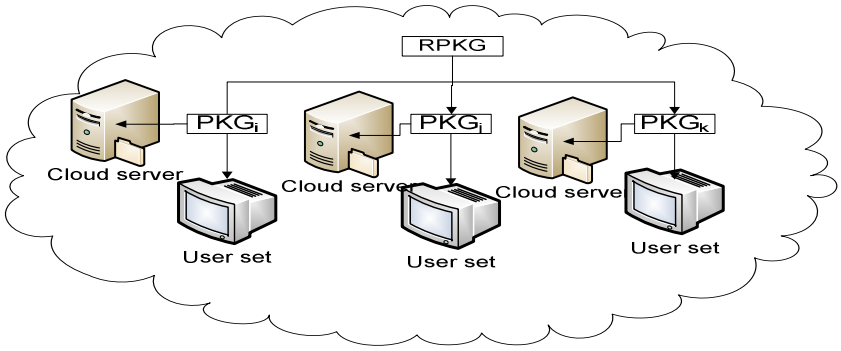

Fig. 1 The layered security architecture

3.2 Cloud Entity Authorization.

3.2.1 PKG Authorization. PKGs provide their identifiable information ID_{pkg} to RPKG. Then RPKG generates a public key $Q_{pkg}=(ID_{pkg},T)$, where T is a date representing for the valid period. RPKG computes $K_{pkg}=G(S_{rpkg},Q_{pkg})$, where$K_{pkg}$ is the private key of PKG, and S_{rpkg} is the master key of RPKG. G() is the private key extraction algorithm of BF-IBE[2]. RPKG generates a tuple $V=(K_{pkg}, P_{rpkg},Q_{rpkg})$, where P_{rpkg} is the common parameter of RPKG and Q_{rpkg} is the public key of RPKG. RPKG binds V to PKG by a safe method (such as smartcards).

3.2.2 Entity Authorization. Entity authorization refers to that PKGs authorize entities in their domain. Entity provides its identifiable information ID_{En} to PKG which is in the same domain with the entity. PKG generates the public key $Q_{en}=(ID_{En},T)$ for the entity. PKG computes $K_{en}=G(S_{pkg},Q_{en})$,where K_{en} is the private key of the Entity and S_{pkg} is the master key of PKG. PKG generates a tuple $V=(K_{en}, P_{pkg},Q_{pkg})$, where P_{pkg} is the common parameter of PKG, and Q_{pkg} is the public key of PKG. PKG binds V to the entity .

4 Authentication Protocols

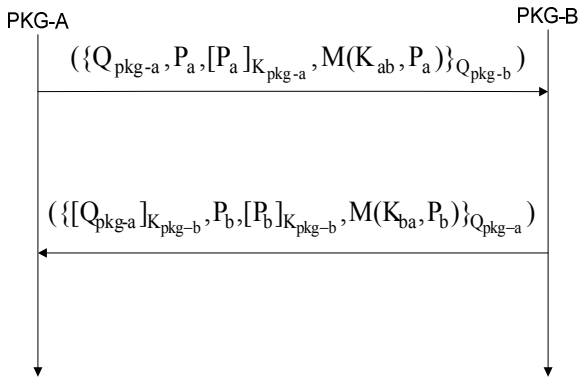

Fig. 2 Mutual authentication between PKGs

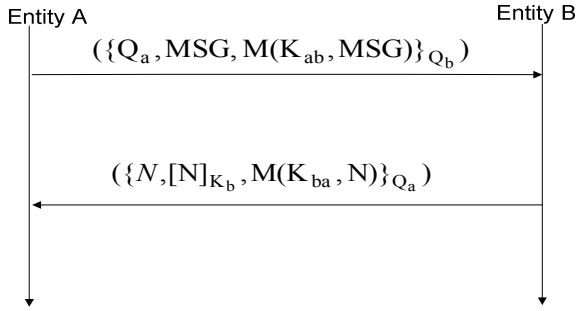

Fig. 3 Authentication between entities in the same domain

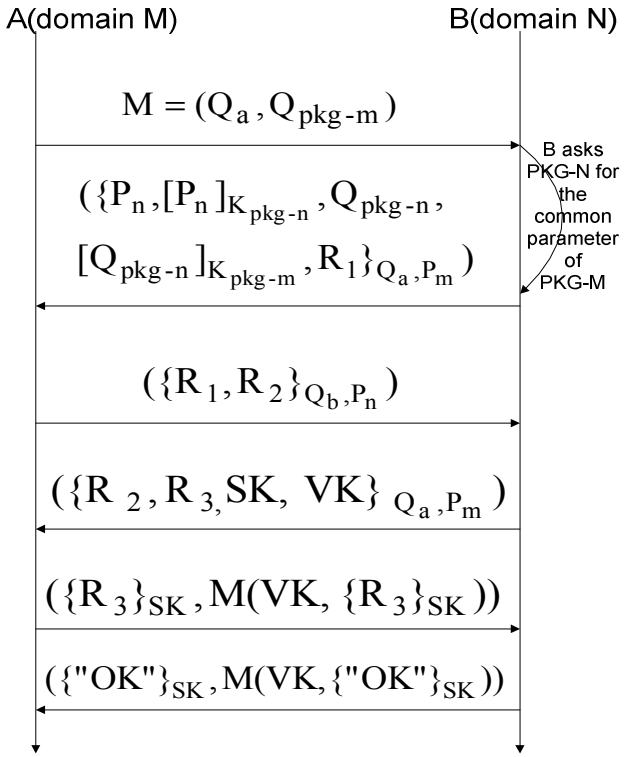

Fig. 4 Authentication between entities in different domain

4.1Authentication between PKGs. Authentications and data exchanges between entities needs the help of PKGs. So the mutual authentication between PKGs is indispensable. As shown in figure 2, a non-interactive method is used to realize the authentication and exchange the common parameters between PKGs:

Step1 PKG-A computes $K_{ab}=e(K_{pkg-a},Q_{pkg-b})$, where K_{pkg-a} is the private key of PKG-A, and Q_{pkg-b} is the public key of PKG-B. e() is the map in BF-IBE. PKG-A sends the message $(\{Q_{pkg-a},P_a,[P_a]_{K_{pkg-a}},M(K_{ab},P_a)\}_{Q_{pkg-b}})$ to PKG-B, where Q_{pkg-a} is the public key of PKG-A, and P_a is the common parameter of PKG-A. $[P_a]_{K_{pkg-a}}$ is the signatures of P_a and M() is Mac hash function. *Step2* After PKG-B receives the message, PKG-B decrypts the message and restores Q_{pkg-a}, P_a, $[P_a]_{K_{pkg-a}}$, $M(K_{ab}, P_a)$ and checks P_a by $[P_a]_{K_{pkg-a}}$, and then computes $K_{ba}=e(K_{pkg-b}, Q_{pkg-a})$, and authenticates the identity of PKG-A. The specific method is as follows: computing $M(K_{ba}, P_b)$, checking whether the result is equal to $M(K_{ab}, P_a)$. If true, the identity of PKG-A is believable. The reason is $K_{ab}=e(K_{pkg-a},Q_{pkg-b})=e(SQ_{pkg-a}, Q_{pkg-b})=e(Q_{pkg-b},SQ_{pkg-a})=e(SQ_{pkg-b}, Q_{pkg-a})=e(K_{pkg-b}, Q_{pkg-a})= K_{ba}$ [10], where S is the master key of RPKG. PKG-B signs the public key Q_{pkg-a} of

PKG-A and the common parameter of its own. Then PKG-B sends the message $(\{[Q_{pkg-a}]_{K_{pkg-b}},P_b,[P_b]_{K_{pkg-b}},M(K_{ba},P_b)\}_{Q_{pkg-a}})$ to PKG-A. After PKG-A receives the message, it decrypts it and verifies every element. After PKG-A ensures the integrity of P_b, PKG-A authenticates the identity of PKG-B using the similar method in Step3.

4.2 Authentication between entities in the same domain. The figure 3 gives the process of the authentications between the entities in the same field using the case of authentications between entity A and entity B (B can be the PKG of the domain where A is located in.). Entity A and entity B is located in the same field. Due to authentication process is similar with 4.1 and is relatively simple, it is not described in detail here, and only the parameters are explained. MSG is the request message to B sent by A. N is the reply from B, which may be the data sharing sign that contains files identifier, the public key of B, the signature of B and sharing time . N may be the session key and the verification key. $[N]_{K_b}$ is the signature of N by B.

4.3 Authentication between entities in different domain. As shown in Fig. 4, entity A belongs to domain A and entity B belongs to domain N. The authentication between A and B is described as follows:

Step1 A sends M to B, which contains the public key of A and the public key of PKG-M. PKG-M is the PKG in the domain M.

Step2 After B receives M , according to Q_{pkg-m}, B judges that he is not in the same domain with A. B uses protocol 4.2 to ask PKG-N for the common parameter of PKG-M. B sends $\left(\{Q_b, M, M(K_{bn}, M)\}_{Q_{pkg-n}}\right)$ to PKG-N. PKG-N authenticates the identity of B and restores M. According to Q_{pkg-n}, PKG-N uses the protocol 4.1 to exchange the common parameter with PKG-M. After PKG-N gets the common parameter of PKG-M, PKG-N replies $(\{N, [N]_{K_{pkg-n}}, M(K_{bn}, N)\}_{Q_b})$ to B, where $N=([P_n]_{K_{pkg-n}}, [Q_{pkg-n}]_{K_{pkg-m}}, [p_m]_{K_{pkg-n}}, P_m)$. P_n is the common parameter of PKG-N, P_m is the common parameter of PKG-M.

Step3 B decrypts the message sent by PKG-N, and checks the integrity of N, and authenticates the identity of PKG-M. Then B restores P_m and the signature of P_m,P_n and the signature of P_n, the signature $[Q_{pkg-n}]_{K_{pkg-m}}$ of Q_{pkg-n} by PKG-M. After B checks the integrity of P_m and P_n, generates the random number R_1 , and uses Q_a and P_m to encrypts $(\{P_n, [P_n]_{K_{pkg-n}}, Q_{pkg-n}, [Q_{pkg-n}]_{K_{pkg-m}}, R_1\}_{Q_a,P_m})$ and sends the result to A.

Step4 A decrypts the message, and checks the integrity of Q_{pkg-n} and P_n and then generates the random number R_2. A sends $(\{R_1,R_2\}_{Q_b,P_n})$ to B.

Step5 B decrypts the message and restores $R_1$and R_2. B compares R_1 with the one generated before to authenticates the identity of A. After that, B generates random number R_3 and the session key SK and the integrity verification key VK and then sends $(\{R_2, R_3SK, VK\}_{Q_a,P_m})$ to A.

Step6 A decrypts the message and restores R_2, R_3SK, VK. A compares R_2 with the one generated before to authenticates the identity of B. Then A encrypts R_3 with the session key SK and computes the Mac value of the encryption result with VK. A sends $(\{R_3\}_{SK}, M(VK, \{R_3\}_{SK}))$ to B.

Step7 B computes $M(VK, \{R_3\}_{SK})$,to check the integrity of $\{R_3\}_{SK}$ and restores R_3. A compares R_3 with the one generated before. If true, it proves that A receives the right SK and VK. B sends $(\{"OK"\}_{SK}, M(VK, \{"OK"\}_{SK}))$ to A to tell it the data transmission can be started.

4.4 Data Sharing. It is assumed that user A requests user B to share his data. The process is as follows:

4.4.1 A and B are in the same domain. A uses protocol 4.2 to communicate with B and gets the data sharing sign N and the signature $[N]_{K_b}$ by B. A makes use of protocol 4.2 to sends N and $[N]_{K_b}$ to the cloud server in the same domain. The cloud server checks $[N]_{K_b}$, and sends the session key SK and the integrity verification key VK to A to completes the authentication. Then the cloud server sends the data encrypted with SK to A.

4.4.2 A and B are in the different domain. A uses protocol 4.3 to communicate with B and gets the session key SK and the integrity verification key VK. Then A sends the request message to B to request the data he wants. If B agrees to share the data, B sends the data sharing sign N and the signature $[N]_{K_b}$ to A. A checks the integrity of message, and uses the protocols 4.3 to communicate with the cloud server that is in the same domain with B. A sends his public key and the public key of PKG which is in the same domain with A to the cloud server. The cloud server uses the protocol 4.2 to ask PKG-B which is in the same domain with B to get the common parameter of PKG-A which is in the same domain with A. Then the cloud server completes the mutual authentication and the exchange of the session key and the integrity verification key with A. A encrypts N and $[N]_{K_b}$ with the session key and sends it to the cloud server. After the cloud server verifies the integrity of the message and the validity of $[N]_{K_b}$, it sends the data to A.

5 Experiments and Analysis

Table 1 Platform information

Operation system	Windows7
memory	DDR3 2G
CPU	intel core i5-2400
Library	Maricl

Table 2 Encrypt and Decrypted algorithm efficiency

Block size(byte)	Encryption time(ms)	Decryption time(ms)
32	10.1	8.5
64	20.0	16.9
128	40.5	34.3
256	79.8	67.8
512	160.2	135.2
1024	319.80	269.8

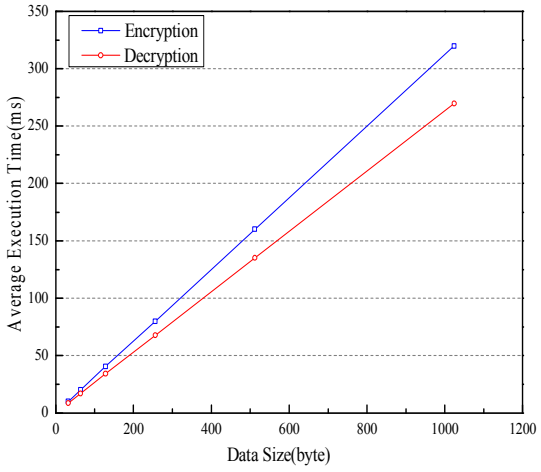

Fig. 5 Encrypt and Decrypt algorithm efficiency

5.1 BF-IBE algorithm efficiency analysis. In this study, I implements BE-IBE algorithm in [2] with chosen ciphertext security with the help of Miracl library. BF-IBE is made up of four algorithm: Setup, Extract, Encrypt, Decrypt. Since the setup algorithm is executed only once at the beginning of creating the entire system and the extract algorithm is only executed when the user registration, therefore their efficiency are not analyzed. The size of private key is 1024 bit in the experiment. The following test time does not include the pre-computation time in this experiment.

5.1.2 Encrypt and Decrypt algorithm efficiency analysis. Since the encryption and decryption of data is relatively small in the authentication process. So only the efficiency of encryption and decryption of small pieces data is analyzed.

As the test data size is in a small range and the block size to use when performing encryptions and decryptions is 32 bytes, so it can be seen the encryption and decryption time is proportional with the number of blocks from the Fig. 5 and table 2. In the authentication process, data is generally less than 1KB. So the encryption and decryption needs very short time within a reasonable range.

Table 3 The comparison of protocol 4.1 and protocol 4.1 in Cao [11]

	4.1	Cao 4.1
Encryption times	2	4
Signature times	3	4
Decryption times	2	4
Communication times	2	4

Table 4 The comparison of protocol 4.3 and protocol 4.3 in Cao [11]

	4.3	Cao 4.3
Encryption times	9	11
Signature times	3	4
Decryption times	9	11
Communication times	10	12

5.2 Comparing the protocols with the protocols in Cao. Since this system structure and authentication protocols are similar with those in Cao [11], the following pages will compare the protocol 4.1 and 4.3 with Cao [11] in the aspects of traffic and calculation. Because of the data in the authentication process is small, we use the times of encryptions and decryptions and signatures to estimate the amount of calculation and use the times of communications to estimate the traffic.

From table 3 and table 4, we can see that the times of encryptions and decryptions and signatures are far less than those in Cao. In the aspect of traffic, the times of communications are less than those in Cao.

In conclusion, the efficiency of the protocols in this paper is better than that in Cao [11].

6 Summary

This paper proposes a layered security architecture based on the thought of Cao [11] and designs three IBC-based mutual authentication protocols based on the layered security architecture. Besides, this paper provides a data sharing method based on the three protocols, which overcomes the defects in the range of data sharing in Kang [10]. The protocol 4.3 is complicated and the security of PKGs is the key of system security. So the future work is to simplify the protocol and research the problem how to protect the security of PKGs

Keywords: Fracture; *J*-Integral; computation; Stress intensity factors.

Abstract: Computation of a path independent contour integration but it yields directly the independent values of the opening mode and shear mode stress intensity factors. The calculations are not sensitive to the choice of contour. To the J-integral calculation, the present scheme calculates separately the factors K_{I} and K_{II}. A simple method to determine the SIFs for the three-dimensional crack is proposed based on the conservation integral.

Introduction

In liner fracture mechanics many different approaches to the computation of critical parameters associated with crack extension have been proposed, Among this method Rice's J-integral is extremely attractive since it involves only the evaluation of a path independent contour integral[1][2], the data for which are available from a numerical solution of the boundary value problem without any special treatment of the region surrounding the crack tip. In the application of fracture mechanics, we often encountered three dimensional configurations under complex loading.

The present paper aims at computation of a path independent contour integration but it yields directly the independent values of the opening mode and shear mode stress intensity factors. Base on finite element soft ware to formulation of crack evolution and the principal direction of crack propagation under combined tension-tear loading. The principal direction of crack propagation and associated critical energy release rate are determined.

Three dimensional J- integral for mixed model I and Ⅱ

We consider a representative cracked slice of an elastic solid having a Poisson's ratio μ, and elastic model E. For our derivation we introduce our primary local coordinate system x at an arbitrary position, rectangular Cartesian coordinates x_1, x_2, x_3, $x_1$normal to the crack front, $x_2$normal to the crack plane, $x_3$tangent to the crack front. Where portion s of the boundary is traction-free, and external loading is imposed only by traction on S. Without changing the boundary condition on S, impose a continuously varying sequence of static solution, related to the displacement u, details of the procedure can be found in references.

The countour Γ runs from the lower crack to the upper crack, the region enclosed by Γ is donated by S, we supposed that the crack faces are free of traction and on the remainder of the boundary either the displacement or the traction components in the normal and tangential directions are prescribed so that we have a well posed problem. The stress and displacements in the neighbourhood of the crack tip are known[3]in reference[4]，referring to the natural polar coordinate system indicated in Fig.1.

For the three-dimensional elastic solids, the following integrals can be given from the conservation law.

$$J_j = \int_s \left(w n_j - T_i u_{i,j} \right) \mathrm{d}s \tag{1}$$

Eq.(1) has two components, J_1 and J_2. They can all be used to calculate the stress intensity factors for the cracked elastic bodies. In the following section some key steps to calculate the SIF for the indentation have been developed based on the J-integral.

$$J_1 = \int_{\Gamma} \left(w n_1 - T_i u_{i,1} \right) ds \tag{2}$$

$$J_2 = \int_{\Gamma} \left(w n_2 - T_i u_{i,2} \right) ds \tag{3}$$

where $n_1 = cos(n,x)$; $n_2 = cos(n,y)$; $w = \frac{1}{2}\sigma_{ij}\varepsilon_{ij}$; $T_i = \sigma_{ij} n_j$.

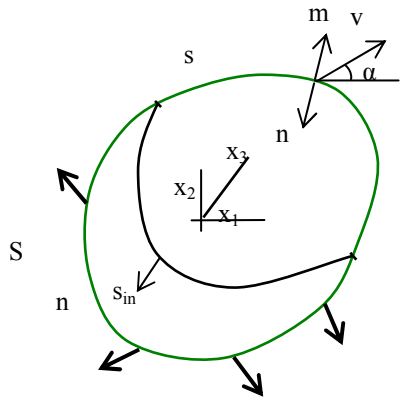

Fig.1 Three-dimensional deformation fields

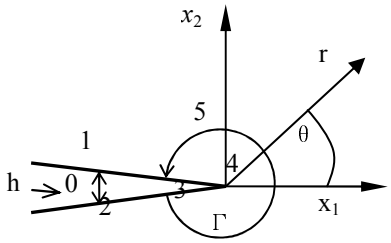

Fig.2 The integral loop for crack propagation

Substitution the stress and displacements to eq. (2) ~ (3), a routine evaluation of the integral produces

$$J_1 = \frac{\left(1-\mu^2\right)\left(K_{\mathrm{I}}^2 + K_{\mathrm{II}}^2\right)}{E} \tag{4}$$

$$J_2 = -\frac{2\left(1-\mu^2\right)K_{\mathrm{I}} K_{\mathrm{II}}}{E} \tag{5}$$

Which means that the SIF can be calculated by the J-integral, along the path from any point at the lower surface to any point at the upper surface.

Energy release rate for boundary cracking

For a homogenous and isotropic quasi-brittle substrate, the maximum energy released rate of boundary cracking can be given by

$$\frac{\partial \Pi}{\partial t} = \int_s w v_i m_i ds \tag{6}$$

Where v_i denotes the velocity of the point on s， and m_i is the current outward normal to s. Let $v_i = e_i = \Delta_i / \Delta$, which corresponds to two components of unit boundary shift, so that $e_1 = \cos\alpha$, $e_2 = \sin\alpha$, where α is the angle between shift Δ and x_1 and represents the direction of the boundary shift, β is the angle between shift Δ and x_2. Let $n_i = -m_i$ be the unit inward normal on boundary s, which means that the boundary s moves inward[5] [6], e.g. the case of crack growth. Thus, the energy release rate of boundary shift is given by

$$G = \frac{\partial \Pi}{\partial t} = \int_s w e_i n_i ds \tag{7}$$

Combine this conservation law J_i, proposed by Eshelby. The energy release rate expressed by Eq(6) can then be rearranged along the *v*-direction, with the limit $s \to 0$ the energy release rate of boundary cracking can be defined as

$$\overline{G} = J_i e_i = J_1 \cos\alpha + J_2 \sin\alpha \tag{8}$$

Where $J_1\big|_{s\to 0}$ denotes the driving force of boundary cracking in direction x_1, $J_2\big|_{s\to 0}$ denotes the driving force of boundary cracking in direction x_2, when the limits taken exist. Substitution (4) and (5) to equation (8), the following result can be found:

$$G = \frac{(1-\mu^2)K_{\mathrm{I}}^2}{E}\sqrt{f^4+6f^2+1}\cos(\alpha-\beta) \tag{9}$$

where $\beta = arctan\dfrac{-2f}{1+f^2}$, f equal $K_{\mathrm{II}}/K_{\mathrm{I}}$, The maximum energy release rate is now maximised with respect to $\dfrac{dG}{d\alpha}=0$. By setting $\sin(\alpha_c-\beta)=0$, which given the crack angle:

$$\alpha_{\mathrm{c}} = \arctan\frac{-2f}{1+f^2} \tag{10}$$

Where α_c is the theoretical expected angles and possible cracking angles at which maximum G value, and explicitly this is given by

$$G_{\max} = \frac{(1-\mu^2)K_I^2}{E}\sqrt{f^4+6f^2+1} \tag{11}$$

For a homogenous and isotropic brittle solid Griffith's criterion states that a crack will propagate when the critical value G_c of the solid is equal to the driving or applied G_{max}

$$G_{max} = G_c \tag{12}$$

Some discussions

Here we build a three dimensional crack configuration with a known exact solution so as to be able to evaluate the capability of our J integral to extract stress intensity factors. In this first test problem，the single edge crack subjected to a uniform tension, the second problem is a cantilever subject to end shear and has the same geometry as the first. We calculate three-dimensional J-integral on each of the test problem.

For the mode Ⅰ crack, traditional integral loop is shown in Fig.2． In this case we have

$$J_1\big|_{s_{231}\to 0} = \lim_{S241\to 0}\int_{S_{241}}(wn_1 - T_i u_{i,1})\mathrm{d}s = \frac{(1-\mu^2)K_{\mathrm{I}}^2}{E} \tag{13}$$

$$J_2\big|_{s_{231}\to 0} = \lim_{S241\to 0}\int_{S_{241}}(wn_2 - T_i u_{i,2})\mathrm{d}s = 0 \tag{14}$$

Then , the equation (7) becomes:

$$G = \frac{(1-\mu^2)K_{\mathrm{I}}^2}{E}\cos\alpha \tag{15}$$

It is clear the maximum energy release rate for crack extension is given by

$$G_{\max} = \frac{(1-\mu^2)K_{\mathrm{I}}^2}{E} \tag{16}$$

It represent the energy-based driving force for mode I crack, Fig.3 shown a typical image of crack branching which have been derived by Xie Y J (2010).

For the mode Ⅱ crack, the integral loop same with mode Ⅰ , in this case we have

$$J_1\big|_{s231\to 0} = \lim_{S241\to 0}\int_{S241}(wn_1 - T_i u_{i,1})\mathrm{d}s = \frac{(1-\mu^2)K_{\mathrm{II}}^2}{E} \tag{17}$$

$$J_2\big|_{s231\to 0} = \lim_{S241\to 0}\int_{S241}(wn_2 - T_i u_{i,2})\mathrm{d}s = 0 \tag{18}$$

Then, the equation (7) becomes

$$G = \frac{(1-\mu^2)K_{II}^2}{E}\cos\alpha \tag{19}$$

so maximum energy release rate for crack extension is given by

$$G_{\max} = \frac{(1-\mu^2)K_{II}^2}{E} \tag{20}$$

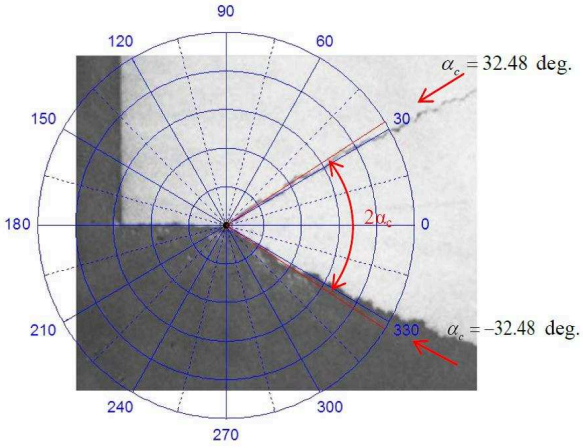

Fig.3 A typical image of crack branching mode I crack

Conclusions

The integral reported here is an accurate, reliable for the calculation of the intensity of singular stress distribution in plane, isotropic elastic material problems. The calculations are not sensitive to the choice of contour. An energy-based fracture model for mixed mode has been developed and formulized. Unlike the traditional applications of the J-integral around a crack-tip, a new partial integral path and the associated calculation method for the energy release rate had been defined. Both the cracking angle and the critical energy release rate of mixed crack have been proposed.

A Kind of MSD Performance Compensation Method Based on the Strategy of Sliding

Zhu Dongxu[1,a] , Fu Gang[1, a], and He Qian[1,a]

[1]China Satellite Maritime Tracking and Control Department, China

[a]348237548@sina.com

Keywords: Sliding strategy, PCM/FM, MSD

Abstract. The signal noise ratio (SNR) of telemetry signals is low in the environment of reentry telemetry, MSD(Multi-Symbol Detection) technology can effectively improve PCM/FM telemetry signal demodulation performance. In view of the problem that maximum likelihood value is misjudged leaded by the noise in the process of reentry and doppler causing serious distortion of signal phase. A performance compensation method of MSD based on sliding strategy is researched: A MSD operation with N-1 element overlap before each MSD operation, where the each symbol sliding strategy sliding the length of 1 symbol. The simulation and test results verify the effectiveness of the improved algorithm.

Introduction

The PCM/FM system is widely used in missile and aircraft telemetry, mainly applied to the target spacecraft reentry telemetry. Goal is through the blackout area, the attitude of the track changes and tumbling frequency big influence on SNR of telemetry signals, so its under low signal-to-noise ratio of remote sensing signal demodulation is the main research problems. And symbol detection technology can effectively improve performance of PCM/FM signal demodulation, channel gain can be increased nearly 3 dB[1][2], which can effectively solve the traditional demodulation threshold for PCM/FM signal demodulation. Because the MSD is based on phase correlation arithmetic, so in the telemetry signal phase affected by noise and doppler serious cases, it is easy to cause MSD maximum likelihood of misjudgment, affect the demodulation performance.

To reduce the probability of maximum likelihood was wrongfully convicted in MSD, further improve the performance of telemetry signal demodulation, this paper puts forward a kind of MSD performance compensation method based on sliding strategy, this strategy can to a certain extent, reduce the probability of maximum likelihood value is misjudgment, with traditional MSD and the complexity of algorithm.

1 Traditional algorithms of MSD

Assumption is *z* sends a sequence of binary information symbols. And symbol detection method, namely by finding an optimal sequence of judgment, also is in determining the received signal under the condition of the *r(t)*, sequence $\bar{z}$ have the greatest probability. According to bayes theorem:

$$p(\bar{z}/r(t)) = \frac{p(r(t)/\bar{z})p(\bar{z})}{p(r(t))} \tag{1}$$

To facilitate the derivation, using the logarithmic notation $\ln(p(r(t)/\bar{z}))$, noise as gaussian white noise, the *r(t)* with mean $s(t;z)$. T for the element width, when the *n(t)* is generalized stationary random process, the $\ln(p(r(t)/\bar{z}))$ is equivalent to the largest to maximize the $-\int_0^{NT}(r(t)-s(t;\bar{z}))^2dt$, which is equivalent to minimize the $\int_0^{NT}(r(t)-s(t;\bar{z}))^2dt$, namely the minimum Euclidean distance, said as follows:

$$\max\{\ln(p(r(t)/\bar{z}))\} \Leftrightarrow \min\left\{\int_0^{NT}(r(t)-s(t;\bar{z}))^2dt\right\} \tag{2}$$

Within the N element, define the minimum Euclidean distance to *r(t)* as follows:

$$r_{\min} = \min\left\{\int_0^{NT}(r(t)-s(t;\bar{z}))^2 dt\right\}$$
$$= \min\left\{\int_0^{NT} r^2(t)dt + \int_0^{NT} s^2(t;\bar{z})dt - 2\int_0^{NT} r(t)s(t;\bar{z})dt\right\} \quad (3)$$

$$T(\bar{z}) = \int_0^{NT} r(t)s(t;\bar{z})dt \quad (4)$$

Because of the noise and are independent of symbols, $\int_0^{NT} r^2(t)dt$ and $\int_0^{NT} s^2(t;\bar{z})dt$ as constant value, therefore, the minimum Euclidean distance equivalent to the maximum correlation $T_{\max}$, namely:

$$T_{\max}(\bar{z}) = \max\left\{\int_0^{NT} r(t)s(t;\bar{z})dt\right\} \quad (5)$$

The formula (5) into a recursive form:

$$T_n(\bar{z}) = T_{n-1}(\bar{z}) + \lambda_n(\bar{z}) \quad (6)$$
$$\lambda_n(\bar{z}) = \int_{(n-1)T}^{nT} r(t)s(t;\bar{z})dt$$

$T_n(\bar{z})$ for n element of likelihood function, called measurement, $T_{n-1}(\bar{z})$ said before n-1 symbol of the likelihood function, $\lambda_n(\bar{z})$ as distance increment, said signal in $nT \le t \le (n+1)T$ time likelihood value of additional measures. Because before each measurement is a measurement with the current element cycle cumulative likelihood value, search a $\bar{z}_i$, namely that:

$$T_n(\bar{z}_i) \ge T_n(\bar{z}_j) \quad i \ne j$$

Through the above analysis we can see that in a certain period of time within (*NT)*, namely N element, for the duration of the best decision is the most close to find a *r(t)* and receiving signal modulation signal of $s(t;\bar{z})$. Thus, calculate the likelihood function of $p(r(t)/\bar{z})$ maximum converted to obtain the maximum of $|T(\bar{z})|$ problems. MSD is looking for the corresponding sequence, has the absolute value of $|T(\bar{z})|$ maximum likelihood.

Obtain type (6) likelihood value of the specific process as shown in figure 2.

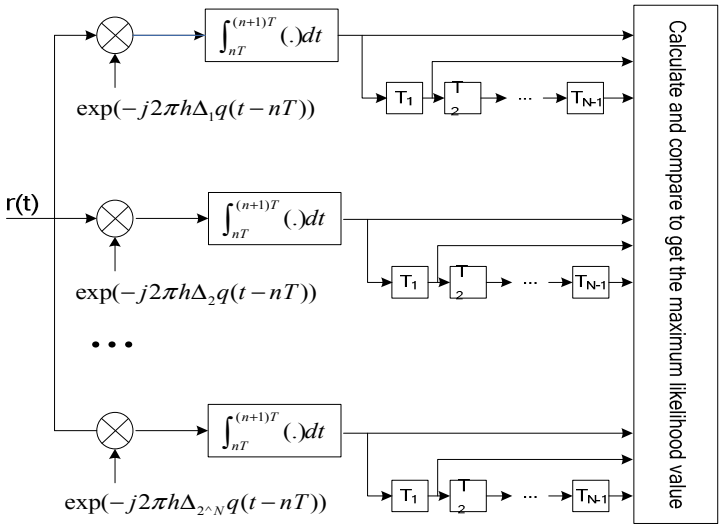

Fig1 Multiple symbol detection algorithm implementation block diagram

Among them, the likelihood calculation is as follows:

$$\beta_i = \sum_{n=1}^{N} \Gamma_{i_{n,N-n}} C_n \quad , \quad C_1 = 1 \quad , \quad C_k = \exp(-j\pi h \sum_{l=1}^{k-1} \Delta_{i_l})$$
$$\hat{a}_{n-N+1} = \Delta_{i_1} \quad \hat{a}_{n-N+2} = \Delta_{i_2} \quad \ldots \quad \hat{a}_n = \Delta_{iN}$$

Observation length N off for 5 of this article, the corresponding local code is $2^N = 32$ groups, to send information in the simulation code for 1 [1-1-1-1-1], using MSD likelihood value relationship with the block sequence and time shift is shown in figure 2:

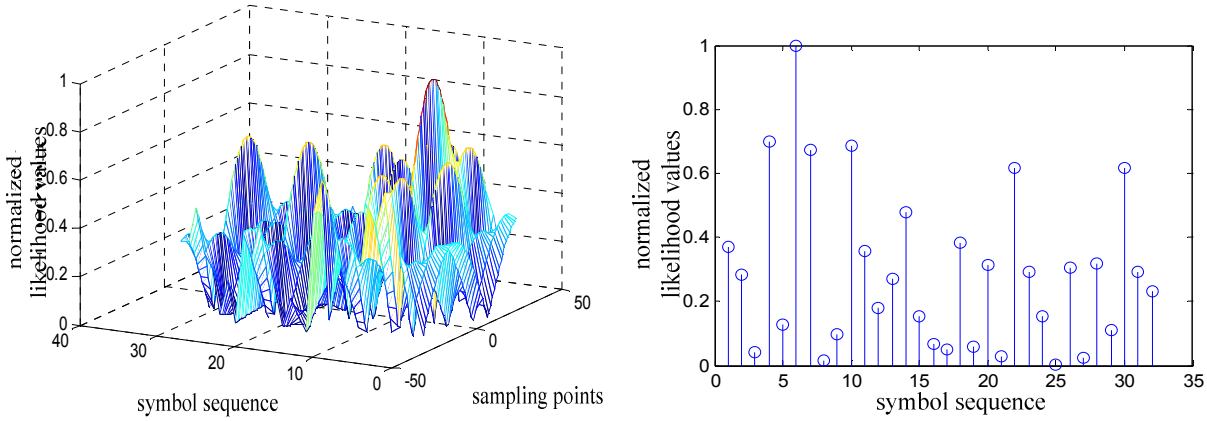

Fig. 2 Relations between likelihood value, delay interval and block sequence

2 MSD performance compensation

By simulation it can be seen that before after MSD operation, some channel likelihood value, compared with maximum likelihood likelihood value size close to, can see clearly that higher likelihood peak of around 0.7, to has a great influence on the decisions of the main peak, namely in the noise and under the influence of time delay and doppler, it is easy to cause the results of MSD miscalculation.

Listed above the graph example, the peak time corresponding block as shown in table 1.

Table 1 Code corresponding to the likelihood value

Block number	6	4	7	10
symbol sequence	1 -1 1 -1 -1	1 1 -1 -1 -1	-1 1 1 -1 -1	1 -1 -1 1 -1
Likelihood value	max	next	next	next

Can be seen from table 1, when the symbol sequence is similar, likelihood value comparison, the probability of mistakes that is bigger, so you need to study a kind of strategy can reduce the misjudgment rate of symbol sequence changes. A sliding strategy under study, that is, every time sliding element 1 time sliding strategy, and the corresponding sliding conditions were analyzed.

Looking for maximum likelihood in MSD values corresponding to the local block in the process, when a group of element demodulation is determined, the relationship between the adjacent block should be considered. Sliding along the time axis, a sliding one element at a time, every time the interception of five element length calculation, specific sliding condition as shown in figure 3.

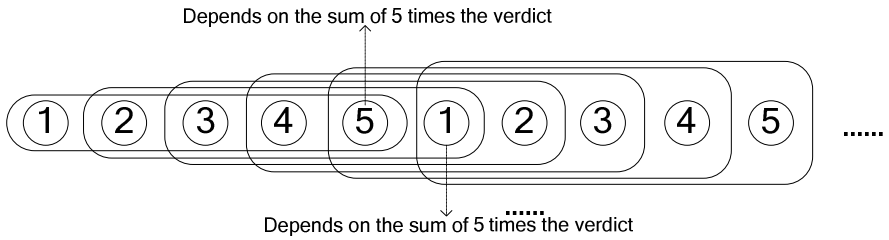

Fig3 Time sliding strategy map (sliding one code)

From figure 1, you can see, from the symbol sequence of the third element, after each element was found at least twice, because the decision for many times, so the formation of the sliding strategy for correction caused by excessive noise, so as to effectively reduce the error rate.

3 Algorithm performance.

Figure 4 is under gaussian noise, without sliding strategy and through a sliding element of MSD.

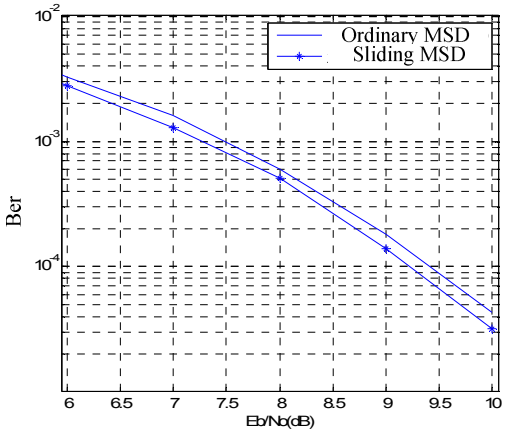

Fig4 BER contrast diagram of sliding strategy

Can be seen from above, MSD algorithm adopts sliding, after a time element sliding strategy in ber to 10^{-4}, SNR gain 0.3dB, demodulation performance obtained certain to improve.

Summary

Symbol detection method is based on the idea of maximum likelihood, of continuous several codes signal joint detection, and by comparing with the local signal integration have been the likelihood value size to achieve signal demodulation. Traditional sliding length is the length N, and when using sliding length is one element of strategy, according to the simulation signal telemetry standards manual, under a certain noise intensity, the sliding strategy before and after the MSD demodulation method is adopted to improve the bit error rate test. Test results show that the sliding one element of the strategy after demodulation error rate performance obtained certain to improve.

Keywords: Signal Processing, Phase Locked Loop, Partitioning strategy

Abstract. Signal processing speed is an important indicator of the performance of software based phase-locked loop. Previous software uses data redundancy of phase-locked loop based on parallel processing, but the amount of redundant data lead to the introduction of computer waste of resources, reducing efficiency and other issues. Design of a parallel processing method based on data blocks and redundant data segments dual dynamic partitioning, given the dynamic data partitioning strategy.

Introduction

PLL is a common method of signal processing. With the advent of digital signal processing by means of software, "pure software" of the real-time processing, this method is called virtual radio[1]. To the parallel processing method can improve the operation speed. Literature for the parallel processing method based on a phase locked loop data redundancy, the method preferably achieved at the same time parallel processing of a plurality of software PLL. But will lead to a waste of computer resources, reduced efficiency and other issues. To this end, this paper studies the dynamic partitioning of the data segment parallel processing.

1 Data redundancy based on phase-locked loop parallelization and its problems

How to convert an analog system to the same function, similar to the performance of digital systems become critical software PLL design. Functionality and performance of a system can be determined by its transfer function, the transfer function corresponding to the simulation system S domain, the transfer function corresponding to the digital system Z domain. Z-domain transfer function of the system will convert the time domain in the form of differential equations, mathematical model of software as a phase-locked loop. Second-order phase-locked loop Z-domain model ideal integrator filter shown in Figure 1.

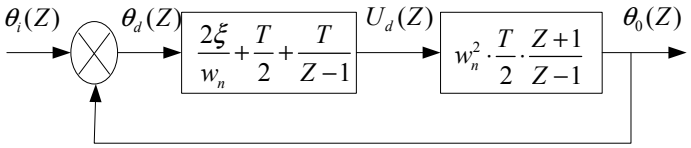

Fig1 SPLL Z domain model

As can be seen from the figure, the impact of the performance parameters of the phase locked loop is only natural resonant frequency and damping[2]. Digital phase locked loop parameters can be selected with reference to the method for setting the parameters.

2 Based on the description of the method of parallel data redundancy

Approach is to use the software PLL data A/D samples obtained according to a fixed length, which is the use of the serial data, the input data block to be processed. If the data block segmentation parallel processing, there is the parallel processing of each of the tracking loop process a data block is not locked, the tracking results in a larger error of the data gaps, as shown in Figure 2.

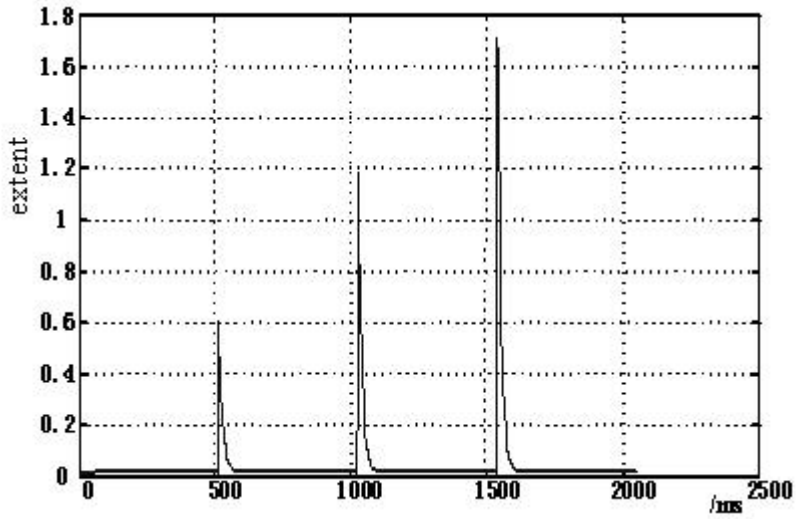

Fig2 Non-redundant parallel track results

For job tracking loop characteristics, the parallel data on the basis of data redundancy information loss problem solving unlocked state. The basic principle shown in Figure 3.

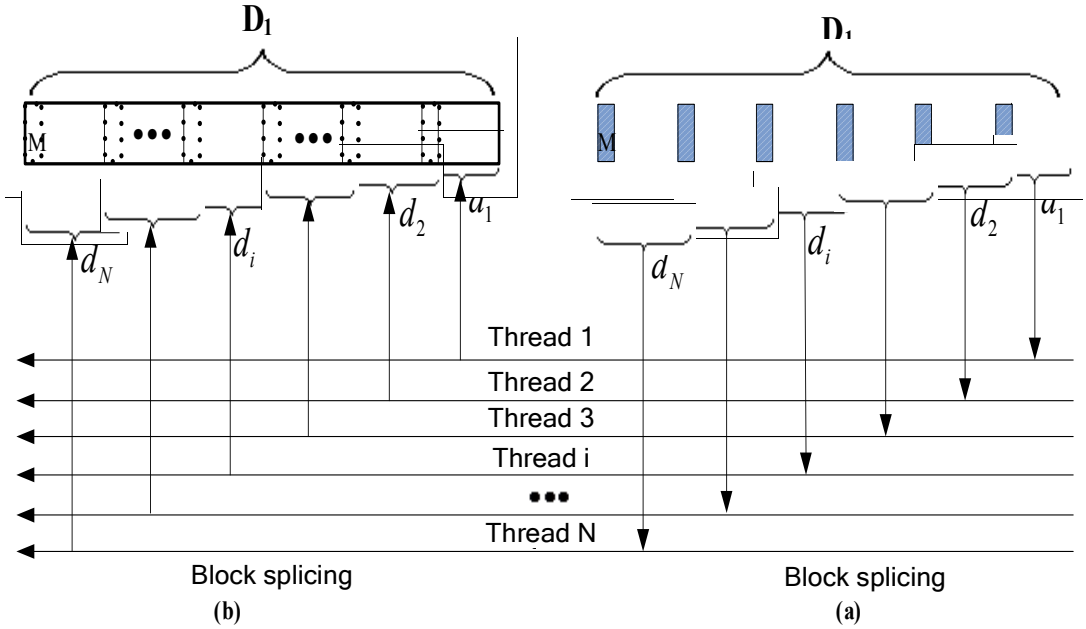

Fig3 Based on data parallelism to achieve redundancy software PLL schematics

3 Dynamic partitioning of data blocks

Earlier analysis of parallel loop uses a fixed block of data partitioning method, the data block is the fixed division before making the tracking process using fixed-length data block is divided in chronological order.

This partitioning method is simple and easy to implement, but the signal tracking loop design to consider the loop loses lock recapture problems. If the loop loses lock occurs, you need to re-start the capture process, the received signal recapture. Process for tracing data blocks in a plurality of parallel processing subblocks, wherein any process should be carried out occurs again lock catch, the catch of the local code and the local carrier frequency phase needs to be updated.

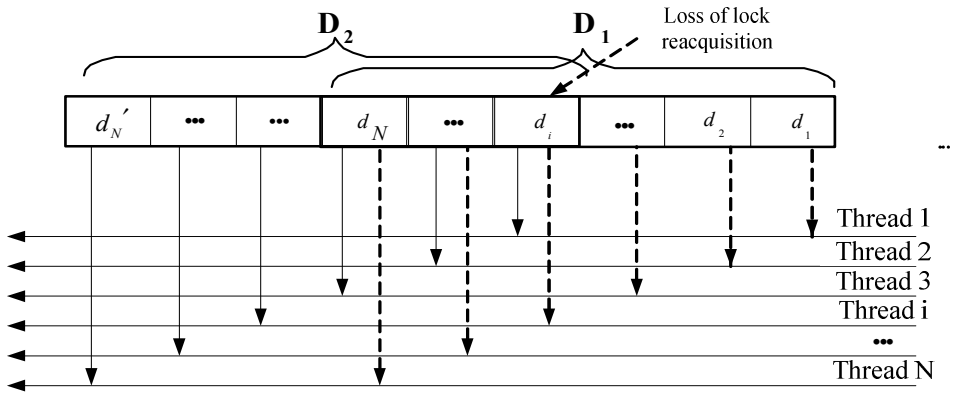

Fig4 Dynamic data partitioning method

Figure 4, the tracking process is not before the division of the data stream according to the time length of the sequence, etc., the start and end of the data segment is not fixed. The first data block is divided into N sub-blocks. If the parallel process does not appear out of lock, the next block of data from the beginning of the end position of division, and the same fixed data block division method.

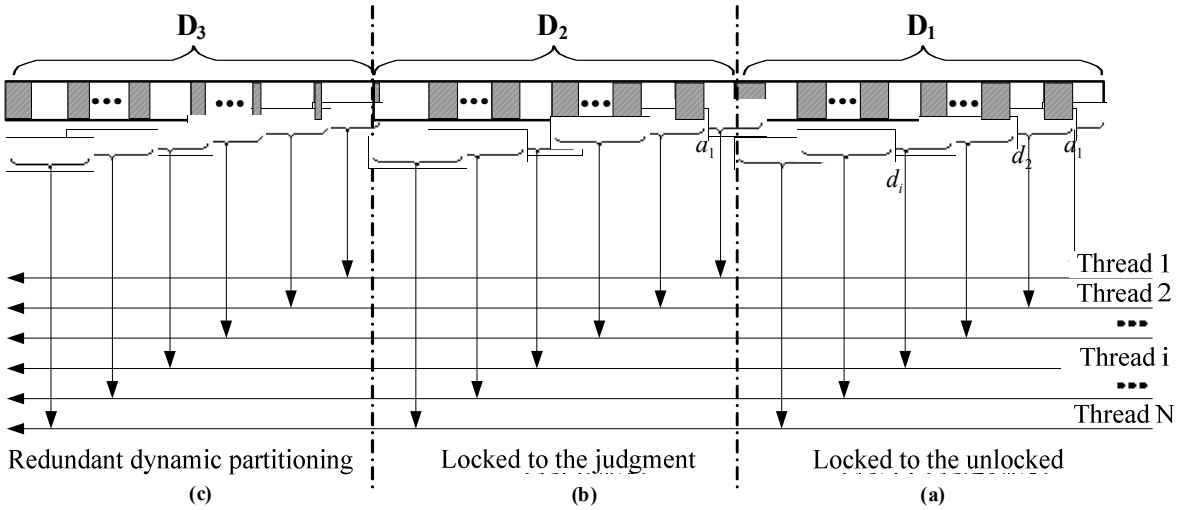

Fig5 Schematic dynamic partitioning redundant data segments

As can be seen from the figure, the dynamic partitioning method, redundant data segments is shortened, the redundant data segments to effectively avoid the waste of resources caused by the fixed dividing process and improve the efficiency of the parallel.

4 Parallel simulation and analysis of polycyclic

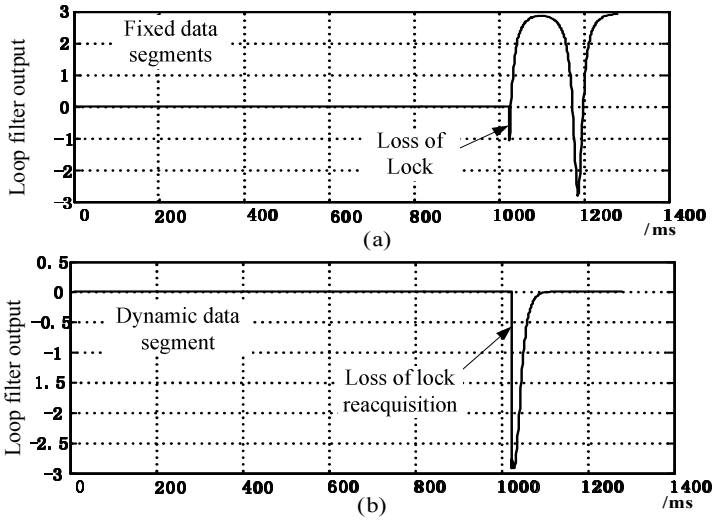

Fig6 Comparison of the data segment division method...

The simulation results shown in Figure 6, parallel tracking loop loses lock the segment in Fig6 (a) is fixed on the divided data block is not tracked, and Fig6 (b) based on the dynamic data block can be divided in the tracking loop lost after the lock on the track again soon caught. Seen from the simulation results, parallel to the frequency of the carrier tracking loop ramp with a single ring signal tracking capability is roughly equal. The above simulation results show that the dynamic tracking performance of parallel phase-locked loop to meet the design requirements.

Summary

This method not only improves the signal after the loss of lock catch speed, minimize the loss of data caused by the loss of lock, and effectively reduces the amount of data redundancy to further improve the efficiency of the parallel.

An Algorithm to Control Watermarking Capacity Using PSNR

Yong Xing[1, a], Daoshun Wang[1, b]

[1]Department of Computer Science and Technology, Tsinghua University, Beijing 100084, China.

[a]xingyong163@163.com, [b]wangdaoshun@gmail.com

Key Words: Perceptual Model, Image Quality, PSNR, Watermarking Capacity.

Abstract. Some existing methods for estimating image watermarking capacity may degenerate the quality of stego-image when the estimated capacity is achieved. In this paper, based on the Region of Interest (ROI) model, we discuss on the capacity problem and the quality of stego-images using PSNR. Considering the trade-off between capacity and quality, our method estimates the allowable distortion for each pixel in spatial domain in terms of the specific PSNR of stego-image. Experimental results show our method ensures a good control over the capacity without introducing artifacts.

1 Introduction

The purpose of watermarking capacity research is to evaluate how much information can be hidden into a digital cover image while satisfying watermarking invisibility and robustness [1-2]. There are many related works for calculating watermarking capacity. Moulin et al. regarded watermarking as information channel between encoders and decoders and studied optimal watermarking strategies under constrained resources [3]. Zhang et al. used Noise Visibility Function (NVF) to compute the allowable distortion of each pixel by its neighbors' values [2]. Based on this, Yaghamee et al. defined NVF as the depth of each pixel in the quadtree decomposition of the cover image [4]. They also proposed a new method to estimate image complexity based on the concept of ROI and used ROI to calculate capacity [5]. In addition, Caciula et al. [6] and Pei et al. [7] researched the capacity of adaptive reversible watermarking.

However, these existing methods have ignored the quality issues [8]. When the number of embedded bits reaches the upper bound, the quality of stego-image becomes poor. To solve this problem, we see image quality as a parameter when calculating capacity. Then, watermarking capacity is the maximum number of bits that can be hidden in terms of particular quality requirements.

2 Background and Motivation

Zhang et al. used NVF to analyze watermarking capacity [2]. NVF is a function characterizes local image properties, identifying textured and edge regions where watermark should be more strongly embedded. The NVF at each pixel (*r, c*) is written as

$$\mathrm{NVF}(r,c) = \frac{1}{1+\delta_x^2(r,c)} \tag{2-1}$$

where $\delta_x^2(r,c)$ is the local variance in a window centered on the pixel (*r, c*). Yaghmaee et al. [4] partitioned $N \times N$ cover image and redefined NVF at each pixel (*r, c*) with its level $L(r, c)$ in the quadtree as

$$\mathrm{NVF}(r,c) = \frac{L(r,c)}{\log_2 N} \tag{2-2}$$

In both of these two methods, the allowable distortion of each pixel (*r, c*) is

$$\Delta(r,c) = \big(1 - \mathrm{NVF}(r,c)\big) \cdot \Delta_0 + \mathrm{NVF}(r,c) \cdot \Delta_1 \tag{2-3}$$

where Δ_0 and Δ_1 are the maximum allowable pixel distortions in textured and flat region respectively. All the watermark amplitudes build an image named Maximum Watermark Image (MWI).

In order to investigate the quality of stego-images when the number of embedded bits reaches the estimated capacity, we do experiment on 2180 images with Zhang's method and Yaghmaee's method respectively, and compute the PSNR's of their MWI's. The result is presented in Table 1.

Most PSNR's are no more than 22, with the Zhang's method, and are between 22 and 28, with the Yaghmaee's method. This shows that these two methods have ignored the trade-off between capacity and quality and thus over-estimated the capacity. If taking the quality of stego-image as a parameter, we can ensure the stego-image can achieve the desired quality requirements.

Table 1: Distribution of the PSNR of Stego-images

Range of PSNR	Zhang et al. [2] method		Yaghmaee et al. [4] method	
	Number	Ratio	Number	Ratio
[30, +∞)	14	0.64%	72	3.30%
[28, 30)	9	0.41%	45	2.06%
[26, 28)	22	1.01%	227	10.41%
[24, 26)	65	2.98%	721	33.07%
[22, 24)	180	8.26%	994	45.60%
[20, 22)	911	41.79%	119	5.46%
[0, 20)	979	44.91%	2	0.09%
Total	2180	100%	2180	100%

3 The Proposed Algorithm

Yaghmaee et al. proposed the ROI model to measure image complexity [5]. They divided cover image into 16 blocks, computed *Intensity*, *Contrast*, *Location*, *Edge* and *Texture* for each block, and integrated the five parameters into *Importance Measure* (IM), a real number between 0 and 1, to represent the image content. For there is direct relation between watermarking capacity and image complexity, capacity is closely associated with IM. Taking into consideration the quality of stego-image, which is usually measured by PSNR, we estimate capacity based on the ROI model.

Let $P_{expected}$ be the expected PSNR of stego-image. $P_{expected}$ is controlled by watermark encoder and expresses the expected quality of stego-image. This requires that the actual PSNR of stego-image should no less than $P_{expected}$. We propose an algorithm to calculate the capacity of a gray-level image as following.

Algorithm: Computing the capacity of cover image

Input: A cover image S and the expected PSNR $P_{expected}$ of its stego-image S'

Output: Capacity C of the cover image

Steps:

1. Based on the ROI model [5], divide the cover image S into blocks and calculate $\mathrm{IM}(S_i)$ for each block S_i.
2. Obtain the assumed PSNR of each block S_i in stego-image by computing
$$P_i = \frac{P_{expected}}{[\mathrm{IM}(S_i)]^{1/(2N_b)}} \quad (3\text{-}1)$$
where N_b is the number of blocks. In the ROI model, $N_b = 16$.
3. Estimate the maximum distortions of the pixels in block S_i as
$$\Delta_i = \frac{255}{\sqrt{t_i}} \quad (3\text{-}2)$$
where $t_i = 10^{P_i/10}$ is a parameter dictated by P_i.
4. Let $\delta_x^2(r,c)$ be the local variance of block S_i in the 3×3 window centered on the pixel (r, c).The tolerable distortion of pixel (r, c) is
$$\Delta(r,c) = \left(1 - \frac{1}{\sqrt{1+\delta_x^2(r,c)}}\right) \cdot \Delta_i \quad (3\text{-}3)$$
5. All pixel distortions make a new image named MWI. Assume σ_{iw}^2 denotes the variance of the corresponding MWI block and σ_n^2 denotes the variance of noise. The watermarking capacity of the whole cover image is

$$C = \sum_i C_i = \sum_i W_i \log\left(1 + \frac{\sigma_{iw}^2}{\sigma_n^2}\right) \quad (3\text{-}4)$$

There are some explanations essential for us to understanding this algorithm. First, a larger $\mathrm{IM}(S_i)$ means more distortion in S_i is acceptable. Second, if we partition the cover image into substantially uniform blocks of different sizes by quadtree decomposition [4], the number of blocks is usually more than 16 and all allowable distortions of the pixels in block S_i are approximately the same as (3-2). Third, as NVF does in [2], the different textures around different pixels result in different tolerable distortions. (3-3) indicates richer texture can tolerate more distortions. Fourth, watermarking can be considered as a form of communication [3]. So watermarking capacity problem can be solved using traditional information theory [2]. We treat the whole image block S_i as one AWGN channel and assume every block suffers from the same channel attack. Then the capacity of the whole image is the sum of those for each block in (3-4).

4 Analysis on Stego-image Quality

We analyze the quality of stego-image when the number of embedded bits reaches the estimated capacity. Let P_{actual} be the actual PSNR of stego-image. According to the definition of PSNR,

$$P_{actual} = 10 \cdot \log_{10} \frac{m \cdot n \cdot 255^2}{\sum_{r,c}(S'(r,c) - S(r,c))^2} \quad (4\text{-}1)$$

Considering $\Delta(r,c) = S'(r,c) - S(r,c)$, according to (3-2) and (3-3),

$$P_{actual} = 10 \cdot \log_{10} \frac{m \cdot n}{\sum_{r,c}\left[\left(1 - \frac{1}{\sqrt{1+\delta_x^2(r,c)}}\right)^2 \cdot \frac{1}{10^{P_i/10}}\right]} \quad (4\text{-}2)$$

Let $\mathrm{IM}_{max} = \max_i\{\mathrm{IM}(S_i)\}$. Applying (3-1) to (4-2), we get

$$P_{actual} \geq 10 \cdot \log_{10} \frac{m \cdot n \cdot 10^{P_{min}/10}}{\sum_{r,c}\left[\left(1 - \frac{1}{\sqrt{1+\delta_x^2(r,c)}}\right)^2\right]} \quad (4\text{-}3)$$

Obviously, $1 - \frac{1}{\sqrt{1+\delta_x^2(r,c)}} < 1$. Then

$$P_{actual} > 10 \cdot \log_{10} 10^{\frac{P_{min}}{10}} = P_{min} = \frac{P_{expected}}{(\mathrm{IM}_{max})^{1/(2N_b)}} \quad (4\text{-}4)$$

Because of $\mathrm{IM}(S_i) \in (0,1)$, we have $\mathrm{IM}_{max} < 1$ and $(\mathrm{IM}_{max})^{1/(2N_b)} < 1$. Thus

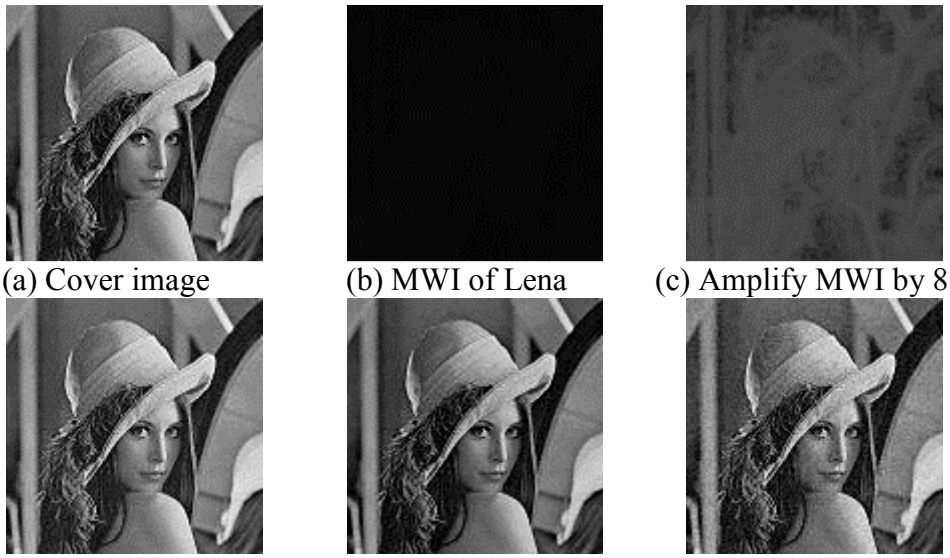
$$P_{actual} > P_{expected} \quad (4\text{-}5)$$

It indicates that stego-image S' can satisfy the quality requirements. But this does not means stego-images always have good quality when the number of hiding bits is below the upper bound of formula (3-4). A sufficient condition for good quality is that the modification of each pixel in cover images should not exceed its corresponding gray level of MWI. If the distortions of some regions go beyond the limit, although formula (4-4) is satisfied, the quality of stego-images may be poor. However, for our method is somewhat conservative in computing capacity, stego-images may be still good in vision even if the actual embedding capacity slightly exceeds formula (3-4).

5 Experiments

The quality of an image is generally considered to be good when its PSNR is no less than 28. So we set the expected PSNR is 28 and compute the distortions of the MWI's of 2180 cover images obtained by the proposed method in Section 3. The experimental result shows that 90.09% PSNR's are between 28 and 30, and the rest are more than 30. Take Lena image for example. Fig. 1 is the MWI and stego-images of Lena. The MWI showed in Fig. 1(b) is almost pure black because of its low gray values. Fig. 1(c) amplifies its gray values by 8 times and clearly displays the contour of Lena. This shows that our algorithm has good adaptability. Fig. 1 (d)~(f) display three stego-images obtained by three different embedding methods. These stego-images have no visual difference from

the cover image (Fig. 1(a)). Reviewing Table 1 in Section 2, we can see that the proposed algorithm can guarantee the quality of stego-images to be good.



(a) Cover image (b) MWI of Lena (c) Amplify MWI by 8

(d) Additive embedding (e) Subtractive embedding (f) Random embedding

Fig. 1: MWI and stego-images of Lena (PSNR=28.70)

In Fig. 2, we draw the curve of watermarking capacities of four experimental images. With the increase of PSNR, the quality requirements become higher, thus less modification on cover images reduces embedding capacity. When PSNR is more than 40, cover images are almost not modifiable and watermarking capacity tends to 0. In terms of any specific PSNR, the relationship of the capacities of different images is determined. It indicates that watermarking capacity depends on the self-characteristics of cover images.

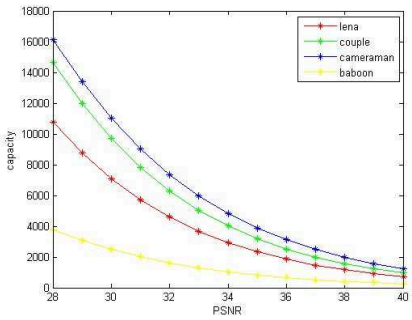


Fig. 2: Curve of watermarking capacity

6 Conclusions

In this paper, we regard image quality as one parameter and research the watermarking capacity problem closely associated with quality issues. Based on the ROI model, our method estimates the allowable distortion, the potential for embedding watermark, for each pixel in spatial domain in terms of the specific PSNR of stego-image. Experimental results show that our method can meet the quality requirements without introducing artifacts.

Simulation of Dynamic Compaction on Soft Soil Foundation

Pang Yiling [1, a], Dai Duanming [1]

[1] Department of Civil Engineering, Guangxi Polytechnic of Construction, Nanning , 530003,China;

[a]1377997225@qq.com.

Keywords: dynamic consolidation; soft soil foundation; FEM.

Abstract. Aiming at soft soil foundation, this paper simulates the process of dynamic compaction on soft soil foundation by ABAQUS, and analyzes soil stress and displacement under the effect of same tamping energy on different drop height, ram. The law of consolidation on the soil foundation has been forecasted more accurately, which is more valuable for the similar project on dynamic compaction on soft soil foundation.

1 Introduction

The soft soil foundation is very general in China's coastal areas. With the reform and opening up, and the rapid development of the economic construction in coastal areas, it has great meaning in the study of the character of soft soil foundation and its treatment method [1]. The dynamic consolidation method is also called dynamic compacting method, which drops the 100～400KN weighty hammer (the maximum is up to 2000KN) with 6-40m drop distance [2] .

Although the dynamic consolidation method is used widely in treatment of soft foundation， the theory and design method is not perfect and mature. This paper analyzes the process of the treatment of soft soil foundation in dynamic consolidation method with different construction parameters by finite element software and chooses the proper parameters based on the simulation effect.

2 Model building

2.1 Element Type and Load. ABAQUS can better simulate the mechanical response of soil under the enormous impact loads. According to the simulation of stress propagation, first-order unit is better than the second-order unit[3].So this paper chose an 8-node linear brick, reduced integration, hourglass control(C3D8R).

Wu Ming-Ping et al [4] and Lee Ping [5] simplified transient impact load to triangular pulse during the tamping process, and the calculation results were consistent with the measured data. Based on the data obtained from practices of dynamic compaction [6], when the heavy hammer ramming the ground, the acting time is generally 0.04~0.2s. In this paper, we choose 0.09s as the acting time, so the dynamic compaction loading forms are shown in Fig.1.

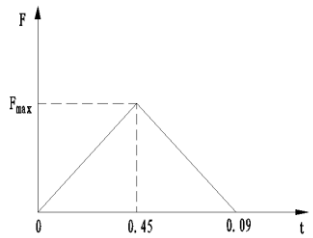

Fig.1 Dynamic Compaction Loading Forms

The hammer is placed in close proximity to the location of foundation (the hammer in this model is placed in 0.01m), and given a initial velocity in order to save the simulation time of free fall in ABAQUS/Explicit.

3 Example Analysis

3.1calculation parameters. The test site lies in the terrace of the Yangtze River. Its stratigraphical time is Q4, formed by the fluviation. The upper part is deep saturation, and lower part is sand bed. The soil layers are reduced to one in the model, because the depth of dynamic consolidation is limited. The main simulated parameter is shown in Table 1.

Table 1. The main simulated parameter

Elastic Modulus E (Mpa)	Poisson Ratio μ	Cohesion C (kpa)	Friction Angle φ (°)	Density ρ g/cm3	Flow Stress Ratio K
8.6	0.35	27	5	1.8	0.94

3.2Model Building. In the simulation model, different construction parameters have different reinforcement effect. Therefore, this paper would analyze the model in different drop height. The first combination is 28t×10m and 12t×24m(hammer weight×drop height)，Thereinto the temping energy in both of the combination is 2800KN•m.

Boundary conditions were more important to simulation, so the boundary conditions in this paper are in the following list:

- Assume that the soil type is elastic-plastic semi-infinite space which is homogeneous and isotropy;
- Take no account of underground water
- Assume that the hammer is rigid body
- Take no account of energy loss in the impact process.

It is important for numerical simulation. Finite element mesh generation is one of critical techniques for FEM. The mesh generation in this model is plotted in Fig.2

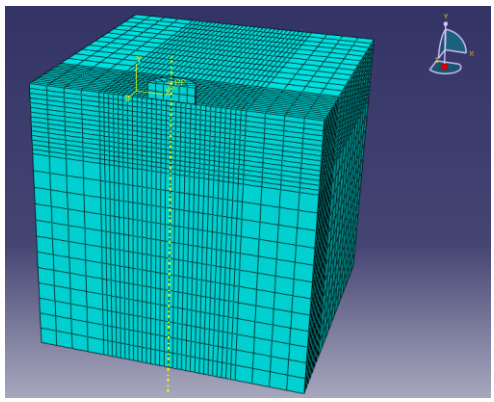

Fig.2 Mesh generation

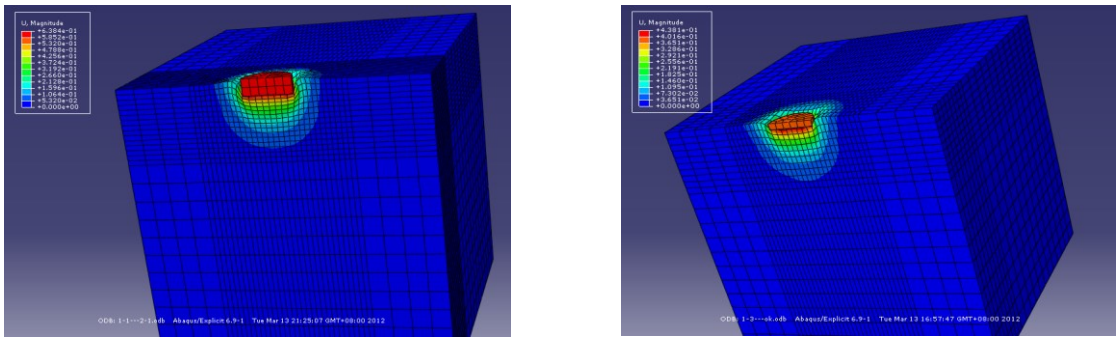
4 The simulation results and analysis of different hammer weight and drop height under the action

4.1 Vertical Displacement Distribution Map



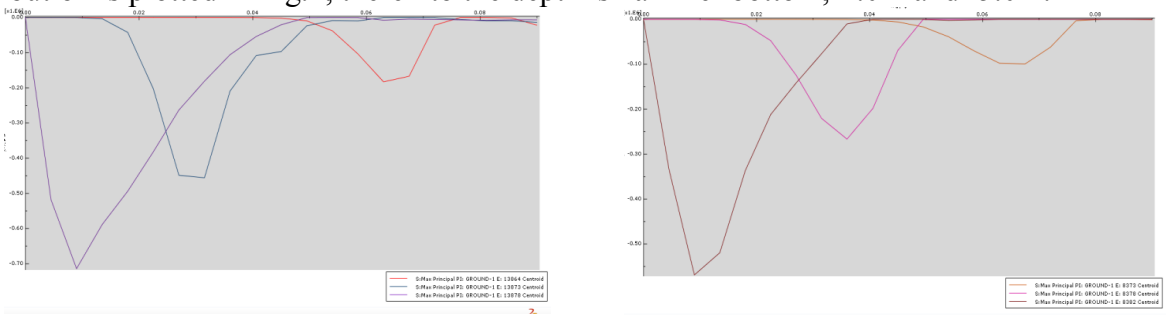
(a) 28t×10m Vertical Displacement Distribution Map

(b) 12t×24m Vertical Displacement Distribution Map

Fig.3 Vertical Displacement Distribution Map Under Different Weight and Height

It can be found from Fig.3 that as the hammer weight increases, the soil displacement increases, and ground surface heaves around the tamping pit, which is coincided with the actual.

4.2 Vertical Stress Distribution. Through the settlement displacement curve, the maximum displacement of each depth can be seen intuitively. The time variation of the vertical stress distribution is plotted in Fig.4, thereinto the depth is hammer bottom,-2.0m and -5.0m.



(a) Hammer Bottom,-2.0m,-5.0m under 28t×10m

(b) Hammer Bottom,-2.0m,-5.0m Under 12t×24m

Fig.4 Time Variation of the Different Depth Vertical Stress Distribution

It can be seen from the Fig.4 that as the depth increases, the maximum stress gradually decreases, and decreases rapidly when the stress reaches the peak, but these three kinds of impact force generated by the peak value are different. Fig.4(a) shows that the maximum stress of the hammer bottom is 0.72×10^{6}Pa. In Fig.4 (b), the maximum stress of the hammer bottom that is 0.57×10^{6}Pa is the minimum and the vertical stress distribution in other two positions decreases as the weight decreases. From the above points, it can be seen that the heavy hammer with small height of drop is superior to light hammer with large of drop under the same tamping energy condition. Therefore, if the conditions permit, try to use a heavy hammer with small height of drop. Thus, combined with the project, the 10m×28t can be selected as the actual construction parameters.

5 Summary

Simulated analysis is made on the progress of soft soil foundation by dynamic compaction in applying ABAQUS finite element software. Drucker-Prager yield criterion is presented in this paper. Compared the reinforcement effect of heavy hammer with small height of drop and light hammer with large of drop with that of different bottom area of the hammer, the following conclusions were drawn:

- The finite element analysis software ABAQUS can accurately simulate stress and displacements of the dynamic compaction on soft soil foundation reinforcement.
- Consolidation scope and depth of heavy hammer with small height of drop is superior to that of light hammer with large of drop under the same tamping energy condition.
- It is feasible to use the ABAQUS / Explicit module to calculate the contact between the hammer and the foundation.

Keywords: the partial equilibrium; the global optimum; the shortest circuit for three villages; Fermat point; the circumcenter.

Abstract: We explore the relationship between the partial equilibrium and the global optimum from the problem of the shortest circuit for three villages (PSCTV). Using the related properties of Fermat point and the circumcenter of the triangle, we can come to the conclusion that the partial equilibrium sometimes brings into correspondence with the global optimum but there is a great deal of difference between the two by analysing the difference between the sum of distances from Fermat point to all vertices and the ones from circumcenter to all vertices.

Introduction

The problem of the shortest circuit for three villages can be described "Three villages, due to limited conditions, intend to build a primary school together, and build the village roads from the school to all villages. Ask: where the school should be built in order to make the shortest length of roads? [1]" The corresponding mathematical problem is to find a point in the plane such that the minimum distances can be got from the point to three vertices of the triangle. This issue is clearly considered from prospective pavers' goals to minimize cost. In turn, from the student's point of view, for fairness, the school should address the position which has equal distance to three villages. What connection does exist between these two issues? And what will be the difference for the student's journeys in both programs? Here it will be explored.

Preliminaries

PSCTV can be transformed into a well-known Fermat point problem, and there exist a lot of research works about it. We only introduce some useful conclusions as follows.

Definition 1 We say that F is the Fermat point of the triangle if the minimum distances can be got from F to three vertices of the triangle.

Theorem 1 The Fermat point F of $\triangle ABC$ must be in its internal or boundary.

Proof. By contradiction, assume that F is in the external of $\triangle ABC$, then F must be in someone of six regions as shown in the Figure 1. If F is in region I, then the sum of distances from A to A,B,C are obviously less than the ones from F to A,B,C, so there is a contradiction. Similarly, the conclusions are true if F is in regions II and III. If F is in region IV, the sum of distances from the intersection of two lines BF and AC to A,B,C are less than the ones from F to A,B,C, so there is a contradiction. Similarly, the conclusions are true if F is in regions V and VI.

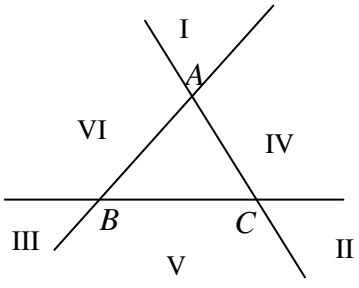

Fig. 1 Six regions in plane

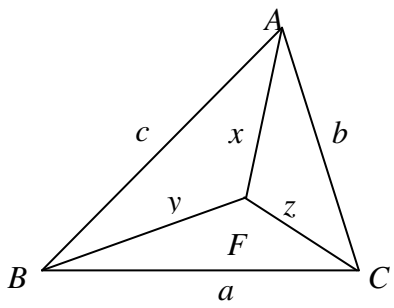

Fig. 2 The Fermat point F of $\triangle ABC$

Theorem 2[2] Assume that F is the Fermat point of $\triangle ABC$ as shown in the Figure 2, and $\max\{A,B,C\}<120^\circ$. Set $FA=x, FB=y, FC=z,$ then we have

$$x=\frac{b^2+c^2-2a^2+k^2}{3k},$$
$$y=\frac{a^2+c^2-2b^2+k^2}{3k}, \tag{1}$$
$$z=\frac{a^2+b^2-2c^2+k^2}{3k},$$

where a,b,c are sides of $\triangle ABC$, $k^2=\frac{1}{2}(a^2+b^2+c^2)+2\sqrt{3}S$, and S is the area $\triangle ABC$.

The sum of distances from the Fermat point to vertices of $\triangle ABC$ is denoted as d, then it is easy to get the following conclusion.

Corollary 1 $d=x+y+z=k=\sqrt{\frac{1}{2}(a^2+b^2+c^2)+2\sqrt{3}S}$. (2)

Let R be the radius of circumcircle of $\triangle ABC$, and the sum of distances from the circumcenter to vertices of $\triangle ABC$ is denoted as D, then $D=3R$. By Sine theorem $\frac{a}{\sin A}=\frac{b}{\sin B}=\frac{c}{\sin C}=2R$ and the formula for area of the triangle $S=\frac{1}{2}bc\sin A$, we derive $R=\frac{a}{2\sin A}=\frac{abc}{4S}$,

So, it is easy to get

$$D=3R=\frac{3abc}{4S}. \tag{3}$$

The relationship between d and D

We begin by discussing the value $D-d$. In [3], the distance from the circumcenter O to the Fermat point F of $\triangle ABC$ is given

$$|OF|^2=\frac{x^2\sin 2A+y^2\sin 2B+z^2\sin 2C}{\sin 2A+\sin 2B+\sin 2C}$$
$$-\frac{a^2\sin 2B\sin 2C+b^2\sin 2C\sin 2A+c^2\sin 2A\sin 2B}{(\sin 2A+\sin 2B+\sin 2C)^2}.$$

However, trigonometric function in the formula will bring much difficulty to getting the extreme value. We can directly give an expression for $D-d$ related to the sides a,b,c by (2) and (3) as follow

$$D-d=\frac{3abc}{4S}-\sqrt{\frac{1}{2}(a^2+b^2+c^2)+2\sqrt{3}S},$$

where $S=\frac{1}{4}\sqrt{4b^2c^2-(b^2+c^2-a^2)^2}=\frac{1}{4}\sqrt{(a+b+c)(a+b-c)(a+c-b)(b+c-a)}$.

For the sake of convenience, we first study $D-d$ in the isosceles triangle. Without loss of generality, set $b=c=1$, and a can change. So we have $a\in(0,2)$. So we can derive

$$D-d=\frac{3}{\sqrt{4-a^2}}-\sqrt{\frac{1}{2}(a^2+2)+\frac{\sqrt{3}}{2}a\sqrt{4-a^2}}.$$

Let $\frac{\mathrm{d}}{\mathrm{d}a}(D-d)=0$, we have

$$a^{16}-24a^{14}+255a^{12}-1544a^{10}+5727a^{10}-12432a^6+15025a^4-9312a^2+2304=0.$$

The above equation can be solved by Matlab software, and all real roots are as follows $a_1 = 1$ (3 multiple root)， $a_2 = 1.3726$， $a_3 = -1$ (3 multiple root)， $a_4 = -1.3726$.

Image of $D-d$ on a is as follows

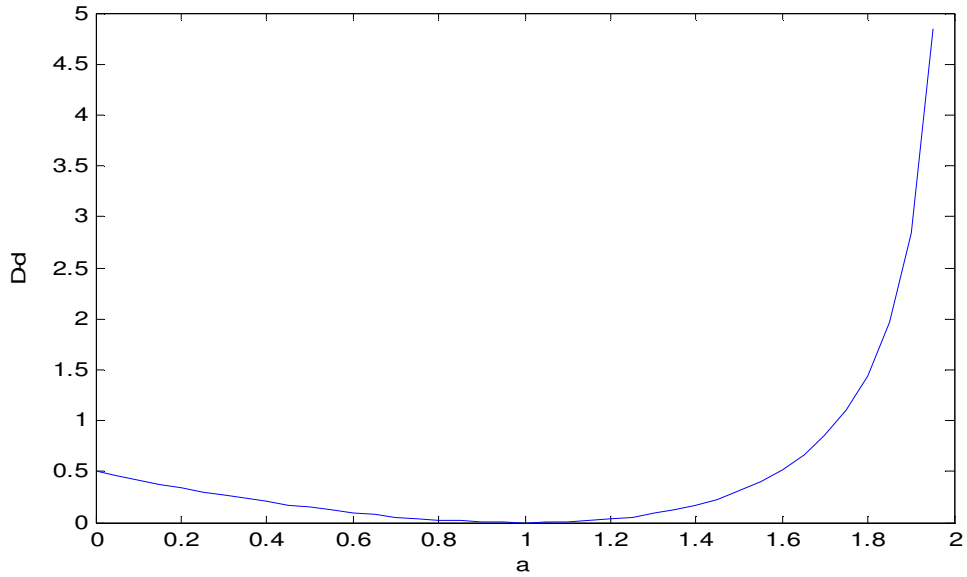

Fig. 3 Image of $D-d$ on a

As can be seen from the image, $a_1 = 1$ is the minimum of $D-d$, but not $a_2 = 1.3726$.

Let's discuss a few special cases.

(1) $A \to 0$. We have $a \to 0$，so $x = b = 1, y = z \to 0.d \to b = 1.$ In addition，we have O tends to the midpoint of $AB(AC)$，so $R \to \frac{b}{2} = \frac{1}{2}$. Hence

$$D - d \to \frac{b}{2} = \frac{1}{2}.$$

(2) $A = B = C = 60^\circ$. We have $a = b = c = 1$，so $x = y = z = \frac{\sqrt{3}}{3}b = \frac{\sqrt{3}}{3}.d = \sqrt{3}.$ In addition，we have $R = \frac{\sqrt{3}b}{3} = \frac{\sqrt{3}}{3}$. Hence

$$D - d = 0.$$

(3) $A = 90^\circ$. We have $\frac{\sqrt{2}}{2}a = b = c = 1$，so $x = \frac{\sqrt{3}-1}{\sqrt{6}}, y = z = \frac{2}{\sqrt{6}}.d = \frac{\sqrt{3}+1}{\sqrt{2}}.$ In addition，we have $R = \frac{a}{2} = \frac{1}{\sqrt{2}}$. Hence

$$D - d = \frac{2-\sqrt{3}}{\sqrt{2}} < \frac{1}{2}.$$

(4) $A = 120^\circ$. We have $x = 0, y = z = b = 1.d = 2.$ In addition，we have $R = b = 1$. Hence

$$D - d = 1.$$

(5) $A \to 180^\circ$. We have $B = C \to 0$，so $x = 0, y = z = b.d = 2b.$ In addition，we have $R \to \infty$. Hence

$$D - d \to \infty.$$

Thus, we can know that for (isosceles) acute triangles, $D-d$ gets the minimum value 0 when three sides are equal under the premise in unchanged. $D-d$ tends to the maximum value that is

the half of waist as the apex angle tends to zero. For obtuse triangle, $D-d$ increases monotonically with the increase of the apex angle, and $D-d$ tends to infinity as the apex angle tends to straight angle.

Summary

The above analysis coincides with a well-known mathematical assertion: the partial equilibrium (optimal) sometimes cannot guarantee the overall optimum for some practical problems. Excessive pursuit of a balanced individual may make the whole bear immeasurable loss.

Keywords: Face Recognition, Adaptive Neighborhood, DLLTSA, DALLTSA

Abstract. This paper proposes an adaptive discriminant linear local tangent space alignment algorithm DALLTSA. On the basis of LLTSA algorithm adding adaptive and discriminant gets DALLTSA.DALLTSA not only combines characteristics in DLLTSA that maintain the local geometry and meets the maximum between-class scatter matrix, but also dynamically selects K-neighbor better to reflect the degree of polymerization between samples. Finally, the face recognition experiments based on Gabor[1] filter and DALLTSA shows that this algorithm improves the recognition rate and robustness.

Introduction

With the rapid development of information technology, the application of high-dimensional data is wider, the number of high-dimensional data is also increasing, the dimensionality reduction of high-dimensional data is particularly more and more important .The main purpose of manifold learning is to restore the low-dimensional manifold structure from high-dimensional data. Existing linear local tangent space alignment algorithm LLTSA[2] is a linear optimization algorithm from LTSA. It solves the problem that LTSA can only be used to the training sample not the test sample. But LLTSA does not fully use the prior knowledge of the sample and also has problems about the selection of K-neighbor. Therefore, this paper proposes a DALLTSA algorithm.

In this paper,the face recognition experiments based on Gabor filter and DALLTSA shows that this algorithm improves the recognition rate and robustness.

Discriminant Linear Local Tangent Space Alignment Algorithm (DLLTSA)

The LLTSA algorithm is a linear unsupervised algorithm which we know the type information of the training samples. To make full use of the information, the literature[3] proposes the algorithm (DLLTSA) which takes class information into account and is called linear discriminant local tangent space alignment algorithm.

DLLTSA uses the between-class scatter matrix to modify the restrictions of the objective function of LLTSA. In order to maintain the local geometry and maximum between-class scatter matrix, the optimization problem of DLLTSA is as follows:

$$\begin{cases} \min\limits_{Y} tr(A^T XH_n BH_n X^T A) \\ \max tr(A^T S_b A) \end{cases} \tag{1}$$

s_b means the between-class scatter matrix. The objective function transformed from above conditions is

$$J(A) = \min \frac{tr(A^T XH_n BH_n X^T A)}{tr(A^T S_b A)} \tag{2}$$

The formula (2) is transformed into generalized eigenvalue problem:

$$XH_n BH_n X^T a_i = \lambda_i S_b a_i \tag{3}$$

Then we can get the eigenvalues and eigenvectors, if the corresponding eigenvectors of the eigenvalues $\lambda_1 \le \lambda_2 \le \lambda_3 \le ... \le \lambda_d$ is $a_1, a_2, a_3, ..., a_d$, the required projection matrix is

$$A = [a_1, a_2, a_3, ..., a_d] \tag{4}$$

Adaptive Algorithm

This paper calls adaptive neighborhood selection and LTSA modified model joint adaptive algorithm.

Selection of Adaptive Neighborhood. Literature[4] gives the standard for judging whether a neighborhood set of linear subspace determined by best-fit will approach the popular tangent space with high accuracy. According to the literature, the approximation standard of the tangent space is:

$$\left\| X_i - \left(x_i l_{k_i}^T + \tilde{Q}_i \Theta_i \right) \right\| \le \eta \left\| \Theta_i \right\|_F \tag{5}$$

In the formula, $X_i = \left[x_{i1}, x_{i2}, \ldots, x_{ik_i} \right]$; the matrix of the right singular vectors of the largest d singular values of $\left[x_{i1} - \tilde{x}_{i,}\ x_{i2} - \tilde{x}_i, \ldots, x_{ik_i} - \tilde{x}_i \right]$ is Q_i, $\Theta_i = \left[\theta_1^{(i)}, \theta_2^{(i)}, \ldots, \theta_{k_i}^{(i)} \right]$, $\theta_j^{(i)} = Q_i^T \left(x_{ij} - \tilde{x}_i \right)$; $\lambda_1 \ge \lambda_2 \ge \ldots \ge \lambda_{k_i}$ is the singular values in descending order of the matrix $X_i - \tilde{x}_i l_{k_i}^T$. Q_i is the corresponding right singular vectors of the maximum d singular value. The original standard is equivalent to:

$$\sqrt{\sum_{j \ge d} (\lambda_j)^2} \le \eta \sqrt{\sum_{j<d} (\lambda_j)^2} \tag{6}$$

So we get adaptive neighborhood selection strategy. This paper selects the K-neighbor under the condition of the known target dimension d. Specific steps are as follows:

(1)Select the largest number of sample $k = k_{\max}$ of the maximum neighborhood. Select k-near neighbors of x_i through the k-nearest neighbor principle. It can be expressed as $x_i^{k_{\max}} = \left[x_{i1}, x_{i2} \cdots, x_{ik_{\max}} \right]$.

(2)Select the k_i slightly larger than d as the current number of neighbors, Select the k_i neighborhoods of x_i and Composition of neighborhood set $x_i^{k_i} = \left[x_{i1}, x_{i2} \cdots, x_{ik_{ix}} \right]$.

(3)Calculate the singular value matrix $\left[\sigma_1^{(k_i)}, \sigma_2^{(k_i)} \cdots, \sigma_k^{(k_i)} \right]$ of $X_i^{(k)} - \tilde{x_i^{(k)}} l_k^T$ and arrange the singular value matrix in ascending order. After that, calculate the ratio of the minimum singular value and the sum of other singular values $\delta_i^k = \sqrt{\sum_{j=d} (\sigma_j^{(k)})^2} \Big/ \sqrt{\sum_{j<d} (\sigma_j^{(k)})^2}$. If $\delta_i^k > \eta$ (η is a parameter), at this time jump to the fourth step, expanding the neighborhood set. Instead, jump to the fifth step.

(4) Select g nearest neighbor points in the original largest neighbor set to expand to the smallest neighbor set, g takes the integer greater than 1, recalculate σ_i^k. If $\delta_i^k > \eta$ (η is a parameter), at this time jump to the fourth step, expanding the neighborhood set. Instead, jump to the fifth step.

(5)In the above neighborhood set, remove the relatively large neighborhood spot first. Recalculate δ_i^k. If $\delta_i^k > \eta$ (η is a parameter), proceed to the sixth step. Otherwise, continue into the loop of the fifth step.

(6) At this point, get the best neighborhood set. Neighborhood selection is completed.

Local Tangent Space Alignment (LTSA) Model Amendment. Through the literature[5], we can use the adaptive algorithm to modify the LTSA model in order to reduce the deviation. The minimization of the modified LTSA model is as follows:

$$\sum \frac{1}{k_i} \sum_{j=1}^{k_i} \left\| A_i (I - \frac{1}{k_i} l_{k_i} l_{k_i}^T)(I - \Theta^+ \Theta) D_i^{-1} \right\|_F^2 \tag{7}$$

The formula(7) is transformed into the eigenvalue problem:

$$\sum \frac{1}{k_i} \sum_{j=1}^{k_i} \left\| A_i (I - \frac{1}{k_i} l_{k_i} l_{k_i}^T)(I - \Theta^+ \Theta) D_i^{-1} \right\|_F^2 = \min_A tr(A \Phi A^T) \tag{8}$$

$\Phi = \sum_i \frac{1}{k_i} (S_i W i_i D i^{-1})(S_i W i_i D i^{-1})^T$, $\lfloor A_{1,\cdots,} A_N \rfloor S_i = \lfloor A_{i1,\cdots,} A_{i_{k_i}} \rfloor$, S_i is a 0-1 selection matrix. Moreover, $D_i = diag(\phi_1^{(i)}, \cdots, \phi_{k_i}^{(i)})$, $W_i = (I - \frac{1}{k_i} l_{k_i} l_{k_i}^T)(I - \Theta^+ \Theta)$.

According to the literature[6]. The best linear fitting is $\bar{x} + Q_i \theta_j^i$ for each different curvature match area set and the linear space Q_i is the best approximation to x_i .Geodesic curvature can be approximately estimated as the follow formula:

$$c_j^{(i)} = \frac{\arccos(\sigma_{\min}(Q_i Q_{i_j}^T))}{\left\| \theta_j^{(i)} \right\|} \tag{9}$$

The manifold learning may exist noise, so when the neighborhood point is too close to x_i , it will not be considered when we calculate the mean curvature. Therefore we use a threshold value σ_c to determine whether the point needs to be considered. Finally, the mean curvature can be obtained through the follow formula:

$$\overline{c_i} = mean \ \ \text{of} \ \left\{ c_j^{(i)} \middle| x_j^{(i)} \in x_{i,} \left\| \theta_j^{(i)} \right\| > \sigma_c \max_{j \le k_i} \left\| \theta_j^{(i)} \right\| \right\} \tag{10}$$

So we can get an estimated for $\phi_j^{(i)}$,

$$\phi_j^{(i)} = \overline{c_i} \left\| \theta_j^{(i)} \right\|^2 \tag{11}$$

Face Recognition Algorithm Based on Gabor Filter and DALLTSA

The face recognition experiments are based on Gabor filter and DALLTSA. The specific steps are as follows:

Suppose $X = \{x_1, x_2, ..., x_n\}$ as n pieces (c classes in all) of training images, x_i is the image matrix.

(1) Filtering each face images with Gabor filter in different frequencies and directions to get a lot of groups of Gabor features, n and m respectively represent number and frequency.

(2) Sampling for Gabor features of each group in groups and blocks to get lower dimension characteristics getting the composition of an image matrix c_i , the combination of methods is mentioned above.

(3)For the n samples set $C = \{c_1, c_2, ..., c_n\}$, use $(2D)^2 PCA$ to reduce dimension, then each image matrix is connected by line end to end, each image constitutes a column vector x_i , the matrix $X = [x_1, x_2, ..., x_n]$ is composed of n pieces of pictures.

(4) A secondary feature extraction is to use DALLTSA for feature extraction.

(5)Classify the test samples using the above four steps to obtain a low-dimensional feature vector images and then use the classifier for classification.

Comparison and Analysis of the Experiment Results

In this paper, the experiment uses a self-built library of 120 individuals, 20 photos per person, including all kinds of information gestures, facial expressions and so on. For each person, we

randomly sample 10 images as training samples, take the remaining 10 as test samples, cycle 20 times and take the average rate as the correct recognition rate. When adding adaption to the algorithm we use the letter A, when the discrimination we use the letter D.

The results are the variation of dimension followed by the average recognition rate of the three algorithms (ALLTSA, DLLTSA, DALLTSA) based on face database. The experiment results are shown in Figure.1:

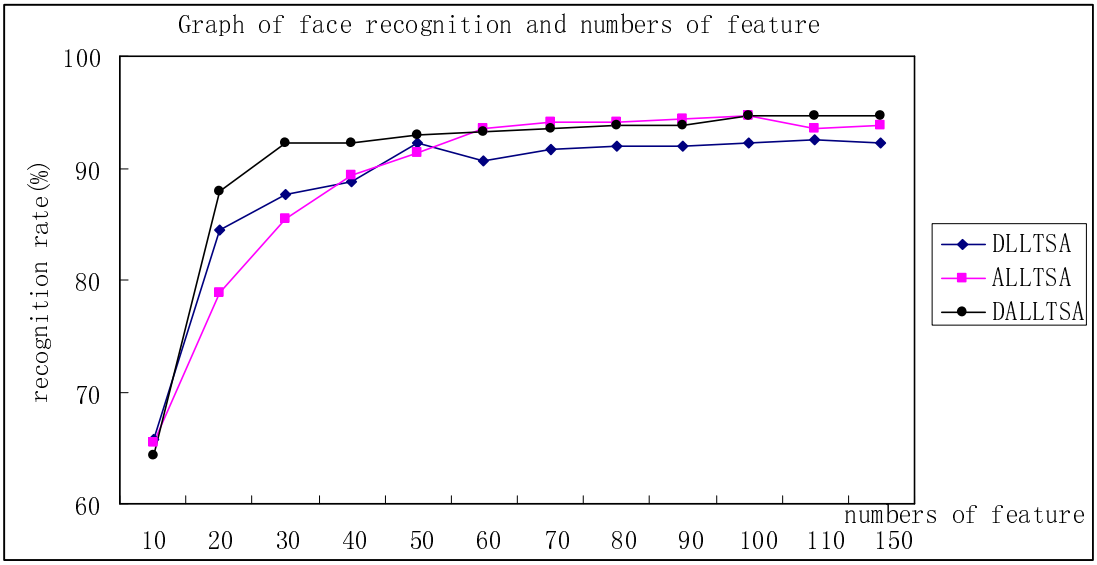

Fig.1.The variation of dimension followed by the average recognition rate of the three algorithms based on face database

From the figure above, between10-60 dimension the algorithm DALLTSA, have improved the recognition rate compared to DLLTSA and ALLTSA. After 60 dimensions their recognition rates approach a straight line basically reaching to the maximum recognition rate.

Summary

The DALLTSA algorithm can play a great role in the improvement, it can not only maintain the local geometry and meet the maximum between-class scatter matrix , but also dynamically select k-neighbor better to reflect the degree of the polymerization between the samples.

Therefore, the DALLLTSA algorithm can well improve the performance and robustness of the algorithm.

Research on the traffic rules of the freeway

Yuxuan Jiang

North China Electric Power University, Baoding,071000, China,

email:jennyloverock@163.com

Keywords: Driving Rules of Freeway; Overtaking; Cellular Automaton

Abstract. This paper mainly studies on the superiority of a driving rule of freeway. Using the theory of cellular automaton, we definite two indexes and make evaluation and analysis of the Keep-Right-Except-To-Pass rule under different traffic load conditions. At last, comparing with one of the other rules, we prove the superiority of the common rule.

Introduction

In countries where driving automobiles on the right is the rule (that is, USA, China and most other countries except for Great Britain, Australia, and some former British colonies), multi-lane freeways often employ a rule that requires drivers to drive in the right-most lane unless they are passing another vehicle, in which case they move one lane to the left, pass, and return to their former travel lane.[1]However, compared to the other rules, does the Keep-Right-Except-To-Pass rule really has advantages in some ways? Perhaps most people haven't do research on it.

In this paper, we make an analysis on two driving rules. One is the Keep-Right-Except-To-Pass rule, the other is the rule that both of the lane are allowed to drive on, but no overtaking.

To evaluate a traffic rule, we need to consider both of the quantity of traffic flow and the safety. These two parameters are very closely related .So we established two evaluation indexes to represent the security and the traffic capacity.[2]

In this paper, we use the theory of cellular automata to make a simulation of the actual traffic situation of freeway. We compared the safety of two rules under different traffic loads. Finally, we come to a conclusion.

The theory of cellular automaton

A cellular automaton (pl. cellular automata, abbrev. CA) is a discrete model studied in computability theory, mathematics, physics, complexity science, theoretical biology and microstructure modeling. Cellular automata are also called cellular spaces, tessellation automata, homogeneous structures, cellular 3structures, tessellation structures, and iterative arrays. [3]A cellular automaton consists of a regular grid of cells, each in one of a finite number of states, such as on and off (in contrast to a coupled map lattice). The grid can be in any finite number of dimensions. For each cell, a set of cells called its neighborhood is defined relative to the specified cell. An initial state (time t=0) is selected by assigning a state for each cell. A new generation is created (advancing t by 1), according to some fixed rule (generally, a mathematical function) that determines the new state of each cell in terms of the current state of the cell and the states of the cells in its neighborhood. Typically, the rule for updating the state of cells is the same for each cell and does not change over time, and is applied to the whole grid simultaneously, though exceptions are known, such as the stochastic cellular automaton and asynchronous cellular automaton. [4]

The Keep-Right-Except-To-Pass rule

When vehicles appear in the freeway entrance randomly, compare the random number generated by the computer with the probability P vehicles entering the freeway. When the random number is less than the probability P, vehicles enter into the lane 1.Then we record the number N of vehicles entering into the road. We set the random speed of vehicles entering the freeway in the

range of [2, 5], 2 as the lowest speed, 5 as the highest speed limit. We record the location of car as x (i,j,t),the speed of vehicle as V. We set the step of simulation as 1s,the total simulation time as Ts .Each time the step of time is forward 1 s, we judge the distance $gap_n(t)$ between the two close cars, when $gap_n(t)$ is shorter than the threshold 2, then the car chooses to overtake. It moves to the left lane to pass, and return to their former lane when the overtaking is finished. When the distances between the continuous three cars are both less than the threshold. It may result in a traffic jam .The vehicle trapped in a traffic jam cannot go through this journey in the end. We record the time of the traffic jam N1 and the time of the free passage N2.

The both of lane are allowed to drive on, but no overtaking rule

We definite a freeway the length of which is L. The vehicle appears in the freeway entrance by the probability P. We record the number N of the vehicle entering into the road. We set the random speed of vehicles entering the freeway in the range of [2, 5], 2 as the lowest speed, 5 as the highest speed. We record the location of car as x(i,j,t) and speed of car as V. We set the step of simulation as 1 S, the total simulation time as T s .Each time the step of time is forward 1 s ,judge the distance $gap_n(t)$. If $gap_n(t)$ is shorter than the threshold, It may result in a traffic jam .The vehicle trapped in a traffic jam cannot go through this journey in the end. We record the time of the traffic jam N1 and the time of the free pass N2.[5]

The definition of evaluation indexes

In this process, we notice that there are two indexes. we make the definition of them as follows.

(1)The probability of traffic jams: When a car goes through the freeway with a certain length, it drives faster than the car in front of it and cannot overtake .The probability of this case is called the probability of traffic jams. It's obvious that the index is related to the security. So we use this index to evaluate the traffic safety.

$$\text{the probability of traffic jams} = \frac{the\ time\ of\ traffic\ jams}{the\ number\ of\ the\ cars\ entering\ the\ freeway}$$

(2)The probability of free passage: The probability of a car which is unlikely to be trapped in a traffic jam.This index is evaluated the traffic capacity.

$$\text{the probability of traffic jams} = \frac{the\ number\ of\ free\ passage}{the\ number\ of\ the\ cars\ entering\ the\ freeway}$$

The Simulation Parameters

In the simulation, we set the following Parameters

(1)the probability of the car entering the road pp: We value the probability of the car entering the road as 0.05, 0.15, 0.25, 0.35, 0.45, 0.55, 0.65, 0.75, 0.85, 0.95

(2) The length of the cellular: We define a one-dimensional lattice to represent a single lane. The length of the freeway L is 1 mile, which is divided into 250 cells, namely each cellular actual length is 21 feet. The actual length of the cellular is slightly larger than the average length of car (about 15 feet)

(3) The step of the simulation time dt: We set it as 1 s.

(4) The total time of simulation: We set the time as 500s.

(5) The minimum speed V_{min}:We set the minimum speed as 2 celluar/s,if the step of the simulation is 1s,the corresponding minimum speed is 30 mph, almost equal to the lower limit speed of the freeway, corresponding to V_{min}= 2 celluar/s .We use cell/S as the unit .

(6) The maximum speed V_{max} :We set the minimum speed as 5 celluar/s,if the step of the simulation is 1s,the corresponding min V is 72 mph,equal to the higher limit speed of the freeway, corresponding to V_{max}=5 celluar/S

(7) The random speed entering the road V_r :$V_r = V_{min} + rand \times (V_{max} - V_{min})$

(8) The thresholds of overtaking conditions: We set the thresholds as 2.It's consistent with the actual situation.[6]

The result of the simulation:

The Figure 1 shows the dynamic simulation process of cellular automata.

The second rule seems to increase the number of lanes which are allowed to drive on, but is it safer than the Keep-Right-Except-To-Pass rule?

To analyze which kind of rule is the better in different load conditions, we draw the curve of the two rules above under the same coordinate system. The abscissa represents the probability of a car entering the freeway(namely the load) .If the intersection point exists, this mean the two rules have the same probability of traffic jams(namely the same level of security).The curve below the intersection point has the better level of security.

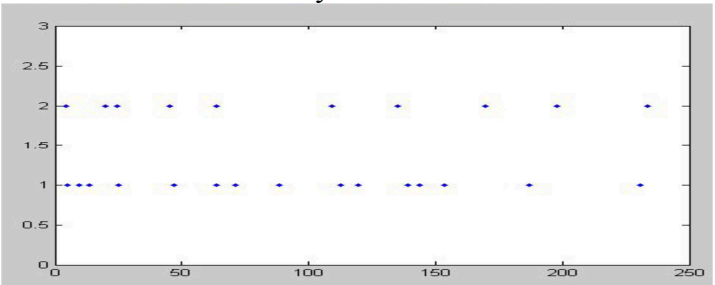

Figure 1 Dynamic simulation figure of cellular automata

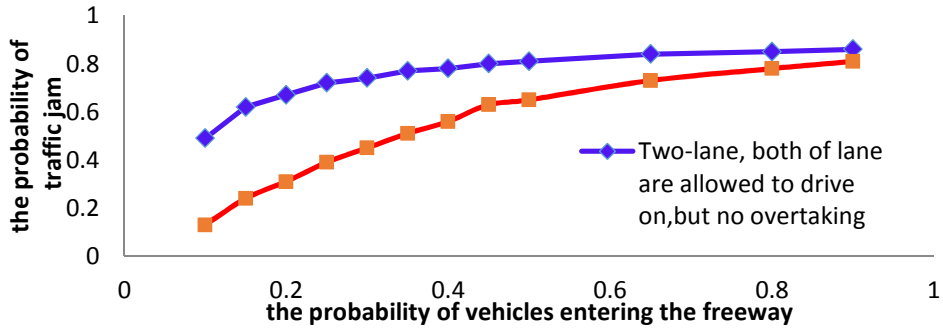

Figure 2 The probability of the traffic jams of the two rules

We can find out from the Figure 2 that when the load is low, the security of the Keep-Right-Except-To-Pass rule is better. What's more, the advantage is obvious. When the load is high, the Keep-Right-Except-To-Pass rule is still safer but the advantage gap is narrowed. So, we can conclude that the Keep-Right-Except-To-Pass rule which is used in most countries is applicable to the freeway.

Conclusion

We conclude that no matter the traffic load is low or high, the Keep-Right-Except-To-Pass Rule is applicable in most countries. It can improve the quantity of traffic flow and the security to a certain extent. Though the advantage is not obvious in the high load, we cannot find an alternative at present.

[a]why9433@163.com, [b]sgliu@163.com

Keywords: Collision detection, AABB, octree, space division

Abstract. NC lathe controls the action of the lathe through program control system, while programming mistakes may lead to collisions between NC lathe cutters and workpieces or fixtures. A collision detection system judge whether there are collisions ahead of time by means of reading the information of shape and pose of objects in processing environment, building a space model using CSG and acquring the movement intension of objects. Dividing the modeling space into space nodes using octree, building AABBs of objects to be tested and locating them at certain space nodes, only objects at the same node or the same father node need to be tested, thus testing speed is raised.

Introduction

High precision, complex movement track and fast speed are features of NC process, a virtual NC lathe simulates the actual NC process environment in a computer and predict whether there is a collision that should not happen between moving cutter, workpieces and tool parts, thus damages of lathe equipment are prevented. Collision detection algorithm based on image space is a kind of relatively new collision detection algorithms, it can effectively use graphics hardware rendering acceleration to improve the efficiency of collision detection algorithm. Trianglated mash surface was used to express 3D solid objects [1], while the huge quantity of triangles lead to expensive time consuming, so the precision contradicts with speed.

Real-time and high-efficient are key factors of collision detection, so that the division of process environment is required, and the possibilities of collisions between objects in different nodes or father nodes are excluded, thus times of pairwise test are decreased and efficiency is improved.

Collision Detection Algorithm

The collision detection algorithm can be classified into two classes: bounding box and space division. The main idea of bounding box is to use a simple geometry object like cuboid and sphere to include a virtual object, and substitute the bounding box for the virtual object in the test[2], the objects that must not intersect are excluded firstly, then a precise collision detection of objects that may intersect will be operated, thus test time are reduced; the basic thought of space division is that the space are divided into different regions, only nodes that may arouse concern are noticed while other nodes are not considered, thus the pairwise test numbers are decreased [3].

Axis-Aligned Bounding Box. Axis-aligned bounding box (AABB) is defined as a minimum hexahedron including the object, each edge of which is parallel to a coordinate axis, and AABB is one of the most popular bounding boxes [4]. Its most outstanding character is that fast intersection test can be accessed, for the reason that only coordinate values are compared, while there exists a disadvantage of bad closeness to objects with inclined axises. This paper use "maximum-minimum" method to express an AABB, the intersection test can be accomplished by judging the relationship of six parameters. If the projection of two AABB intersect on every coordinate axis, then the two AABBs intersect in 3D space; as long as there exists an axis on which the projection don't intersect, the two AABBs don't intersect. So the test between AABBs needs 6 times of comparison at most, and codes are as below:

```
class AABB
{double AABB_x_max,AABB_x_min; double AABB_y_max,AABB_y_min;
        doubleAABB_z_max,AABB_z_min;  };
int AABB::testAABBAABB(AABB b)
{       if(AABB_x_max<b.AABB_x_min||AABB_x_min>b.AABB_x_max)return 0;
        if(AABB_y_max<b.AABB_y_min||AABB_y_min>b.AABB_y_max)return 0;
        if(AABB_z_max<b.AABB_z_min||AABB_z_min>b.AABB_z_max)return 0;  return 1;}
```

The Constructive Solid Geometry (CSG) representation allows users to define complex 3D solid objects by hierarchically combining simple geometric primitives using boolean operations [5]. Based on the characters of NC lathe process environment and shape of objects to be tested, CSG can be used to build the model. Considering the "maximum-minimum" method, by computing the maximum and minimum value of the projection of object on three axises, the bounding box can be obtained. As to the primitives whose main axis is parallel to a certain coordinate axis or coordinate plane, its projection can be computed by simple addition and subtraction of its parameters; as to those whose main axis direction is non-special, further operation should be conducted. After building the bounding boxes of primitives, hierarchical bounding box can be built by means of "bottom-to-up".

Cite a cone frustum as an example, for the reason that a cone frustum is of curved surface shape that is more complex than plane-surface-object. Given radius of up surface r_1, radius of bottom surface r_2(when $r_1 = r_2$,the cone frustum becomes a cylinder), center point (O_x,O_y,O_z), height h, and the direction of main axis can be classified into three condition:

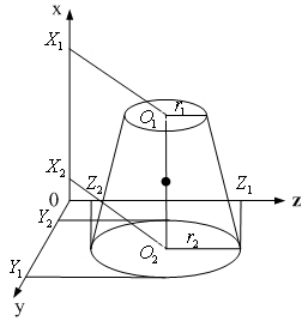

Fig.1 Main axis parallel to *x*-axis

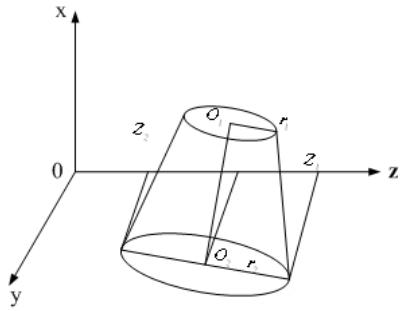

Fig. 2 Main axis parallel to *xoy* plane

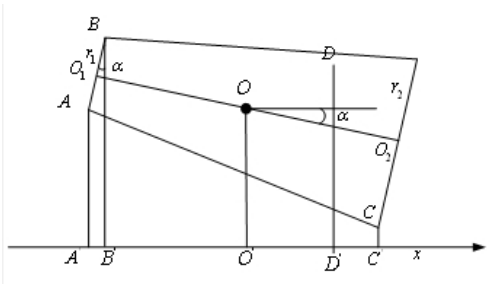

Fig. 3 Projection of main axis onto *x*-axis (main axis parallel to *xoy* plane)

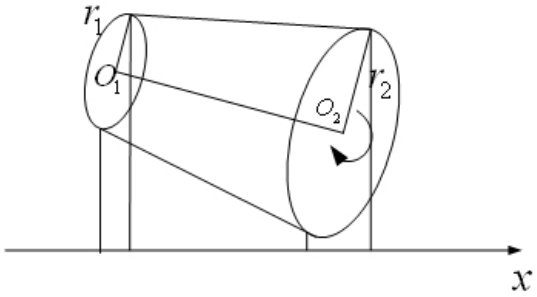

Fig.4 Main axis direction non-specia

1) The Main Axis Parallel to *x*-axis

As the main axis is parallel to *x*-axis，the projection of the cone frustum onto *x*-axis can be regarded as its projection of main axis onto *x*-axis，so the projection interval is $[O_x+1/2h,O_x-1/2h]$, the two surface can be proved to be parallel to *y*-axis and *z*-axis, so projection of the cone frustum onto *y*-axis and *z*-axis can be regarded as its projection of two planes on those two axises. The projection interval on *y*-axis is $[O_y+r_{max}, O_y-r_{max}]$, and the projection interval on *z*-axis is $[O_z+r_{max}, O_z-r_{max}]$, when $r_{max}=\max\{r_1,r_2\}$.

2) The Main Axis Parallel to *xoy* Plane

As the main axis is parallel to *x*oy plane，similarly the projection interval on *z*-axis is $[O_z+r_{max}, O_z-r_{max}]$. The projection on *xoy* plane is a isosceles trapezoid, cite *x*-axis as an example, given the

angle between the axis of trapezoid and *x*-axis is α , project the trapezoid to *x*-axis, and the projection (A',B',C',D') of the four vertexes of the trapezoid (A,B,C,D) form an interval, whose vertexes are the maximum and minimum values of the bounding box on *x*-axis.

3) The Main Axis Direction Non-Special

Cite *x*-axis as an example, the projection interval on the axis can be regarded as the largest interval between its projection of two planes on the axis, while the plane can be seen as a region that is formed by rotating a line segment with the length of the plane radius around the frustum axis, with the rotating center being the plane center. While the angle between the line segment and *x*-axis is the minimum, its projection on *x*-axis is the longest. The vertexes of this interval is the maximum and minimum value of the bounding box on *x*-axis. Fig.6 shows the box of a cone frustum obtained by this algorithm through OpenGL/GLUT graph library.

Octree Division of Space. Octree is a space division algorithm based on tree shape structure, each node of the tree stands for a model space, and each non-leaf node includes 8 child nodes. Root node is the minimum cube containing the whole scene, divide the cube along *x,y, z*-axis evenly into 8 child cubes, and go on to recursively divide them until the tree structure reach the deep designed[6]. The node information includes the center point and width of the model space, the pointers pointing its 8 child nodes and the linked list of objects in this node.

The space octree need to be traversed to insert the objects in the space into space nodes. Starting at the root node, first judge whether current node owns child nodes: if not, insert the object into the current node; if yes, then judge whether the object intersects with two or more child nodes of the current node: if yes, insert the object into current node; if not ,or in other words ,the object is totally included in a certain child node, then regard this child node as current node and traversely judge. Each object in the non-empty node need to be tested with all the objects in the subtree of this node.

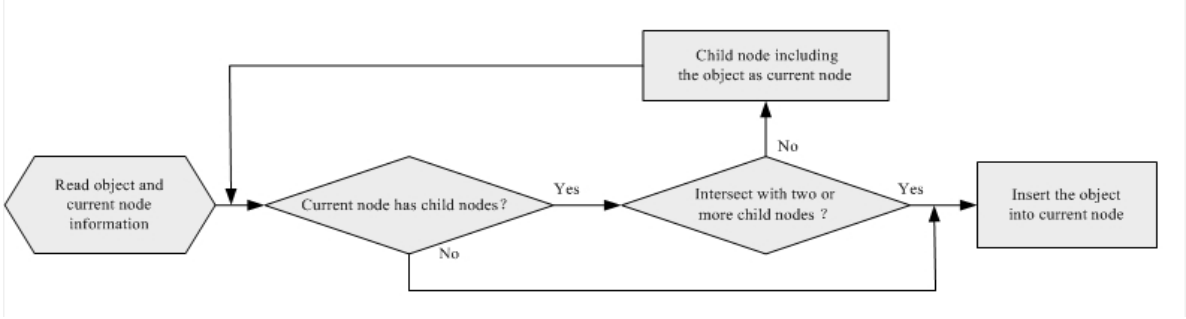

Fig.5 Object insertion flow

Experiment and Conclusion

Verify the validity of bounding box algorithm;divide the environment into octree space and insert objects into space nodes; find the node where the tested object locates and test the object with all the objects in the node and its subnodes. The experiment has been implemented under the circumstance of VC++6.0. The octree was set at a certain deep according to the size and number of objects in the environment , and the objects were quickly located in the octree. The use of AABB and octree algorithm reduced the test time and pairwise test times, and efficiency was increased. While the CSG can only express simple-shape objects that consist of basic primitives, and a more general geomertric representation still need to be applied. This algorithm is a static state collision detection, and the building of active octree remains to be studied.

A Visual Hiding Algorithm Based on Human Visual System

Rui Dong[1, a], Daoshun Wang[1, b]

[1]Department of Computer Science and Technology, Tsinghua University, Beijing 100084, China.

[a]dzippor@sina.com, [b]wangdaoshun@gmail.com

Keywords: Information hiding, HVS, image edge and texture, inverted image.

Abstract. Image information hiding is a way of concealing secret information within another image or file. The previous researches of image information hiding extract secret by calculating. An algorithm based on HVS (Human Visual System) is proposed in this paper. We first decide the embedding region and embedding strength of secret image based on edge and texture information. Then, a pair of invert images is chosen as the cover images, and the stego images are constructed by modifying the pixels of the cover images through the proposed criterion. Correspondingly, the secret image can be recovered through overlaying the two stego images.

1 Introduction

The human visual system has less sensitivity on redundancy of the whole image, partial or slight changes of the image. By taking the advantage of these features, image information hiding embeds the secret into carrier image under the condition that not affecting the transmission quality of the carrier image. Naor and Shamir[1] first proposed the scheme of visual cryptography in 1994. The secret information can be retrieved by a simple superposition. Lee et al.[2] hided information within meaning stego images based on HVS with no pixel expansion. Yamaguchi[3] proposed a continuous hue based scheme using parallel error spread and optimum hue mapping. Both of the two schemes have no pixel expansion, but the cover image can be seen partially in the background of recovered image during recovering. Refs. [4-6] use the digital halftoning to achieve the goals of no pixel expansion. Hou[7] proposed the asymmetric watermarking scheme based on HVS.

In this paper, we propose an visual hiding algorithm scheme based on HVS. A pair of invert images is used as the cover images in this algorithm, and the background color of the recovered image is black, which greatly improves the visual quality the secret image.

2 Related Work

Visual Cryptography is an effective method of information hiding. Hou[7] proposed the asymmetric watermark algorithm based on HVS, and the complementary matrixes Naor and Shamir used are shown as follow:

$$\begin{bmatrix}1 & 0\\1 & 0\end{bmatrix}\begin{bmatrix}0 & 1\\0 & 1\end{bmatrix} \quad \begin{bmatrix}1 & 1\\0 & 0\end{bmatrix}\begin{bmatrix}0 & 0\\1 & 1\end{bmatrix} \quad \begin{bmatrix}1 & 0\\0 & 1\end{bmatrix}\begin{bmatrix}0 & 1\\1 & 0\end{bmatrix}$$

Vertical Horizontal Cross

Hou's algorithm is shown as follow, and an example is given in Figure 1:

Input: $2^{c-1} \times 2^{c-1}$secret image *S*, cover image C

Output: stego image S_1, S_2, cover image C

Construction:

Step 1: if $S(i,j) = 0$, randomly fill the 2×2 blocks of S_1, S_2 into the above matrixes; else if $S(i,j) = 1$, randomly fill the 2×2 of S_1 into the above matrix, and fill S_2's blocks into S_1's complementary matrix, until S_1, S_2 are constructed.

Step 2: if $S_1(i,j) = 1$, decrease the gray scale $C(i,j)$ by 8, until C is constructed.

(a) (b) (c) (d) (e)

Fig. 1 (a) Cover image, (b) original secret image, (c) (d) stego image 1 and 2, (e) recovered image

In image information hiding, the visual quality of the stego image is an important measurement, PSNR is widely used for measuring visual quality of stego image[9,10]. PSNR's definition is shown as follow:

$$PSNR = 10 \cdot \log_{10} \frac{(255)^2}{MSE} dB \tag{1}$$

MSE represents the mean square error between the cover image and stego image：

$$MSE = \frac{1}{M \times N} \sum_{i=1}^{M} \sum_{j=1}^{N} (x_{i,j} - y_{i,j})^2 \tag{2}$$

where $x_{i,j}$ and $y_{i,j}$ represent the pixel value of cover and stego image respectively, $M \times N$ represent the size of image. Generally, MSE can be used to evaluate the quality of binary image.

In Hou et al.'s algorithm, the PSNR of the stego image is 26.144dB, and we can see that the stego image has serious artifacts comparing with the original cover image.

3 Proposed Visual Hiding Algorithm

In this section, the detail of the proposed algorithm will be shown. Our algorithm is similar to Hou's algorithm[8], both of them are based on HVS. Firstly, the cover image is halftone processed with error diffusion algorithm. Then embed the secret image into the texture and less visual sensitive regions of the cover image.

3.1 Texture and Edge.

According to the HVS characters, the process strength of the stego image is affected by the texture complexity, the more complex the texture is, the higher the available process strength is, correspondingly, the higher the recovered image quality is. So it is effective to use the edge and texture to decide the embedding region and strength.

The entropy[9] of image represents the image's average information amount, and it can be used to evaluate texture's complexity. Variance is a measure for edge in images, and generally, the variance around edge is much bigger. Based on the relation between entropy and variance, we can divide the region feature into the following four categories:

Table 1 Feature categories based on entropy and variance

	Smooth	Edge	Texture	Others
Entropy(*H*)	small	big	large	small
Variance (*Var*)	small	big	small	large

Through the above, we can conclude that regions with complex textures and less edges are the ideal regions for embedding. Secret embedding needs regions that contain a lot of textures, so the entropy will be taken into consideration firstly.

3.2 Construction of the Algorithm.

The cover images used in this algorithm are two halftoned images with invert color to each other. The pixels of the input secret image *S* are black, and the recovered image has the invert color, which greatly increases the contrast.

Let secret image be *S*, let cover image 1 and cover image 2 be I and I' respectively. Let stego image 1 and 2 be S_1 and S_2 respectively, and T be the threshold of detection. Let $M_1(M_2)$ be the

modification degree of the first(second) pixel in the 1×2 block of stego image 1. Let $M'_1(M'_2)$ be the modification degree of the first (second) pixel in the 1×2 block of stego image 2.The algorithm use T to constraint the modification of the current pixel. Table 2 give the detail criterion for modification:

Table 2 Criterion for pixel modification

S	I	I'	condition	S_1	S_2
[1 1] [1 0] [0 1]	[1 0]	[0 1]	Probability: 1/2	[1 0]	[1 0]
	[0 1]	[1 0]		[0 1]	[0 1]
	[0 0]	[1 1]	$M'_1 \geq T$	[0 0]	[1 0]
			$M'_1 < T\ M'_2 \geq T$	[0 0]	[0 1]
	[1 1]	[0 0]	$M_1 \geq T$	[1 0]	[0 0]
			$M_1 < T\ M_2 \geq T$	[0 1]	[0 0]
[0 0]	without any modification				

In the modification criterion is based on the connected region's white pixels. And the modification degree is to avoid adhesion. A pending pixel has 8 neighbor black pixels in continuous 3×3 connected region. In this paper, we set weight for the other 8 pixels in the connected region to decide the modification degree $M(i,j)$. Let function $B(x,y)$ return 0 on $x=y$, return 1 on $x \neq y$, then the modification degree of $A(i,j)$ is:

$$M(i,j)=\sum_{r=-1}^{1}\sum_{t=-1}^{1} w(A(i,j),A(i+t,j+t))B(A(i,j),A(i+t,j+t)) \quad (3)$$

where $w(x,y)$ represents the weight of the pixel on coordinate (x,y), and the weight assigning criterion is shown as following:

a) 5 for pixel with no modifications.
b) For modified pixels: 3 for pixels in diagonal direction, 2 for pixels in horizontal and vertical directions.

Assigning different weights for pixels with and without modifications is to decrease the possibility of adhesion caused by modifying neighbor pixels. Treating horizontal and vertical pixels differently is for the reason that human eyes are more sensitive to horizontal and vertical pixels than the diagonal ones. The detail algorithm is given as fellow.

Input: original secret image *S*, grayscale image *C*
Output: stego image S_1, S_2
Construction:
Step 1: Halftone process *C* to get cover image *I* and the invert image *I'*, let $S_1 = I, S_2 = I'$.
Step 2: Decide the start coordinate of the stego region: *X,Y*.

(1) Define a new structure "*D*", which contains the elements of coordinate, entropy and variance.

(2) Scan *C* pixel by pixel with a sliding window is size *S*, and record the entropy, MSE and start coordinate of the region to an array Arr with *D* as element and in size *N*.

(3) Sort the array Arr in entropy descending order. Get the element with the biggest MSE as D_E from the first $\lceil \partial N \rceil$ elements in Arr($0<\partial<1$), record its coordinate as *X,Y*

Step 3: Scan *S* with row step size 1 and column step size 2 to get neighbor pixels $S(i,j)$, $S(i,j+1)$, and the the corresponding cover image $I(i+X-1,j+Y-1)$ and $I(i+X-1,j+Y)$.
Step 4: Calculate the modification degree for $S(i,j)$, $S(i,j+1)$, $I(i+X-1,j+Y-1)$ and $I(i+X-1,j+Y)$
Step 5: According to the table 2, then modify S_1 and S_2 according to the modification degree and detection threshold *T*.

Example 1: original secret image *S*: $[1\ \ 0\ \ 1\ \ 1\ \ 0\ \ 0]$, cover image *I*: $\begin{bmatrix} 1 & 0 & 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 1 & 1 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 & 1 & 1 & 0 & 0 \end{bmatrix}$, set all the initial weights to 5, ideal embedding position: *X*=2, *Y*=2. Sequentially scan two

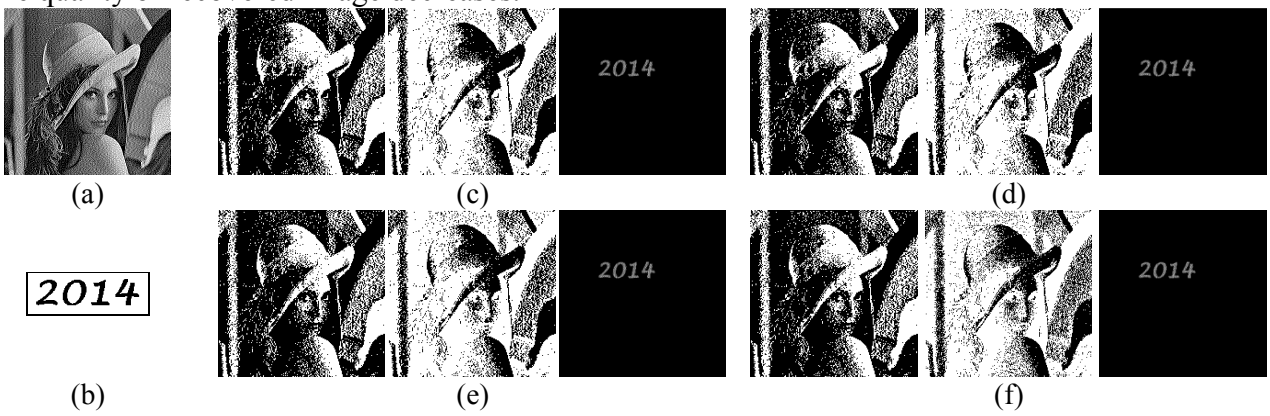
consecutive pixels of the original secret image, detection threshold T=20, the stego image is constructed as follows:

1. $S = [1 \quad 0]$, $I = [0 \quad 0]$, $I' = [1 \quad 1]$. The modification degree of the first pixel of S_2: $M'_1 = 3 \times 5 = 15 < T$, then this pixel cannot be modified. The modification degree of the first pixel of S_2: $M'_2 = 4 \times 5 = 20 \geq T$, then this pixel can be modified. Modify the corresponding block of S_2 to $[0 \quad 1]$, and mark this pixel as "modified". The recovered result: $R = [0 \quad 1]$.
2. $S = [1 \quad 1]$, $I = [1 \quad 0]$, $I' = [0 \quad 1]$. Permute the two consecutive pixels values of the S_1 or S_2 with probability 0.5, in this process modify the corresponding block of S_2 to $[1 \quad 0]$, and mark the pixel as "modified". The recovered result: $R = [1 \quad 0]$.
3. $S = [0 \quad 0]$. No need to modify.

4 Comparison and Discussion

4.1 Experimental Results.

By observing Figure 2, it is convenient to see that as T differences, The quality of the stego images and the recovered image changes. Figure 2 is the experimental results by different T. By observing experimental results, when T=0, the stego image will leak the information for the secret image. So the appropriate value for T is important. As T increases, the quality of stego images increase while the quality of recovered image decreases.



(a) (c) (d)

(b) (e) (f)

Fig. 2 Experimental results. (a) cover image, (b) secret image, (c)-(f) stego images and recoverd image are generated with T=0, 10, 21, 25

MSE can be used to evaluate the quality of binary image. The smaller the MSE, the better the quality of stego images. The secret have the number of black pixels is 2838. This paper defines the number of the meaningful pixels as information amount, which can be counted to describe the quality of the recovered image. The comparison result is summarized as Table 3.

Table 3 MES for stego images with different T

T	Stego 1	Stego 2	Information amount
0	300.1413	239.5167	1553
10	260.7013	235.6482	1345
21	174.6277	170.1628	843
25	156.5200	159.0005	729

By observing Table 3, it is convenient to see that as T increases. The MSE of the stego images increase and the information amount of the recovered image increase (Because of the stego 2 is inverse, when calculating the MSE of the stego 2, we should use the inverted cover image). By the experimented results, different texture complexity of image result in different embedded effect. So the ideal value of T is variable in different cases. By observing the experimental results, when T=21, the experimental result is ideal.

4.2 Comparison with Hou's Algorithm.

In this section, we compare the proposed algorithm with Hou's algorithm in four typical aspects: (1) the type of cover image, (2) whether require extra pixel expansion or not, (3) whether require the stego images meaningful or not, and (4) the quality of recovered image.

Table4 Comparison of the proposed algorithm and Hou's algorithm

Algorithms	Cover images	Pixel expansion	Meaningful		The quality
			S_1	S_2	
Hou's algorithm	Gray	m=4	Yes	No	Less poor
Our algorithm	Halftone	m=1	Yes	Yes	Good

From Table 4, the cover image in Hou's algorithm is grayscale image, the stego image 2 is random lattice,and the recovered image has the problem of pixel expansion (m=4). In case of minor modification, it may be low chromatic aberration between the secret regions and others, so, identifying the secret information through human vision is difficult in this case. This paper's algorithm has no pixel expansion, and all the two stego images are meaningful. All the non-secret information regions of recovered image are formed by black pixels, so the recovered image has better visual effect. Combined with the grey-level modification method in Hou's algorithm, this paper's algorithm can extends to the grayscale stego image algorithm, and the recovered image could also have high visual effect.

5 Conclusions

This paper proposes a visual Hiding method based on visual cryptography. This algorithm chooses the ideal embedding region for secret image based on the HVS characters, which can decrease the possibility of the meaningful neighbor pixels adhesion of the secret image, and decrease the phenomenon of the exposing of the secret. While inversing the cover images, it improves the contrasts of the recovered image.

Abstract. A method of multiplier is presented for solving optimization problems. For large-scale constraint problems, combining the active set strategy, we use the aggregate function to approximate the max-value function. Only a few of functions are involved at each iteration, so the computation for gradient is significantly reduced. The numerical results show that the method is effective.

Introduction

We consider the nonlinear programming problem

$$\min f^0(x)$$
$$\text{s.t. } f^i(x) \le 0, \quad i \in M = \{1, 2, \cdots, m\}, \tag{1}$$

where $f^i(x): R^n \to R$ and m is a very large positive integer. The feasible set set is denoted by Ω. Nonlinear programming has a wide application, such as economic plan, engineering design and optimization control, transportation and national defense and other fields [1,2].

Rather than linear programming has won recognition such as the simplex method and interior-point method, it is of great difficulty and challenge for the solution of the nonlinear optimization, because the problem with large numbers of constraints usually appears in real life situations and constraints can sometimes be quite complicated. Many researchers have long committed to the research of nonlinear optimization algorithm effectively, and has achieved fruitful results.

At present, there are several classes of methods to solve the problem (1), including SQP methods, interior-point methods, the methods of feasible directions and penalty methods, etc. A difficulty is huge amount of calculation due to the large number of constraints to solve the problem (1.1), and active set strategies [3] will be used to deal with the problem in this paper.

The paper is organized as follows. An augmented Lagrangian method for (1) is presented and the details of the algorithm with active set strategy are also given in section 2.

Numerical tests comparing the performance of the proposed method with general augmented Lagrangian method without active set strategy in section 3. Finally, the summary of this paper is made.

Augmented Lagrangian method

We transform (1) into the following form

$$\min f^0(x)$$
$$\text{s.t. } f_{\max}(x) = \max_{i \in M} f^i(x) \le 0. \tag{2}$$

As we know, the aggregate function is a good approximation function of the max value function[4]. For $f_{\max}(x)$ in (2), the aggregate function is defined as

$$f_p(x) = \frac{1}{p}\ln(\sum_{i=1}^{m}\exp(pf^i(x))), \tag{3}$$

where p>0 is referred to as the smoothing parameter[3].

We now consider the approximation of problem (2)

$$\min f^0(x)$$
$$\text{s.t. } f_p(x) \le 0. \tag{4}$$

It can be transformed into the equality constrained problem

$$\min f^0(x)$$
$$\text{s.t. } f_p(x) + y^2 = 0.$$

The corresponding the augmented Lagrange function is as follow,

$$\tilde{\psi}_p(x, y, \lambda, \sigma) = f^0(x) - \lambda[f_p(x) + y^2] + \frac{\sigma}{2}[f_p(x) + y^2]^2.$$

We minimize $\tilde{\psi}_p(x, y, \lambda, \sigma)$ about y. Let

$$\nabla\tilde{\psi}_p(x, y, \lambda, \sigma) = 0,$$

we have

$$y^2 = \begin{cases} \frac{1}{\sigma}[\lambda - \sigma f_p(x)], & \text{if } \lambda - \sigma f_p(x), \\ 0, & \text{else.} \end{cases}$$

So

$$f_p(x) + y^2 = \begin{cases} \frac{1}{\sigma}\lambda, & \text{if } \lambda - \sigma f_p(x), \\ f_p(x), & \text{else.} \end{cases}$$

From the above conditions, the fact is that

$$-\lambda[f_p(x) + y^2] + \frac{\sigma}{2}[f_p(x) + y^2]^2 = \frac{1}{2\sigma}((\min\{0, \lambda - \sigma f_p(x)\})^2 - \lambda^2),$$

so the variable y in $\tilde{\psi}_p(x, y, \lambda, \sigma)$ can be eliminated, we denote it by

$$\tilde{\psi}_p(x, \lambda, \sigma) = f^0(x) + \frac{1}{2\sigma}((\min\{0, \lambda - \sigma f_p(x)\})^2 - \lambda^2).$$

Now we begin by describing an augmented Lagrange method for minimizing the problem.

Algorithm 2.1 (ASAL method)

Initialization. $x^0 \in R^n, p_1, \hat{p}, \sigma_1, \varepsilon(p) > 0, \lambda_1 \in R, \mu, \eta > 1, i = 1.$

Step 1. Let x^{i-1} be the initial point, deriving the minimal point x^i to solve the problem

$$\min\tilde{\psi}_{p_i}(x, \lambda_i, \sigma_i)$$

using subroutine 2.1.

Step 2. If $\|\nabla\tilde{\psi}_{p_i}(x^i, \lambda_i, \sigma_i)\| \le \varepsilon(p_i)$ is not satisfied, go to Step 3. Otherwise, if $p_i > \hat{p},$, stop; else set $p_{i+1} = \mu p_i, x^{i+1} = x^i, i = i+1,$, go to Step 2.

Step 3. If $\|\nabla\tilde{\psi}_{p_i}(x^i, \lambda_i, \sigma_i)\| \ge \|\nabla\tilde{\psi}_{p_i}(x^{i-1}, \lambda_i, \sigma_i)\|$, set $\sigma_{i+1} = \eta\sigma_i;$ else set $\sigma_{i+1} = \sigma_i$.

Step 4. $\lambda_{i+1} = \min\{0, \lambda_i - \sigma_i f_{p_i}(x_i)\}$.

Step 5. Set $p_{i+1} = p_i, i = i+1,$ go to Step 1.

For convenience, we denote $\tilde{\psi}(x) = \tilde{\psi}_{p_i}(x^i, \lambda_i, \sigma_i)$. In addition, we define

$$Q_\varepsilon(x)=\{j\in M \mid f_{\max}(x)-f^i(x)\le\varepsilon\}.$$

Subroutine 2.1 (Solving subproblem)

Initialization. $t=0, x^{i0}=x^{i-1}, \alpha\in(0,1/2), \beta\in(0,1), \bar{\varepsilon}>0, \Omega_0=Q_\varepsilon(x^{i0}), B_0=E.$

Step 1. Compute the search direction d^t by solving the equation

$$B_t d=-\nabla\tilde{\psi}^{\Omega_t}(x^{it})$$

of d.

Step 2. Find the smallest nonnegative integer m_t such that

$$\tilde{\psi}^{\Omega_t}(x^{it}+\beta^{m_t}d^t)-\tilde{\psi}^{\Omega_t}(x^{it})\le\alpha\beta^{m_t}\nabla\tilde{\psi}^{\Omega_t}(x^{it})d^t.$$

Set $\tau_t=\beta^{m_t}$.

Step 3. Set $x^{i,t+1}=x^{it}+\tau_t d^t, \Omega_{t+1}=\Omega_t\cup Q_\varepsilon(x^{i,t+1})$.

Step 4. If $\|\nabla\tilde{\psi}^{\Omega_{t+1}}(x^{i,t+1})\|\le\bar{\varepsilon}$, set $x^i=x^{i,t+1}$, exit. Else, set $t=t+1$, go to Step 1.

Numerical experiment

In this section, compare our method with general augmented Lagrangian method without active set strategy, denoted by AL method.

Parameters in AL/ASAL method and subroutine are set as:

$p_1=100, \hat{p}=10^7, \sigma_1=2, \mu=5, \eta=10, \varepsilon(p)=10^{-6}, \alpha=0.1, \beta=0.5, \bar{\varepsilon}=10^{-6}.$

All the computations are done by running MATLAB2009b. Numerical results are listed in following tables, where x^* is the optimal point, $f(x^*)$ is the optimal value, k denotes the number of outer iterations, ink denotes the number of inner iterations and time is the CPU time in seconds.

Problem 4.1

$$f^0(x)=x_3^2+x_4^2,$$
$$f^{i,j}(x)=(t_i-x_1)^2/x_3^2+(t_j-x_2)^2/x_4^2-1,$$
$$t_i=i/(\sqrt{m}-1), i=1,\cdots,\sqrt{m}-1,$$
$$t_j=j/(\sqrt{m}-1), j=1,\cdots,\sqrt{m}-1,$$
$$x^0=(0,0,100,100).$$

Table 1 The numerical results of Problem 4.1

m	method	x^*	$f(x^*)$	k	ink	time
25	AL	(0.5000,0.5000,-0.7071,-0.7071)	1	7	38	0.3228
	ASAL	(0.5000,0.5000,-0.7071,-0.7071)	1	7	32	0.3754
100	AL	(0.5000,0.5000,-0.7071,-0.7071)	1	7	61	0.3734
	ASAL	(0.5000,0.5000,-0.7071,-0.7071)	1	7	36	0.3675
2500	AL	(0.5000,0.5000,-0.7071,-0.7071)	1	8	68	2.8626
	ASAL	(0.5000,0.5000,-0.7071,-0.7071)	1	8	40	1.0044
10000	AL	(0.5000,0.5000,-0.7071,-0.7071)	1	9	84	7.2491
	ASAL	(0.5000,0.5000,-0.7071,-0.7071)	1	9	46	3.2938
250000	AL	(0.5000,0.5000,-0.7071,-0.7071)	1	15	102	257.6934
	ASAL	(0.5000,0.5000,-0.7071,-0.7071)	1	14	73	122.2605

From the above table, we can see that our proposed method, ASAL method, is more effective than the general augmented Lagrange method, especially for multi-constraint problems, our method can save at least half of the time than the traditional one.

Summary

An augmented Lagrangian method is presented in this paper. Due to active-set strategy is involved, at each iteration, only a small subset of components in max value function is aggregated, hence the calculation of gradient is dramatically reduced, so that cost is greatly reduced. Numerical test show that our method is effective.

Consensus Equilibrium Point Analysis for Heterogeneous Multi-agent system in Undirected graph

Sun Yi-Jie Zhang Guo-liang Zeng Jing

High-Tech Institute of Xi'an, Xi'an Shanxi 710025, China

syjlxh@126.com

Keywords: Heterogeneous Multi-agent system, Graph Theory, Equilibrium Point .

Abstract: The consensus problem of heterogeneous multi-agent systems is investigated. A linear consensus protocol is proposed for this system. Aiming at consensus condition can be only obtained, but the consensus equilibrium point cannot be obtained in this study, the consensus equilibrium point is derived by applying graph theory and matrix theory in this paper. Finally, a numerical simulation is provided to illustrate the effectiveness of the theoretical result.

1. Introduction

Recently, decentralized coordination of multi-agent systems has received compelling attention from various scientific communities. For multi-agent systems, a critical problem is to design a distributed control protocol based on local information that makes all agents to reach an agreement on certain global criteria of common interest by negotiating with their neighbors, which is called as the consensus problem. Much progress has been achieved in the study of constructing conditions for reaching consensus among multi-agent systems [1-4].

Unfortunately, all the aforementioned multi-agent systems were homogeneous, that is, all the agents have the same dynamics behavior. However, the dynamics of the agents are quite different because of various restrictions or the common goals with mixed agents in the practical systems. Liu [5] studied the stationary consensus of discrete-time heterogeneous multi-agent systems with communication delays. Yu-Ping Tian studies the high-order consensus problem for heterogeneous multi-agent systems with unknown communication delays [6]. Yuanshi Zheng studies the finite-time consensus problem of heterogeneous multi-agent systems composed of first-order and second-order integrator agents [7].

However, many study on this topic is only consider the consensus condition, the consensus equilibrium point is analyzed rarely, so this paper investigates this problem.

2. Preliminaries

2.1 Graph theory

Let $\mathcal{G}(\mathcal{V},\mathcal{E},\mathcal{A})$ be a weighted directed graph composed of a set of nodes $\mathcal{V}=\{v_1,v_2,...v_n\}$, set of edges $\mathcal{E}\subset\mathcal{V}\times\mathcal{V}$, and a weighted adjacency matrix $A=[a_{ij}]_{n\times n}$, with nonnegative adjacency elements a_{ij} .An edge of $\mathcal{G}$ is denoted by $e_{ij}=(v_i,v_j)\in\mathcal{E}$ .which means that node v_i receives information from node v_j , and v_j is called the parent of v_i .The adjacency elements associated with the edges of the graph are positive i.e., $e_{ij}\in\mathcal{E}\Leftrightarrow a_{ij}>0$. Moreover, we assume $a_{ii}=0$ for all $i\in 1,...n$. The set of neighbors of node v_i is denoted by $N_i=\{v_j\in\mathcal{V}:(v_i,v_j)\in\mathcal{E}\}$ .The corresponding graph Laplacian $L=[l_{ij}]_{n\times n}$ can be defined as:

$l_{ij}=\begin{cases}-a_{ij}, j\neq i\\ \sum_{j\in N_i}a_{ij} \quad j=i\end{cases}$ If $a_{ij}=a_{ji}$, then $\mathcal{G}$ becomes the undirected graph. If there is not isolated node in an undirected graph, the graph is said to be connected.

In heterogeneous multi-agent system, the neighbor of each second-order agent i incudes first-order and second-order agent, denote as $N_i=N_i^s\cup N_i^f$, the neighbor of each second-order denote as $N_l=N_l^s\cup N_l^f$.

The Laplacian matrix can denote as follow: $L=\begin{bmatrix} \bar{L}_s & -A_{sf} \\ -A_{fs} & \bar{L}_f \end{bmatrix}$,

where, $\bar{L}_s = D_{sf} + L_s$, L_s is the Laplacian matrix of second-order agent, $D_{sf} = diag(\sum_{j\in N_i^f} a_{ij}, i = 1,....m)$, denotes the adjacency relations of second-order agent to first-order agent. Meanwhile, L_f is the Laplacian matrix of first-order agent, $D_{fs} = diag(\sum_{j\in N_l^s} a_{lj}, l = m+1,....n)$, A_{fs} denotes the adjacency relations of second-order agent to first-order agent.

2.2 The heterogeneous multi-agent system

Suppose that the heterogeneous multi-agent system consists of first-order and second-order integrator agents. The number of agents is n, labeled 1 through n.Firstly, the heterogeneous multi-agent system and concept of consensus are established. Suppose that the number of second-order integrator agents is $m(m<n)$.The remainder is first-order integrator agents, the number is $n-m$.Then the system is given as follows:

$$\begin{cases} \dot{x}_i = v_i \\ \dot{v}_i = u_i \qquad i = 1,...m \\ \dot{x}_l = u_l \qquad l = m+1,....n \end{cases} \tag{1}$$

Where x_i, v_i, u_i are the position, velocity and control input, of second-order agent i respectively. x_l, u_l are the position and control input of first-order agent l respectively. The initial conditions are $\boldsymbol{x}(0) = [x_1(0), x_2(0),...x_n(0)]^{\mathrm{T}}$, $\boldsymbol{v}(0) = [v_1(0), v_2(0),...v_m(0)]^{\mathrm{T}}$.

3. Main results

In this section, we first propose the consensus protocol for the heterogeneous multi-agent system (1) as follows

$$\begin{cases} u_i = k_1 \sum_{j\in N_i} a_{ij}(x_j - x_i) + k_2 \sum_{j\in N_i^f} a_{ij}(v_j - v_i), i = 1,...m \\ u_l = k_3 \sum_{j\in N_l} a_{ij}(x_j - x_i), l = m+1,...n \end{cases} \tag{2}$$

Where, $k_1, k_2, k_3 > 0$ are the control gains. Let $\boldsymbol{y} = [x_s^{\mathrm{T}}, v_s^{\mathrm{T}}, x_f^{\mathrm{T}}]^{\mathrm{T}}$, the system can be denote following matrix form

$$\dot{y} = \Gamma y = \begin{bmatrix} 0 & I_m & 0 \\ -k_1\bar{L}_s & -k_2 L_s & k_1 A_{sf} \\ k_3 A_{fs} & 0 & -k_3\bar{L}_f \end{bmatrix} y \tag{3}$$

Lemma 1[3] Let $\mathcal{G}(\mathcal{V},\mathcal{E},\mathcal{A})$ be a undirected graph with Laplacian L . If $\mathcal{G}(\mathcal{V},\mathcal{E},\mathcal{A})$ is connected, then, $rank(L) = n-1$.

Theorem 1 The sufficient condition of the heterogeneous multi-agent system (1) achieves consensus with protocol (2) is as follow

(1)The $\mathcal{G}(\mathcal{V},\mathcal{E},\mathcal{A})$ is connected, and the subgraph $\mathcal{G}^s(\mathcal{V},\mathcal{E},\mathcal{A})$ of $\mathcal{G}(\mathcal{V},\mathcal{E},\mathcal{A})$, which includes all second-order agent is also connected;

(2)The parameters satisfy following conditions: $0 < k_1 < k_2 \min d_i^s - \max d_i, k_2 > \max d_i / \min d_i^s, k_3 > 0$.

Where, $d_i^s, i = 1,...m$ is the diagonal element of L_s , and $d_i, i = 1,...m$ is the diagonal element of L.

Proof: Consensus of the system(3) depends on the eigenvalues of matrix Γ. A nonsingular transformation P is introduced for analyzing matrix Γ.

$$P = \begin{bmatrix} I & 0 & 0 \\ I & \dfrac{I}{k_1} & 0 \\ 0 & 0 & I \end{bmatrix}, \quad \bar{\Gamma} = P\Gamma P^{-1} = \begin{bmatrix} -k_1 I & k_1 I & 0 \\ -\bar{L}_s + k_2 L_s - k_1 I & k_1 I - k_2 L_s & A_{sf} \\ k_3 A_{fs} & 0 & -k_3\bar{L}_f \end{bmatrix}.$$

The matrix Γ and $\bar{\Gamma}$ has identical eigenvalues owing to P is nonsingular.When condition (1), (2) are satisfied, it can be verified that $\bar{\Gamma}$ is a Laplacian matrix of a network which contains $n+m$ agents. The row and column transform are imposed on matrix $\bar{\Gamma}$, then the below form can be derived.

$$\tilde{\Gamma} \to \begin{bmatrix} -I_m & 0 & 0 \\ 0 & \bar{L}_s & A_{sf} \\ 0 & k_3 A_{fs} & -k_3 \bar{L}_f \end{bmatrix} \to \begin{bmatrix} I_m & 0 & 0 \\ 0 & \bar{L}_s & -A_{sf} \\ 0 & -A_{fs} & \bar{L}_f \end{bmatrix}$$

Obviously, $rank(\bar{\Gamma}) = m + rank(L)$. Based on lemma 1, we have $rank(L) = n-1$, $rank(\bar{\Gamma}) = n+m-1$ .Then, matrix $\bar{\Gamma}$ only has a simple zero eigenvalue, and the other eigenvalues all have negative real part. Meanwhile, matrix Γ has identical eigenvalue property. Γ has a simple zero eigenvalue with an associated eigenvector $w_1 = [1_m^{\mathrm{T}}, 0_m^{\mathrm{T}}, 1_{n-m}^{\mathrm{T}}]^{\mathrm{T}}$.

The solution of system (3) can be denoted as follow $\lim_{t\to\infty} y(t) = e^{\Gamma t} y(0)$ .We have $e^{-\Gamma t} = Q \begin{bmatrix} 1 & 0 \\ 0 & e^{J} \end{bmatrix} Q^{-1}$,

where Q is a nonsingular transformation, and J is the Jordan block associated non-zero eigenvalue of matrix Γ .Due to the other eigenvalues all have negative real part , then $\lim_{t\to\infty} e^{-J} = \mathbf{0}_{(n+m-1)\times(n+m-1)}$.

Then, $$\lim_{t\to\infty} y(t) = e^{\Gamma t} y(0) = w_1 v_1^{\mathrm{T}} y(0) = \begin{bmatrix} \mathbf{1}_m v_1^{\mathrm{T}} \boldsymbol{y}(0) \\ \mathbf{0}_m \\ \mathbf{1}_{n-m} v_1^{\mathrm{T}} \boldsymbol{y}(0) \end{bmatrix}$$

$w_1 = [1_m^{\mathrm{T}}, 0_m^{\mathrm{T}}, 1_{n-m}^{\mathrm{T}}]^{\mathrm{T}}$, v_1^{T} is the left eigenvector associated eigenvalue zero, and $v_1^{\mathrm{T}} w_1 = 1$ .It can be seen that the convergence value of system satisfy the requirement of definition 1.

Remark 2: There is a $d_i \neq 0$ at least owing to the graph is undirected connected. The subgraph $\mathcal{G}^s(\mathcal{V}, \mathcal{E}, \mathcal{A})$ of $\mathcal{G}(\mathcal{V}, \mathcal{E}, \mathcal{A})$ which contains all second-order agents is also connected, then all $d_i^s \neq 0$, thus condition (1) can be satisfied.

Theorem 2 If the conditions of theorem 1 are satisfied, the consensus equilibrium point of system (3) is as follow

$$\lim_{t\to\infty} x_i(t) \to \frac{k_3 \sum_{i=1}^{m} v_i(0) + k_1 \sum_{l=m+1}^{n} x_l(0)}{k_1 (n-m)}, i = 1, \ldots n \tag{4}$$

$$\lim_{t\to\infty} v_i(t) \to 0, i = 1, \ldots m$$

Proof: It is easy to verify that the zero eigenvalue of matrix with an associated eigenvector and left eigenvector are $\boldsymbol{w}_1 = [\mathbf{1}_m^{\mathrm{T}}, \mathbf{0}_m^{\mathrm{T}}, \mathbf{1}_{n-m}^{\mathrm{T}}]^{\mathrm{T}}$ and $\boldsymbol{v}_1^{\mathrm{T}} = [\mathbf{0}_m^{\mathrm{T}}, \alpha k_3 \mathbf{1}_m^{\mathrm{T}}, \alpha k_1 \mathbf{1}_{n-m}^{\mathrm{T}}]$ respectively, and $v_1^{\mathrm{T}} w_1 = 1$ for $Q^{-1} Q = I$ .Then, we have $\alpha = 1/[k_1(n-m)]$. According to theorem1, $\lim_{t\to\infty} y(t) = w_1 v_1^{\mathrm{T}} y(0) = \begin{bmatrix} \mathbf{1}_m v_1^{\mathrm{T}} y(0) \\ \mathbf{0}_m \\ \mathbf{1}_m v_1^{\mathrm{T}} y(0) \end{bmatrix}$ .Then , $\lim_{t\to\infty} x_i(t) \to v_1^{\mathrm{T}} y(0) = \frac{k_3 \sum_{i=1}^{m} v_i(0) + k_1 \sum_{l=m+1}^{n} x_l(0)}{k_1 (n-m)}$, $\lim_{t\to\infty} v_i(t) \to 0, i = 1, \ldots m$.

4. Simulation

In this section, a numerical simulation is provided to illustrate the effectiveness of the theoretical result in Section 3. Consider a heterogeneous multi-agent system with 4 agents shown in Fig. 1, where node 1, 2 are second-order agent, and node 3, 4 are first-order agents. The graph is undirected connected .If $e_{ji} \in \mathcal{E}$, then $a_{ij} = 1$, else $a_{ij} = 0$.

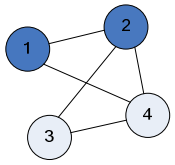

Fig. 1. Interconnection graph.

According to the conditions in theorem1, we select $k_1 = 1.4$, $k_2 = 4.5$, $k_3 = 1.2$, The initial condition are $\boldsymbol{x}(0) = [2, 1, 2.5, 1.5]^{\mathrm{T}}$, $v(0) = [1, 2]^{\mathrm{T}}$ .Based on (4), we have .

The simulation results (Fig. 2 and Fig. 3) show that the positions of all agents and the velocities of second -order agents achieve consensus asymptotically.

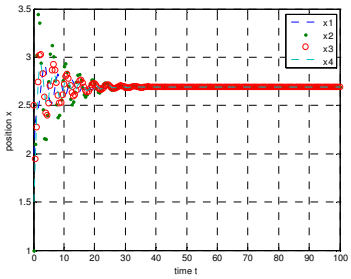

Fig. 2 Position of all agents

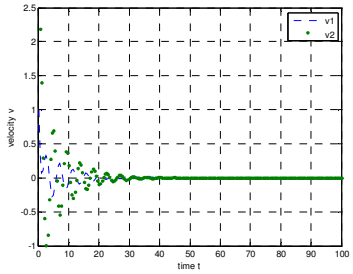

Fig3. Velocity of second-order agents

When the system (3)satisfy condition(1), (2) in theorem 1, it can be seen that velocity of all second-order agents converge to zero, and position of all agents converge to consensus equilibrium point(4). The result illustrates the effectiveness of the theoretical result.

5. Conclusion

This paper investigates the consensus problem of heterogeneous multi-agent system which includes first -order and second-order agents. Consensus equilibrium point of the system is derived in undirected graph based on graph theory and matrix theory. Finally, a numerical simulation is provided to illustrate the effectiveness of the theoretical result. This paper only considers undirected graph, in following work digraph will be considered.

A Projected Conjugate Gradient Method for Box-Constrained Optimization

Tingfeng LI, Zhiyuan LIU and Zhaobin DU

Zhengzhou Technical College, Zhengzhou 450121,China

tingfengli@126.com

Keywords: unconstrained optimization, conjugate gradient method, box-constrained program.

Abstract. In this paper, we introduce an algorithm for solving large-scale box-constrained optimization problems. At each iteration of the proposed algorithm, we first estimate the active set by means of an active set identification technique. The components of the search direction corresponding to the active set are simply defined; the other components are determined by nonlinear conjugate gradient method. Under some additional conditions, we show that the algorithm converges globally. We also report some preliminary numerical experiments to show that the proposed algorithm is practicable and effective for the test problems.

Introduction

In this paper, we propose a projected conjugate gradient method for solving the following box-constrained optimization problem.

$$\min_{x\in \mathrm{R}^n} f(x) \tag{1}$$

where $f:\mathrm{R}^n \to \mathrm{R}$ is continuously differentiable, and $l,u\in \mathrm{R}^n$ with $l<u$. We denote the gradient of f at x by $\nabla f=\left(\nabla f_1(x),...,\nabla f_n(x)\right)$, and define the feasible region of (1) by Ω be, i.e.,

$$\Omega=\left\{x\in \mathrm{R}^n : l\le x\le u\right\} \tag{2}$$

We say that a vector $\bar{x}\in\Omega$ is a stationary point for problem (1) if it satisfies

$$\begin{cases} l_i=\bar{x}_i & \Rightarrow \nabla f_i(\bar{x})\ge 0 \\ l_i<\bar{x}<u_i & \Rightarrow \nabla f_i(\bar{x})=0 \\ \bar{x}_i=u_i & \Rightarrow \nabla f_i(\bar{x})\le 0 \end{cases} \tag{3}$$

Strict complementarily is said to hold at $\bar{x}$ if the strict inequalities hold in the first and the last implications of (3).

Many algorithms for solving this type of problems are based on active set strategies (see [2, 7, 8, 13]). In this class of methods a working set estimates the set of active constraints at the solution and it is updated from iteration to iteration. The early active set methods are quite efficient for relatively lower dimensional problems, but are typically unattractive for large-scale problems (see [1, 6]).The main reason is that at most one constraint can be added to or dropped from the active set at each iteration, and this slow down the rate of the convergence. Because of it, it explodes more and more scholars to study the design of active set methods so as to be capable of making rapid changes to incorrect predictions (e.g. [2, 3, 7, 8]).

The gradient projection method is (e.g. [1])a effective method in identifying the active set. They have the advantage that many constraints can be added to or dropped from the active set at each step. The gradient projection technique has been further studied for solving nonlinear optimization problems, both for general linearly constrained case and for the bound constrained case(see [3, 4, 5, 11, 12, 14]). The bound constrained optimization problems have received much attention in recent decades, we refer to (see[9, 10]) for good reviews.

The paper is organized as follows. We first propose the construction of our new algorithm in the next section. In section 3, we establish the global convergence of the new method. In section 4, we test the

performance of the proposed algorithm and compare it with the other well known methods. Throughout the paper, the symbol $\|\bullet\|$ denotes the Euclidean norm of vectors.

Motivation and Algorithm

In this section we first recall the active set estimation technique in [14], then we present our new algorithm based on a modified PRP conjugate gradient method. The following two assumptions are important to our algorithm.

Assumption 2.1. *The level set* $\Re = \left\{x \in \mathrm{R}^n : f\left(x\right) \le f\left(x^0\right)\right\} \cap \Omega$ *is compact.*

Assumption 2.1. *In some neighborhood of* $\Re$*, the gradient* $g(x)$ *is Lipschitz continuous, i.e., there exists a constant* $L > 0$ *such that* $\left\|g\left(x\right) - g\left(y\right)\right\| \le L\left\|x - y\right\|, \forall x, y \in \Re$.

Now, we state the active set identification technique in [14], and describe how to construct a search direction subsequently. Let $a_i\left(x\right)$ and $b_i\left(x\right)$ be nonnegative continuous and bounded function defined on Ω , such that if $x_i = l_i$ or $x_i = u_i$ then $a_i\left(x\right) > 0$ or $b_i\left(x\right) > 0$, respectively. For any $x \in \Omega$ we can define the index sets $L(x)$, $F(x)$ and $U(x)$ as follows

$$\begin{cases} L\left(x\right) = \left\{i : x_i \le l_i + a_i\left(x\right)\nabla f_i\left(x\right)\right\} \\ U\left(x\right) = \left\{i : x_i \ge u_i + b_i\left(x\right)\nabla f_i\left(x\right)\right\} \\ F\left(x\right) = \left\{1,...,n\right\} \setminus \left(L \cup U\right) \end{cases} \tag{4}$$

The set $L(x) \bigcup U(x)$ is an estimate of the active set at point x. F. Facchinei, J. Judice and J. Soares (see [14]) showed that if the strict complementary condition holds at $\overline{x}$, then when x is sufficiently close to $\overline{x}$, the index sets $L(x) \bigcup U(x)$ is an exact identification of $L(\overline{x}) \bigcup U(\overline{x})$. This property will enable us to find the active sets at the stationary point $\overline{x}$ in a finite number of steps.

By using the active set estimate, we deduce the search direction used in our algorithm. Details will be given subsequently. For the sake of simplicity, we let $L^k = L\left(x^k\right), U^k = U\left(x^k\right), F^k = F\left(x^k\right)$, and $\left|F^k\right|$ be the number of elements in F^k. Let $d^k = \left(d^k_{L^k}, d^k_{F^k}, d^k_{U^k}\right)$ in which d^k_L and d^k_U is determined by

$$d^k_i = l_i - x^k_i, i \in L^k \tag{5}$$

$$d^k_i = u_i - x^k_i, i \in U^k \tag{6}$$

Let $P_\Omega\left(x\right)$ be the projection on Ω ; Z_k be the matrix whose columns are $\left\{e_i \middle| i \in F^k\right\}$, where e_i is the i-th column of the identity matrix. Let $P_\Omega\left[\bullet\right]$ denotes the projection on Ω , that is

$$P_\Omega\left[x\right] = \begin{cases} x_i & \text{if } l_i \le x_i \le u_i \\ l_i & \text{if } x_i < l_i \\ u_i & \text{if } x_i > u_i \end{cases} \tag{7}$$

The search direction d^k is defined by

$$d^k_i = \begin{cases} l_i - x^k_i, i \in L^k \\ u_i - x^k_i, i \in U^k \\ \left(Z_k \overline{d}^k\right)_i, i \in F^k \end{cases} \tag{8}$$

where $\overline{d}^k$ denotes the search direction of inactive variables, which is determined by the form

$$\overline{d}_k = \begin{cases} -\overline{g}^0 & k = 0 \\ -\overline{g}^k + \beta_k \overline{d}^{k-1} - \theta_k \overline{y}^{k-1} & k > 0 \end{cases} \tag{9}$$

Where $\beta_k = \frac{\left(\bar{g}^k\right)^T \bar{y}^{k-1}}{\left\|\gamma_{k-1}\right\|^2}$ and $\theta_k = \frac{\left(\bar{g}^k\right)^T \bar{d}^{k-1}}{\left\|\gamma_{k-1}\right\|^2}$, where $\bar{g}^k = Z_k^T g^k$, $\bar{y}^{k-1} = \bar{g}^k - \bar{g}^{k-1}$, and $\gamma_k = P_\Omega\left(x^k - g^k\right) - x^k$.

The result is obvious, hence we omit the proof here. Whenever $d^k \neq 0$, it is at least a descent direction for objective function f at current point x^k, and the property is very important for us to establish the global convergence. Now we can describe the algorithm for solving the bound constrained optimization problems (1) as follows:

Algorithm 2.1.

Step 0. Given starting point $x_0 \in \Omega$, constants $\delta \in (0,1/2)$. Set $k = 0$.

Step 1. Determine $L^k = L\left(x^k\right)$, $U^k = U\left(x^k\right)$, $F^k = F\left(x^k\right)$ according to (8).

Step 2. Compute d^k by (9). If $d^k = 0$ then stop.

Step 3. Set $x_{k+1} = P_\Omega\left(x_k + \alpha_k d_k\right)$, α_k attained by the projected Armijo line search, and update d^k to get d^{k+1} by (5).

Step 4. Set $k := k+1$. Go to Step 1.

Numerical Experiments

In this section, we analyze the feasibility and effectiveness of the Algorithm 2.1 (named PCGM). The algorithm is implemented by Fortran95 code in double precision arithmetic. All runs are performed on a PC (Intel Pentium(R) 4, 2.8 GHz, 2G DDR3) with Red Hat 9.03 Linux OS. Our experiments are performed on a subset of the nonlinear unconstrained problems from CUTEr[12] library, and the second-order derivatives of all the selected problems are available. Since we are interested in large problems, we only considered problems with dimensions at least 100. The algorithm stops if the norm of the final gradient is less than 10^{-5}, that is, $\left\|\nabla f\left(x\right)\right\| \le 10^{-5}$.

For this Method, we set the initial matrix $\mathrm{H}_0 = \gamma I$, I is an identity matrix. In this experiment, we take $\mu = 0$, $\overline{C} = 10^{-7}$, $\sigma_1 = 10^{-4}$, $\sigma_2 = 0.9$, $m = 6$, $n = 100$, to test the behavior of the PCGM with different values $\overline{C}$. The numerical results are listed in following Table, which contains the name of each problem, the number of iterations (Iter), the number of function evaluations (NF), the CPU time required in seconds (Time). Symbol "-" indicates method stops without meeting the stopping criteria. Through the Table, we see that the values of $\overline{C}$ slightly affect the numerical behavior of PCGM. Moreover, it seems that $\overline{C} = 10^{-7}$ and $\overline{C} = 10^{-9}$ yields better performance than the remaining.

Table Numerical Results with Different $\overline{C}$

	$\overline{C}=10^{-2}$			$\overline{C}=10^{-5}$			$\overline{C}=10^{-7}$			$\overline{C}=10^{-9}$

Summary

We proposed a PCGM method with Armijo line-search for solving Box-Constrained optimization problems. The results showed that the choice of parameters affected the performance of the method. Moreover, if we choose them appropriately, the numerical behavior can be highly improved. The next research will be compared the PCGM and the other algorithms.

Keywords: Quota decomposition in rural land; New Construction Land; Analytic hierarchy process (AHP）

Abstract. This article take LuoCheng MuLao Nationality Autonomous County in Guangxi province as a sample, decomposing the new construction land quota in this county based on AHP in determining the quota decomposition weights. In addition, this paper selected rural fixed assets investment, urban population, the total construction land during planning and implementation period, gross domestic product, four factors as the significant influencing ones. And standardized treatment of these factors to the indicators' vector set.

Introduction

The focus of the general land use planning in our country is to determine and adjust the land use structure and layout the limited land resources in the production and living for scientific and reasonable configuration .New construction land quota decomposition is the key and difficult point for a new round of general land use planning .Scientific and reasonable decomposition of new construction land quota ,to promote economic and social coordinated development plays an important role .About the township general land use planning of newly-increased construction land at the bottom in the general land use planning in our country .The quota distribution of appropriateness is directly related to the superior the implementation of general land use planning and implementation [1].

The quota decomposition method

Analytic hierarchy process (AHP).The Analytic Hierarchy Process is to build a multi-layered analysis of the structural model, in the hierarchy of the decision problem in the large system[2]. Select the factor determining, standardized indicators of the township township drawn vector set A, analytic hierarchy process to determine the right to select the factor weights in the quota system B, Finally it is concluded that the township administrative domain decomposition quota were weighted C [3].

Township quota vector set (A). Select 2010 Guangxi Luocheng County non-agricultural population, 2010 urban GDP, 2010 investment in fixed assets, construction land in 2020 predicted four data as a factor ,As shown in table 1 .To standardize the raw data in table 1,to derive a normalized value, for the standardization of formula:

$$Y_{ki} = \frac{c_{ki} - c_{\min}}{c_{ki} - c_{\min}} . \quad (3)$$

Formula: Y_{ki} is the equivalent value of village K's factor i, c_{ki} is the original value of village K's factor i, $c_{\max}$ is the biggest original value of every village's factor i, $c_{\min}$ is the smallest original value of every village's factor I [4].

Table 1 Standardized indicators

Town name	Construction land	Non-agricultural population	GDP	Fixed assets investment
Longan	0.5267	0.1941	0.4100	0.0261
Huangjin	0.1481	0.0618	0.0566	0.0011
Baotan	0.1992	0.0515	0.1775	0.3108
Xiao Chang'an	0.4496	0.0456	0.0550	0.0261
Dongmen	1.0000	1.0000	1.0000	1.0000
Siba	0.5154	0.1250	0.1300	0.1570
Tianhe	0.1429	0.0221	0.0343	0.0975
Qiaoshan	0.0759	0.0000	0.0363	0.0573
Naweng	0.0000	0.0000	0.0000	0.0238
Huaiqun	0.1378	0.0147	0.0297	0.0642
Jian'ai	0.0614	0.0000	0.0015	0.0000

To standardize summary four data quota vector set A:

$$A=\begin{bmatrix} 0.5267 & 0.1941 & 0.4100 & 0.0261 \\ 0.1481 & 0.0618 & 0.0566 & 0.0011 \\ 0.1992 & 0.0515 & 0.1775 & 0.3108 \\ 0.4496 & 0.0456 & 0.0550 & 0.0261 \\ 1.0000 & 1.0000 & 1.0000 & 1.0000 \\ 0.5154 & 0.1250 & 0.1300 & 0.1570 \\ 0.1429 & 0.0221 & 0.0343 & 0.0975 \\ 0.0759 & 0.0000 & 0.0363 & 0.0573 \\ 0.0000 & 0.0000 & 0.0000 & 0.0238 \\ 0.1378 & 0.0147 & 0.0297 & 0.0642 \\ 0.0614 & 0.0000 & 0.0015 & 0.0000 \end{bmatrix}$$

The factor weights (B). According to table 1 to compare any two factors, according to the actual situation of the county and economic development trends, get discriminant matrix is shown in Table 2.

Table 2 Construction land affected townships judgment matrix

	Construction land	Non-agricultural population	GDP	Fixed assets investment
Construction land	1	1/7	1/5	1/3
Non-agricultural population	7	1	3	5
GDP	5	1/3	1	3
Fixed assets investment	3	1/5	1/3	1

Calculate the factors weight judgment matrix which factor weight vector B:

$$B=\begin{bmatrix}0.0553\\0.5650\\0.2622\\0.1175\end{bmatrix}$$ calculate the eigenvalues of the matrix A maximum λ_{max}=4.1170, Through the consistency check, $CI=\frac{\lambda_{max}-n}{n-1}$ =0.039，n=4；Look-up table shows RI=0.90.So $CR=\frac{CI}{RI}$ = 0.0433＜0.1，The consistency of the matrix is satisfied can use.

Quota decomposition weight vector. According to the formula (1) the new construction land quota decomposition weight vector is: C=A×B

$$C=\begin{bmatrix}0.5267 & 0.1941 & 0.4100 & 0.0261\\0.1481 & 0.0618 & 0.0566 & 0.0011\\0.1992 & 0.0515 & 0.1775 & 0.3108\\0.4496 & 0.0456 & 0.0550 & 0.0261\\1.0000 & 1.0000 & 1.0000 & 1.0000\\0.5154 & 0.1250 & 0.1300 & 0.1570\\0.1429 & 0.0221 & 0.0343 & 0.0975\\0.0759 & 0.0000 & 0.0363 & 0.0573\\0.0000 & 0.0000 & 0.0000 & 0.0238\\0.1378 & 0.0147 & 0.0297 & 0.0642\\0.0614 & 0.0000 & 0.0015 & 0.0000\end{bmatrix}\times\begin{bmatrix}0.0553\\0.5650\\0.2622\\0.1175\end{bmatrix}=\begin{bmatrix}0.2494\\0.0581\\0.1232\\0.0681\\1.0000\\0.1517\\0.0408\\0.0204\\0.0028\\0.0313\\0.0038\end{bmatrix}$$

Table 3 New construction land quota decomposition of LuoCheng county in 2005-2020

Town name	Weight vector	Weights（%）	New construction land（hm）
Longan	0.2494	14.25%	153.84
Huangjin	0.0581	3.32%	35.84
Baotan	0.1232	7.04%	75.99
Xiao Chang'an	0.0681	3.89%	42.01
Dongmen	1.0000	57.16%	616.83
Siba	0.1517	8.67%	93.57
Tianhe	0.0408	2.33%	25.17
Qiaoshan	0.0204	1.17%	12.58
Naweng	0.0028	0.16%	1.73
Huaiqun	0.0313	1.79%	19.31
Jian'ai	0.0038	0.22%	2.34

Conclusion

New construction land quota decomposition embodies fully long-term requirements of social development and government function. To respect the economic development and land resources allocation rule [5].According to the research, with economic growth theory, the configuration elements equilibrium theory and resource cost theory established on the basis of the theoretical system more suitable for the current China's land management actual needs , the result of land use planning and related policy design has reference value .But as a result of land use exist obvious difference in different areas, there isn't a decomposition method is completely general applicability. So we should breakthrough the shackles of traditional planning ideas, in the latest research progress

based on the theory, build and use more advanced and reliable analytical methods and tools of land resources, promote the rational exploitation and protection of land resources [6]. The author considered AHP into new construction land quota decomposition, results considering land economic laws, perhaps it has a certain gap with the county government target -coordinated development, so how to improve the configuration and coordination of economic law the land still has a long way to go.

Abstract. According to the trend of the development of the computer system bus more, designs the general high-speed data storage system based on computer platform structure.Put forward the "one-way chain" cache structure, to avoid the computer operating system of real-time data transmission, the influence of the multithreaded mode data transmission and storage of parallel processing.According to the basic principle of data storage in a computer system, put forward the standard file operations function replace special instruction set, the method of implementing the SCSI disk array storage at a high speed.Test results show that the data storage system based on computer platform with more generalization method to achieve the high speed of data storage.

Introduction

With the rapid development of computer technology, computer system structure, bus transmission mode, operating system, real-time and stability has a larger increase, general platform for the realization of the high speed data storage provided the necessary hardware platform and software environment.[1-4] Below according to the current computer system structure and its development trend, the basic structure of generalized high-speed data storage system design, and on the high speed data transmission and storage technology research, generalization method based on computer platform is put forward.

1 The system structure design

The computer's basic composition structure as shown in figure 1.Only a PCI bus system, most of the peripheral equipment through PCI bus, the occurrence of the (South Bridge) and North (North Bridge) chip connection.

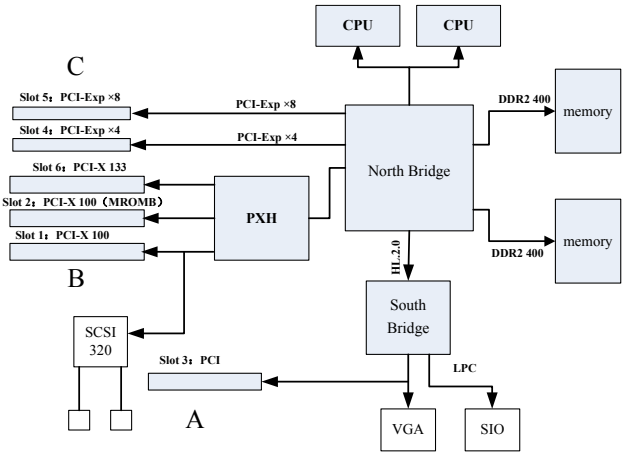

Fig1 Intel 7520 computing system structure

With the rapid development of computer technology, the structure of the computer system on the basis of the original large changes have taken place, the main difference is adopted multibus structure, in addition to basic PCI bus in a computer system also provides a PCI-X and PCI-E two high-speed bus.

PCI - X bus by IBM and guide, it belongs to the expansion of the PCI bus architecture, compared with PCI bus, PCI-X can automatically remove without data exchange PCI-X devices, in order to reduce the waiting for the bus cycle, therefore, under the same frequency PCI-X performance will

be 14%~35% higher than that of PCI. PCI-version 2.0 X can currently support 66 MHZ, 100 MHZ, 133 MHZ this three kinds of frequency, in turn, can manage 4, 2, 1 PCI-X devices, and with 533 MB/s respectively, and 800 MB/s, and 800 MB/s peak bandwidth.

PCI and PCI-X bus is USES the work pattern of time-sharing multiplexing, this also limits the further increase of transmission speed. In 2001, Intel introduced the PCI Express bus (PCI-E).With all PCI devices share the same bus resources, PCI-E bus USES peer-to-peer technology, can be exclusive to each equipment distribution channels, this fully guarantee the bandwidth of each equipment to improve data transmission rate. On the data transfer mode, PCI-E bus adopt unique dual channel transmission model, similar full duplex work mode, send and receive data synchronization, greatly improve the speed of data transmission. At present, the latest PCI-E x 16 standard bus transmission speed (two-way bandwidth) 8 GB/s.[5]

Chipset Intel 7520 to build a computer system as an example, it provides 1 the PCI bus, article 3 of the PCI bus and 2 X PCI-E bus, the structure is shown in figure 2.1 the PCI bus connection in the occurrence of the chip, 2 PCI-E bus directly with "north" chip connection, 3 - through PCI bus X PC-X I controller (PXH) connected to the "north". The distribution characteristics of multibus, provides high speed data transmission and storage with independent channels, overcomes the traditional computer structure on the properties of high speed data storage limit.

At 7520 chipset Intel build computer system structure as reference, design the basic structure of high-speed storage system. Currently used data acquisition card of PCI bus interface, disk array card PCI - X bus interface. This case, you can connect the data acquisition card and the disk array card in the PCI (figure 2 A) and PCI-X (figure 2 B) bus.[6] Although the two bus are used the time-sharing multiplexing transmission mode, but the data input and storage USES is independent of the transmission channel, so it can give full play of bus transmission performance, to avoid the data transmission performance bottlenecks, improve the stability of the system work.

The whole process of data are shown in figure 2 below. First acquisition card through PCI bus to transmit data to the computer memory, and then the data in the memory under the control of the software after connection in north bridge PCI - X bus, stored in the SCSI RAID disk array. The entire process under control in the computer operating system and application software, through the multithreaded programming model, data acquisition, transmission and storage of parallel processing.

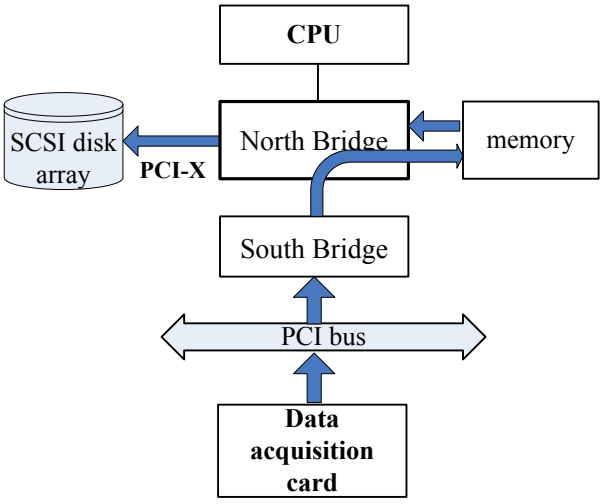

Fig2 Storage system based on computer data process

2 The data transfer

After the acquisition card to collect data through the computer PCI bus in DMA way, continue to transfer to the computer memory, and then to store data in memory to disk. In order to match between DMA and data save data read and write speed difference, realizes the data transmission and storage of parallel processing, usually adopt way temporary serial input data in cache. Computer operating system in order to avoid the non real-time influence on continuous data

acquisition and storage, in addition to adopt the method of optimization of the real-time operating system, can use a "one-way circulation chain" cache structure. As shown in figure 3, it is in the computer memory for several capacity equal to the buffer, in each cache capacity is equal to the amount of data for each DMA transfers. In the process of data transmission and storage, must follow the established order, and in turn cycle for each buffer for data write and read operations.

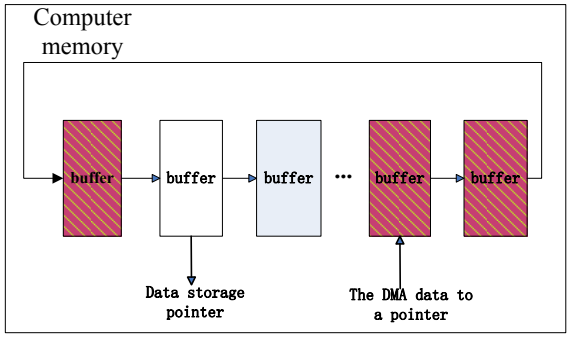

Fig3 One-way circulation chain structure of cache

3 Data storage

The physical hard disk (physics disk) storage mode is used in high-speed storage systems, the main way. The physical hard disk model of data storage to bypass the logical file system in computer operating system, file organization module and basic file system, the entire hard disk as a large linear array, in sectors as the smallest unit, direct call I/O control layer of hard disk driver, the order of the data written to the specified hard disk sectors.

The basic process of operating system for the operation of the file as shown in figure 4. I/O control for the bottom, the storage device driver and the interrupt handlers, implementing software control of the storage devices. Basic file system sends a standard instruction to the I/O control layer to the storage device to read and write operations.

Mode in order to solve the physical hard disk for file operations between different storage devices generality problem, can use the computer operating system, on the basis of the hardware abstraction layer for the application to provide a set of standardized file operations function. Basic file operations by calling the function, bypassing the logical file system to improve the efficiency of data storage, while avoiding the intricate between different storage device driver program design.

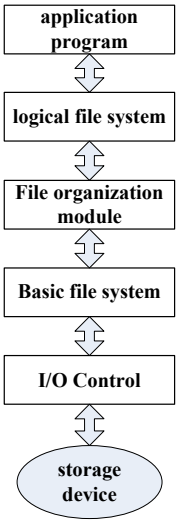

Fig4 Basic file operations process

4 Performance test

- motherboard: based on the Intel 7250 chipsets; CPU: Intel Xeon 3.0 GHz; Operating system: Windows 2000;
- 12 bit A/D converter: dual channel, quantitative; PCI bus controller: PCI9054 (32 bit / 33 MHZ);

In Visula c + + 6.0 environment using c + + language to develop software system, storage system control, equipment state monitoring in the running state of the state of the FIFO (acquisition card, computer cache area, disk storage state) and afterwards the correctness of the recording in the disk array data analysis. By sampling the signal source is 1 MHZ sine signal; Data acquisition card clock frequency in our company office frequency synthesizer MG3633A output sine wave, the signal frequency is adjustable. Each DMA transfers the amount of data is 256 KB, rising acquisition card of the sampling clock frequency, and the whole disk array (588 GB) is full.

According to the above test method, when the sampling clock up to 24 installed base, the rate at which data is input to 96 MB/s (dual channel, 12 bit quantization), the whole system to work normally. When the sampling clock continue to increase, the software system tip speed is less than the data input data storage, and can't work normally, the current system has the highest rate of 96 MB/s storage, have been fully played a PCI (32 bit / 33 MHZ) bus and the disk array storage performance. If adopting high speed PCI bus controller and the disk array, can further improve the performance of data storage.

Summary

General high-speed data storage system based on computer platform, make full use of the current computer system bus structure, to achieve the efficiency of the high speed data storage method and generalized."One-way chain" cache structure was proposed, to solve the computer operating system of real time affect the DMA data for transmission, realize the input data flow and storage of parallel operation. Operation system are analyzed under the basic principle of data storage and logical drive mode affect the performance of the main causes of data storage, and puts forward adopting physical hard disk storage mode, to avoid the logical file system in the operating system on the properties of data storage. By calling the interface functions provided by the operating system files, in a more generalized and standardized method to achieve the high speed, continuous data storage based on computer platform. And only need to upgrade the hardware, can achieve the improvement of the performance of the storage system. With the continuous development of computer architecture, the generalization of high-speed data storage system based on computer platform will be more and more widely used.

Keywords: Doppler, acquisition, software

Abstract. Study a suitable algorithm for implementation of spread spectrum tt&c signals capture software.Analyzes in detail the serial capture pseudo-code algorithm based on FFT, according to the measurement and control conditions, in consideration of pseudo-code doppler and deal with the impact of bandwidth on the basis of, put forward the suitable for software implement methods of capture, primarily through the establishment of a distributed system simulation model and implements a spread spectrum tt&c signals of quasi real-time processing, prove the validity of the method.

Introduction

Along with the computer software technology, the continuous development of signal processing technology, real-time processing technology, as well as the rapid improvement in general computer processing performance, based on general computer processing platform, building software of measurement and control system has become possible.According to the high dynamic and low signal-to-noise ratio under the condition of the spread spectrum signal characteristics, this paper considers the pseudo-code doppler effect of bandwidth and processing, the detailed analysis of the serial capture pseudo-code algorithm based on FFT, on the basis of software implementation of capture method are proposed.[1]Spread spectrum tt&c simulation experiment and through independent research and development of software platform, the capture process of spread spectrum tt&c signals are simulated and analyzed, in order to further the spread spectrum tt&c receiver of software engineering implementation laid a certain technology experimental basis.

1 Traditional rapid capture method based on FFT

In spread spectrum signal capture is to obtain the purpose of signal pseudorandom code phase to a rough estimate, provide initial condition for signal tracking. Carrier code serial capture parallel algorithm based on FFT is due on the carrier frequency search with the method of parallel, thus greatly improve the capture speed of the spread spectrum system.[2]

FFT-based carrier serial parallel code acquisition algorithm implementation process as shown in Figure 1: Input signal after quadrature downconversion and local pseudo-code multiplies the output signal is divided into N segments in each operation cycle, each of M data, and the data segment continuously accumulating points M, N obtained cumulative output value. This is the cumulative result of the use of the N-point FFT transform to do, come to the Doppler frequency. Slide conducted by the pseudo-code serial code phase search to find a frequency that corresponds to the peak value of the Doppler frequency.

2 Algorithm exist problems and improvement

Due to the traditional parallel rapid capture algorithm based on FFT carrier on the pseudo-code phase serial search ways, so the capture speed under the influence of initial phase receiving pseudo-code is bigger.If the local code inside the single dwell time of receiving code and local code the relative phase of sliding produce specific code error, the capture process will lose its significance.

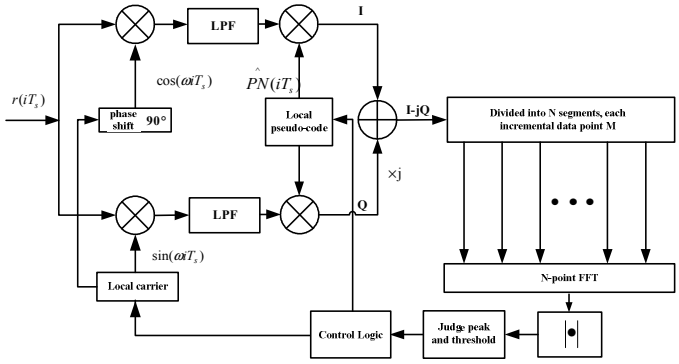

Fig1 Carrier capture parallel algorithm based on FFT implementation block diagram

The relative speed between transmitter and receiver and receive slice width and launch yard yard piece width has established the following relationship:

$$T_{rc} = \frac{1}{1 \pm \frac{v}{c}} T_{sc} \tag{1}$$

Normalized frequency doppler for receiving yard code clock frequency launch code clock frequency difference and yards yards of clock frequency ratio, namely:

$$\varepsilon = \frac{f_{rc} - f_{sc}}{f_{sc}} = \frac{\frac{1}{T_{rc}} - \frac{1}{T_{sc}}}{\frac{1}{T_{sc}}} = \pm \frac{v}{c} \tag{2}$$

The following relationship between the transmitted code and the received code chip width:

$$T_{rc} = \frac{1}{(1+\varepsilon)} T_{sc} \approx (1-\varepsilon) T_{sc} \qquad (\because \varepsilon << 1) \tag{3}$$

When $\varepsilon < 0$, local code and receiving the code phase relationship is shown in figure 2.

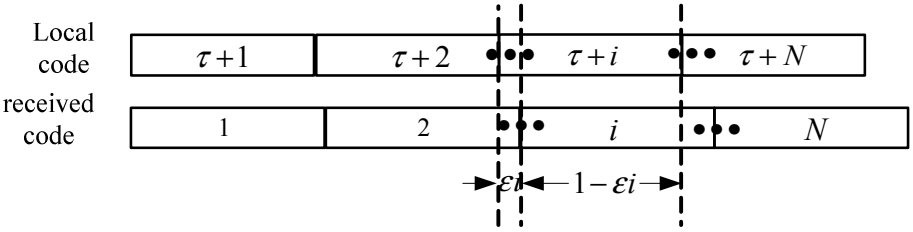

Fig2 $\varepsilon < 0$ native code and received code phase relationship

Accumulate the results as follows:

$$\begin{aligned} y(\varepsilon,\tau) &= \sum_{i=1}^{N} (-\varepsilon i) PN_{i-1} PN_{\tau+i} + \sum_{i=1}^{N} (1+\varepsilon i) PN_i PN_{\tau+i} \\ &= \begin{cases} N\left[1 + \frac{1}{2}(N+1)\varepsilon\right] & ,\tau = 0 \\ -\frac{1}{2} N(N+1)\varepsilon & ,\tau = -1 \\ 0 & ,\tau = +1 \end{cases} \end{aligned} \tag{4}$$

When $\varepsilon > 0$, local code and receiving the code phase relationship is shown in figure 3.

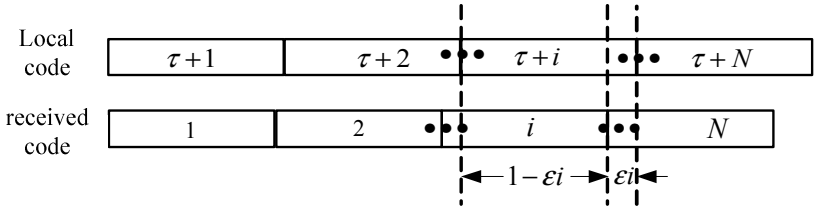

Fig3 $\varepsilon > 0$ native code and received code phase relationship

Accumulate the results as follows:

$$y(\varepsilon,\tau)=\sum_{i=1}^{N}\left[(1-\varepsilon i)PN_iPN_{\tau+i}+(\varepsilon i)PN_{\tau+i}PN_{i+1}\right]$$
$$=\begin{cases} N\left[1-\frac{1}{2}(N+1)\varepsilon\right] & ,\tau=0 \\ 0 & ,\tau=-1 \\ \frac{1}{2}N(N+1)\varepsilon & ,\tau=+1 \end{cases} \tag{5}$$

By the formula (4) and formula (5) shows that whether $\varepsilon > 0$, $\varepsilon < 0$, can make the local code and receiving the code of the coherent accumulation peak decreases.Heap which need to be further derived under the condition of dynamic system is the longest single dwell time.

Pseudo-code doppler frequency calculation:

$$\Delta R_{PN} = R_{PN} \times \frac{f_d}{f_{RF}} \quad (\text{chips/s}) \tag{6}$$

Above within a single dwell time receiving code and local code of relative phase slip should be less than 1/2 a yard, so should be:

$$\Delta R_{PN} T \le \frac{1}{2} \ \text{(chip)} \tag{7}$$

The formula (1) into the formula (2), can be single reside a maximum of integral time:

$$T \le \frac{1}{2\Delta R_{PN}} = \frac{f_{RF}}{2R_{PN}f_d} \ \text{(s)} \tag{8}$$

Given the processing gain and deal with the relationship between the bandwidth:

$$G_s = 10\lg\frac{R_{PN}}{B} \ \text{(dB)} \tag{9}$$

$$t = \frac{10^{\frac{G_s}{10}}}{R_{PN}} \ \text{(s)} \tag{10}$$

Figure 4 to achieve capture n road block diagram.

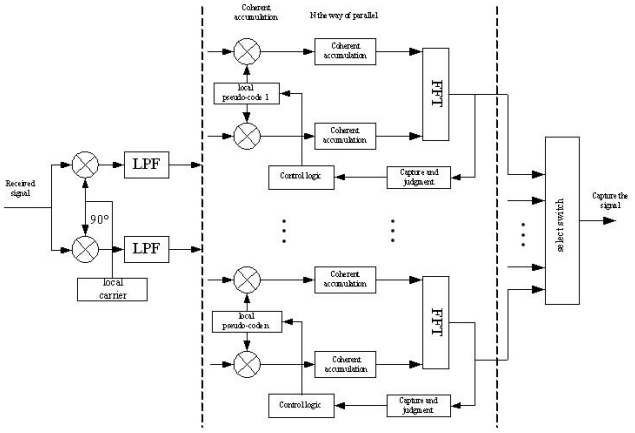

Fig4 The structure of the capture system

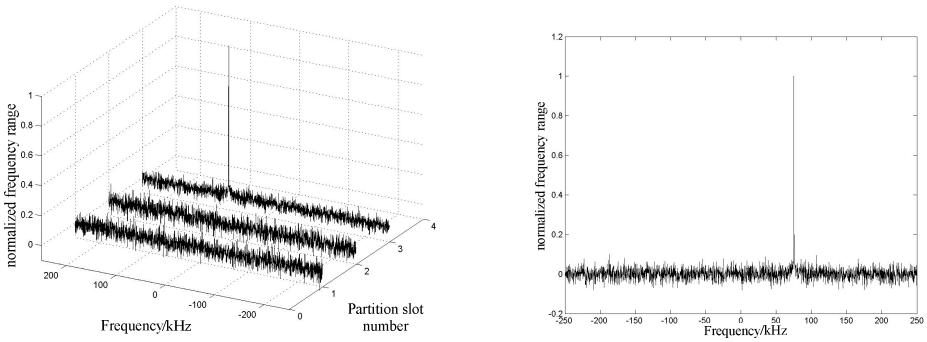
3 Simulation result



(a) Parallel to capture 3 d figure (b) The parallel capture sectional drawing

Fig5 3 road parallel capture peak estimation

The simulation results as shown in figure 5, carrier doppler offset caused by 75 kHz rate 0.34 kHz, so the only way to capture 3 successful. Clear from the figure 3 peak is much higher than other several road, decided to capture success.

Summary

Based on the doppler smaller pseudo-code range doppler, according to the division code doppler frequency range is studied the concrete method of parallel channels, and a simulation analysis was carried out.The simulation results prove that this method is compared with the traditional capture method, realized the measurement and control under the condition of spread spectrum signal capture, and use the distributed method to improve the real-time property of system processing, realized the quasi real-time processing of the signal.

Keyword: Vehicle management; genetic algorithm; multi-resources-constrain

Abstract: As the development of world economy, demand of logistics industry is getting more complex. Vehicle management dispatcher is an important part in logistic system, so how to realize the reasonable dispatcher of vehicles under the circumstance of multi-resources- constrain is the key issue in promoting the prosperity and development of modern logistics industry. The traditional genetic algorithm has the disadvantages that hinder the development and promotion of vehicle dispatcher and slow retard the development speed of logistics industry. Through the research of vehicle dispatcher's demand, we have put forward a new genetic algorithm which is improved, effective and adept to the normal vehicle dispatcher. We have proved that this algorithm is feasible and effective by analyzing the examples.

0 Introduction

With the development and prosperity of world economy and modern technology. A new service introduction of national economy---logistics industry is becoming stronger at a high speed, and it grows to be a pillar industry of economy gradually. The development of logistics industry marks the level of modernization of a country. Logistics industry is called the “accelerator” of the economy of the whole people, the “lubricant” of the reform of the economic structure, and “the third source of profit” of the enterprises. Because of the late start and high require of the development, some bad phenomenons appear in the logistics industry in China, such as backward infrastructure, low specialization, and high energy consumption while low productiveness, and so on[1].

Logistics distribution is the foundation of logistics industry's development. We can ameliorate these disadvantages if we react fast and realize the modern distribution, and it is also good for resolving a series of social problems, such as the traffic jams in big city and lack of energy resources. The best vehicle dispatcher is the key issue to complish the whole logistics and distribution preferably. Dantzig and Ramser firstly put forward the issue of vehicle dispatcher, namely the vehicle routing. After the persistently fast growth in sixty years and the long time study and analysis by scholars, now vehicle dispatcher has become the popular research project about the combination optimal problem in operational research. In our fast-paced as well as high-level production and social life, all the allocated or administrative problem such as posting the mail and freight, dispatching the railway car, transferring the seaport wharf, dispatching the public transportation, and so on, all these issues can be judged as the vehicles dispatching problem abstractly. With the conjunct application and development of E-commerce and Internet communication, the logistics and vehicles dispatching are broadly applied to some highly circulating fields, such as all kinds of national chains and large-scale businesses. Thus, the research of vehicles dispatching algorithm can improve the efficiency while lower the energy consumption, so it has high scientific meaning and practical value.

With the fast changes of logistics industry, the traditional genetic algorithm we are using now is extremely not adapted to the fast development speed and reform[2]. We will have to improve the traditional genetic algorithm if we want to adapt to the fast pace of modern logistics industry. After practicing for a long period of time, we make the new genetic algorithm adapted to the fast pace of modern logistics industry. Only in this way can we follow the development pace of logistics industry, and we not only economize the cost for later research but also extend the life of vehicles, thus realize the most optimized dispatcher and allocation, promote the better development of logistics industry, and enhance the comprehensive national strength.

2 Multi-Resources Constraint and Dispatching Model

2.1 Vehicle Dispatching and Multi-Resources Constraint

The vehicle dispatching in logistics needs the technology to realize the optimized measure under the multi-resources constrained condition, that is to say, to realize the optimization of expense, pcu and transportation distance, namely make the whole expense in dispatching the least, including the fixed starting fees of vehicles, driving fees, waiting fees, serves fees and punishment fees. At the same time, we should achieve the most cargo delivery with the least transport vehicles, supposing the routine is different, neither is the using vehicles, and we also need to complete the whole dispatching mission in the shortest distance. The most important is to complete the whole dispatching mission in the shortest time, including the approaching time of the vehicles, the waiting time and delay time and service time.

2.2 Multi-Resources Constraint

At present, foreign scholars pay much attention to the dispatcher of fixed need about the research of vehicle dispatching issue, including many resources-constrained conditions and limitations. We can propose these constraint into five kinds: mileage resources-constraint, motorcycle type resources-constraint, full loaded resources-constraint, non-full loaded resources-constraint, and time window resources-constraint. Summarized former research production, we find that there are many kinds of algorithms and solutions about vehicle dispatching issue, basically including the following five kind. The first one is branch and bound algorithm, which makes the best dispatching through the classification. .The second one is saving the distance algorithm, which regard save as the premise and foundation of optimum solution, and then optimize the vehicles dispatching. The third one is insertion algorithm, which inserts reasonable DC(distribution center) in appropriate region so as to optimize the vehicles dispatching. The forth one is tabu search algorithm, which prevents some algorithm that is not appropriate to this field. The fifth one is genetic algorithm, which applying genetic theory to realize the optimization. The last one is ANN algorithm, which adopts nerves classification to realize the optimization. In daily life, genetic algorithm is often applied. However, the disadvantage of genetic algorithm is increasingly obvious, so we need to greatly improve this algorithm so that it can be applied to practice and make users familiar to this method and get good practical result as well.

2.3 Building the Vehicles Dispatching Model Under Different Resources-Constraint

In order to study the vehicle dispatching issue, we need to build the models of vehicles dispatching in different resources-constraint. The first thing to do is to estimate the dispatching conditions of vehicles previously. In common, the more resources-constrained conditions in vehicles dispatching, the more complex of the arrangement of driving routine, and the less mission of every vehicle under resources-constraint, that is to say, the less dispatching mission that a vehicle needs to complete in practice, so the loading rate of every vehicle will be lower. Thus, we need more vehicles to dispatch missions, in order to realize the flexible arrangement of driving routine, we reserve the vehicles previously. The particular formular is as follows:

$$m = [\sum_{i-1}^{n} q_i / \partial Q] + 1 \tag{2-1}$$

In this formular, m is the total number of the dispatching vehicles, Q the standardized load, q_i the need of number i, and "$[*]$"is the integer function. We require that $0 < \partial < 1$.Generally the more complex lift trucks, the more resources-constrained conditions. However, that will make the ∂ gets smaller, that is to say the load everyday will lower greatly. Meanwhile, we also can get if the vehicles we need in the whole dispatching mission are getting more, the smaller of the ∂, and the smaller, the better.

3 Program and Improve the Genetic Algorithm

3.1 the Genetic Algorithm

The Genetic Algorithm is firstly put forward by J.Holland, and re-identified and deduced by Hollanl later on. Its core idea is every outstanding individual will appear the direction of index increasing in every dynamical population biology. That is to say, it is convergent, so it can be applied in practice preferably. This algorithm is a randomly searching and calculating method which has better adaption and flexible optimized object, so we do not need the successive optimized object, or the optimized object to differentiate, or has the good stability and parallel searching ability[3]. At the same time, the genetic algorithm does not need the initial solution, and arbitrary initial population biology can operate and outcome. We use randomized optional strategy in this algorithm, that is to say, it makes the outstanding individual go to the next generation through the survival of the fittest, and then after the cross - fertilization and Genetic behavior, it realizes weakness or disappearance.

Compared to other algorithms, the genetic algorithm has its own merits. The genetic alg orithm adopts the evolution mechanism, and it carries out the searching process in the whol e situation, averting the localization. Even if the adaptive function is discontinuous or irregu lar, the genetic algorithm can find the optimized solution of whole situation. And also, it h as wonderful parallel processing and can realize the combination with other algorithms, espe cially adapted to the issues which have large scale and broad distribution.

Recently, Genetic Algorithm (GA) is widely applied to the optimization problems in different fields, which arouses more and more people's interest of study and application due to its good characteristics that the Genetic Algorithm is not dependent on the problem model, along with global optimality, implicit parallelism, high efficiency and solution of the nonlinear problem.

GA is applied to the problem of constrained optimization; the constraint processing has become a very important link . There are two kinds of solutions: one adopts the changed operator in the operation, producing always the legitimate offspring from the legal parent satisfying the constraint conditions and making the search in the legal and valid space all the time; Another is to apply the corresponding punishment to the objective function in the adaptive function according to each individual to satisfy the different constraints so that the constrained problems are converted into unconstrained problems. The main steps of genetic algorithm are as follows :

a. Establish the initial group composed of a string at random;

b. Calculate the fitness of each individual.

c. According to the genetic probability, the following operations is applied to generate new group:

Copy: The existing excellent individual copied is added to the new group, and the bad individual is removed;

Hybridization: Two individuals picked out are exchanged, and the new individual is added to new groups;

Variation: One particular character is changed randomly in an individual; the new individu al is added into new groups;

d. The steps of (2), (3) are carried out repeatedly to reach the termination conditions, and the best individual is chosen as a result of the genetic algorithm. It is the key to practical application to choose the encoding strategy and convert the parameters into a string and the accurate fitness. The initial population N=200，the crossover probability P_c=0.95, the mutation probability P_m=0.01，the function of minimum inventory cost is as the objective function, the objective function is as fitness function directly, namely. The optimal purchase quantity and inventory is obtained in the following table with iterations of 53 times.

4 Conclusion

We discuss the analyze the genetic algorithm of vehicle dispatching under the multi-resources constraint and the improved genetic algorithm in detail, changing the disadvantage of slow convergence in the traditional genetic algorithm, making the application of improved genetic algorithm become much wider, thus promote the application of vehicle dispatching in the genetic algorithm, the growth of logistics, as well as the development and ability of the economy.

Keywords: Logistic Regression; Epistasis; GWAS; LASSO-penalized

Abstract. Extensive studies have shown that many complex diseases are influenced by interaction of certain genes, while due to the limitations and drawbacks of adopting logistic regression (LR) to detect epistasis in human Genome-Wide Association Studies (GWAS), we propose a new method named LASSO-penalized-model search algorithm (LPMA) by restricting it to a tuning constant and combining it with a penalization of the L_1-norm of the complexity parameter, and it is implemented utilizing the idea of multi-step strategy. LASSO penalized regression particularly shows advantageous properties when the number of factors far exceeds the number of samples. We compare the performance of LPMA with its competitors. Through simulated data experiments, LPMA performs better regarding to the identification of epistasis and prediction accuracy.

Introduction

With the development of high-throughput genotyping technologies, it is possible for researchers to assay hundreds of thousands of single-nucleotide polymorphisms (SNPs) [1]. SNPs are the most abundant source of genetic variation in human genome, the number of which can reach millions in public datasets. Despite the notable success in identifying genes responsible for monogenic diseases, the pathogenesis of complex diseases still remains mysterious. Identification of disease-causing genes and epistasis requires extensive estimates of multiple potential genetic sites.

LR is a standard tool for modeling main effects as well as interactions in case-control studies. However, for the SNP data in GWAS, LR models have significant drawbacks: (1) In the contingency table, predictors defining an interaction may be empty, which should need special parametrization; (2) With many candidate loci, predictors can be correlated resulting in further degradation of the model; (3) The amounts of genotype factors and their interactions can create lots of parameters, and the problem of overfitting arises with relatively small samples; (4) These problems are aggravated when the interaction order increases.

For these and other reasons, we have to look for alternative methods for identifying epistasis. The LASSO approach tends to set many of the coefficients to zero, leading to a sparse model, a property generally weakened with an L_1-norm regularization. We will use the penalized method with the LASSO penalty to detect significant main effects and epistasis. We proposed LASSO-penalized-model search algorithm to search models of multiple risk predictors in large demographic studies.

In this article, we present a new algorithm called LASSO-penalized-model search algorithm, denoted as LPMA. We modify the LR criterion by restricting it to a tuning constant and combining it with a penalization of the L_1-norm of the complexity parameter, these adjustments produce significant effects. Because of the penalization, collinearity among the predictors does not degrade fitting much, and the number of elements in the selected model is essentially not influenced by sample size.

We compare our algorithm with screen and clean algorithm [2] proposed recently, an efficient tool to identify gene interactions. Extensive experimental results show that LPMA performs well both on the computation time and power.

Methodology

LASSO-penalized-model search algorithm. Our LASSO-penalized-model search algorithm is implemented with a multi-stage study approach. The purpose of the following stage is to validate the findings of the previous stage. All stages are likely to yield predictors for the whole genome as genome-wide platforms is becoming more and more cost-effective.

Following the Occam's razor principle of parsimony, we use statistical interactions to explore SNP-SNP interactions, even though SNP-SNP interactions can be considerably more complex in reality [3].

For main effects, we construct such a model:

$$G(x) = \sum_{i=1}^{n}(y_i - \mu - \sum_{j=1}^{p} x_{ij}\beta_j)^2 + \lambda\sum_{j=1}^{p}|\beta_j| \le s \quad (1)$$

Similarly, we build the epistasis model when considering interactions:

$$G(x) = \sum_{i=1}^{n}(y_i - \mu - \sum_{j=1}^{p} x_{ij}\beta_j - \sum_{k=1}^{p}\sum_{l=1}^{p} x_{ik}x_{il}\beta_{kl})^2 + \lambda\sum_{k=1}^{p}\sum_{l=1}^{p}|\beta_{kl}| \le s \quad (2)$$

The goal is to select those models that encode the variables or pairs of variables that best separate cases from controls. Our LPMA has four steps.

Step 1: This is the pre-selection step without utilizing the penalty parameter s, so the objective function is $G(x) = \sum_{i=1}^{n}(y_i - \mu - \sum_{j=1}^{p} x_{ij}\beta_j)^2 + \sum_{j=1}^{p}|\beta_j| \le s$, which is different from Eq. 1 by omitting the parameter that is utilized in step 3. This strategy only considers the tuning parameter s, thus reducing the computational burden and computing time to a certain extent. First of all, we only consider those predictors that pass quality control (QC) criterion. Then apply this objective function to these terms to estimate main effects. The forward stepwise regression has been investigated in several previous literatures. Recall how forward stepwise regression works:

1. Begin with all coefficients $\beta_j = 0$;
2. Seek out the predictor x_j most correlated with response y_i, and then add it into the model. Take residuals $r = y_i - y_{ithat}$;
3. Continue, at each step adding the predictor most correlated with r into the model;
4. End when all predictors are tested.

In this paper, we take a more "democratic" version of forward stepwise regression:

1. Begin with all coefficients $\beta_j = 0$;
2. Seek out the predictor x_j most correlated with response y_i, and then add it into the model. Take residuals $r = y_i - y_{ithat}$;
3. Increase the coefficient β_j in the direction of the sign of its correlation with y_i. Take residuals $r = y_i - y_{ithat}$ along the way. Stop when some other predictor x_k has as much correlation with r as x_j has;
4. Increase (β_j, β_k) in their joint least squares direction, until some other predictor x_m has as much correlation with the residual r;
5. End when all predictors are tested.

Surprisingly it can be shown that, with one modification, this procedure gives the entire path of lasso solutions, as s is varied from 0 to infinity. The modification needed is: if a non-zero coefficient hits zero, remove it from the active set of predictors and re-compute the joint direction. In this step, we use the parameter s to control the number of predictors to enter the model and denote the active set of predictors as S_1 and the number of elements as $num(S_1)$.

Step 2: This is a screen step using data derived from step 1. To discover interactions, we update the active set of predictors derived from step 1 by adding or deleting some elements. We obtain a new active set of predictors S_2 by adding all the pairwise interactions of the remaining elements and delete those not meeting certain conditions. It should be noted that the marginal p-value of the pairwise interactions is not bigger than p, which is a threshold defined by the user, while those whose marginal p-value are omitted. It is commended that the maximum of $num(S_2)$ is five times of $num(S_1)$,

otherwise we perform marginal tests on each effect and select the 5*num(S_1) effects with the smallest p-values.

Step 3: In this step, we adopt the LASSO penalty (L_1) as shown in Eq. 3 to do variable selection. The complexity parameter λ measures the trade-off between data fitting and the sparsity of the model to select the one that includes the variables or pairs of variables that best distinguish cases from controls. Let p(x) be the probability that y = 1, given x, and let $p_i = \log[p(x)/(1-p(x))]$. For a fixed λ, The coefficient vector $\theta = (\mu, \beta_1, \ldots, \beta_p)$ is calculated by maximizing the log likelihood:

$$L(\theta) = \sum_{i=1}^{n} [y_i \log p_i + (1-y_i)\log(1-p_i)] \tag{3}$$

Utilizing data sets derived from step 2, we apply Eq. 3 to S_2 and shave those elements whose coefficient is zero. We obtain the model including elements satisfying $\{j : \beta_j \neq 0\} \cup \{(k,l) : \beta_{kl} \neq 0\}$, then purify the model by deleting these elements not satisfying $\{j : |T_j| > c\} \cup \{(k,l) : |T_{kl}| > c\}$ where $c = Z_{\alpha/(2m)}$, and m is the number of elements in the model. T_j and T_{kl} are the t-statistic values for main effects and interactions respectively.

Step 4: It is obvious that the model step 3 produces is relatively sparse. There is a general tendency for the LASSO-penalized-model search to go wrong on the conservative side in choose coefficients, in other words, there is a quite high probability of containing all relevant coefficients at the expense of comprising some noise elements [4, 5]. Hence it is necessary to take a much more careful exploration on the terms that passed step 3. We implement this request by putting them into a parametric logistic regression and calculating the significance of each element at level α. The parameter α is chosen based on prediction accuracy rather than on an ad hoc basis. The significant elements enter the logistic regression again and generate the final model.

Post-processing . This post-processing is proposed by [6]. We here utilize the same procedure that can be described as follows to minimize false positives:

We denote all the epistatic interactions identified by our algorithm as S_{old}, and the set of epistatic interactions after the post-processing as S_{new}, which is a null set at first. We directly put I_i that belongs to S_{old} into S_{new} as long as I_i does not have any element the same with that of all interactions in S_{new}. Otherwise, if one epistatic interaction in (assume it is I_j) S_{new} has at least one same element with I_i, then we use their p-values to make a decision. If the p-value of I_j is larger that that of I_i, then we replace I_j with I_i. If not, I_i is not permitted to be put into S_{new}. After this procedure, we obtain a final set of loci interactions S_{new} that includes the most significant epistatic interactions detected by our algorithm.

Results and Analysis

The simulated data generated by the simulator Hapsample, which is accessible from the web site http://www.hapsample.org in public. We estimate the performance of our LPMA by comparing it with screen and clean (SC), an efficient tool for identifying interactions in genome-wide association studies proposed recently. We use a moderate number of predictors in the simulation experiments. Unless otherwise noted, the default experimental setting is as the following: #predictors = 10000, #individuals = 400, the linkage disequilibrium is 0.25, and the control-to-case ratio is 1.

In population genetics, linkage disequilibrium is described as the non-random association of alleles at two or more loci that descend from single ancestral chromosomes. Linkage disequilibrium is wholly a measurement of proximal genomic space [7]. The level of linkage disequilibrium is associated with various factors, such as the rate of recombination, genetic linkage, the rate of mutation, selection, genetic drift, population structure, non-random mating and so on. To make the experiment more convincing, we test the impact of linkage disequilibrium on power for detecting true predictors.

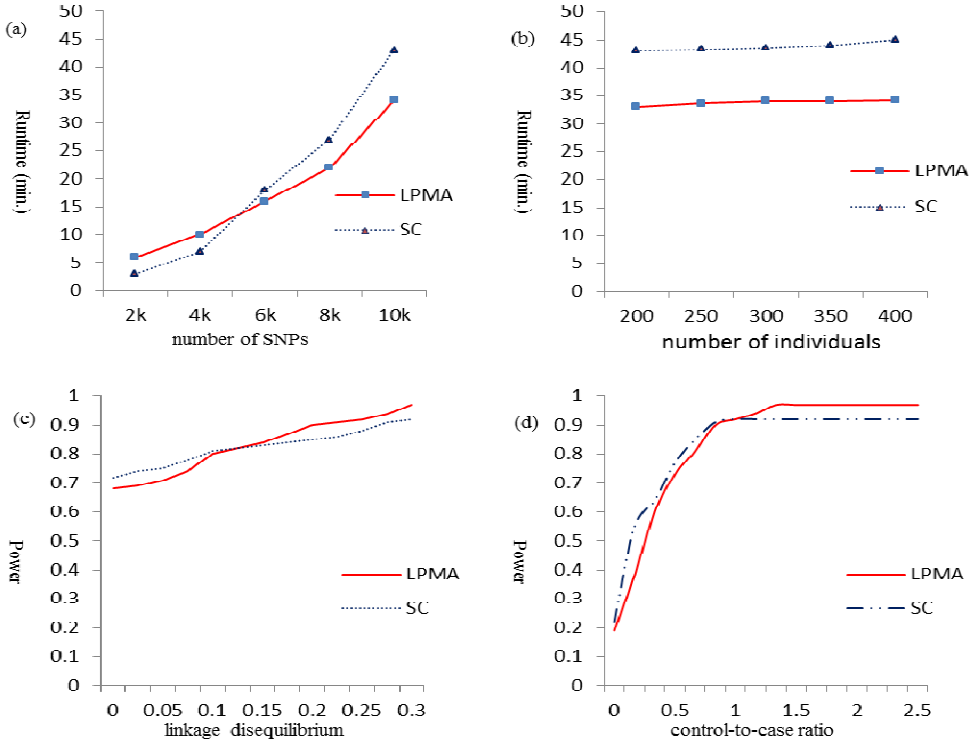

Fig. 1 Comparison of LPMA and SC about runtime and power

Fig. 1 (a) and (b) depicts the runtime comparison between LPMA and SC as the number of SNPs (predictors) and the number of individuals varies respectively. Fig. 1 (c) and (d) illustrates the power comparison when varying the linkage disequilibrium and the control-to-case ratio. It can be concluded that when the number of predictors is small, SC performs better than LPMA, which may be caused by those redundant pre-operations in LPMA, but LPMA outshines SC when the number of predictors becomes larger, which indicates that LPMA is more suitable to be applied to GWAS. Obviously, the number of individuals has little impact on the property of the two algorithms. When discussing the issue of power, the two algorithms approximately have equal shares.

Conclusions and Future Work

In this paper, we applied the LASSO-penalized-model search algorithm to detect epistasis. LPMA produces acceptable prediction accuracy and identifications of significant predictors. It is believed that this multi-step algorithm is an effective procedure to satisfy two demands simultaneously, generalizability and sparsity. Regarding to the computation time and power, sufficient experiments show that our LASSO-penalized-model search algorithm presents a better performance than its nearest competitors in extensive simulation studies.

In this article, we focus on the dichotomous response that can be coded as binary variables. Many literatures involve responses measured as continuous variables, and parallel methods such as GBOOST [7] based on CUDA and CEO [8] based on Google's MapReduce framework have been adopted into GWAS. In our future work, we will try to apply the idea of our current algorithm to quantitative responses using parallel technology.

Keywords: continuous attributes; weighted index; clustering number; fuzzy clustering algorithm.

Abstract. In view of the discretization of continuous attributes of civil aviation radar intelligence data, this paper proposes a fuzzy partition algorithm of continuous attributes based on weighted index and optimization of clustering number, and its automatic determination of optimal weighted index m and optimal clustering number c overcomes the shortcomings of current attribute fuzzy methods of manual determination of classification number and no consideration of geometry data. The experimental results verify the validity and feasibility of fuzzy attribute discretization of civil aviation radar intelligence data characteristics.

1. Introduction

Fuzzy clustering is an important branch of unsupervised pattern recognition, has been widely applied in the field of image processing, pattern recognition, time series prediction and parameter estimation, and in practice, fuzzy clustering means (FCM) has been the most widely used fuzzy clustering algorithm.

FCM algorithm is an unsupervised classification algorithm, and the weighted index m and clustering number c, its two important parameters, should be determined in advance. If the parameters are inappropriately selected, the classification results may not match with the real structure of data. According to some literatures, [1] "parameter m controls the sharing degree between the fuzzy classes". Currently, implementation of FCM algorithm is usually based on experience or experiment and artificial selection method to determine the initial parameters of the algorithms for clustering; however, how to select the optimum m and optimal c has not been solved effectively.

In view of the above problems, according to the fuzzy decision theory and fuzzy clustering validity index V_{kwon} of data geometric structure, the weighted index m and c are discussed, and the methods to realize optimum parameters and a fuzzy clustering algorithm based on weighted index and clustering number optimization. As for application of FCM clustering algorithm, the weighted index and clustering number should be specified manually.

Description of FCM clustering algorithm. FCM clustering algorithm obtains membership of each sample site to the sample center through optimizing objective function Jm, so as to determine the membership of sample site. Objective-function-based fuzzy clustering method is put forward firstly by Ruspini [2], but the real effective method is proposed by Dunn[3] in 1974. Hard c-means (HCM) clustering algorithm is extended to the fuzzy case by Dunn. In that same year, Bezdek generalizes Dunn's method and establishes the FCM clustering theory. Through optimizing objective function, the membership of each sample site to the sample center is obtained, and accordingly membership, of sample site determines is determined. The algorithm is described as follows:

Suppose $X = \{x_1, x_2, ..., x_n\} \subset R^s$ is the data set, n is the number of elements in data, c is the clustering number centers, $d_{ij} = \| x_i - v_j \|$ is the Euclidean distance between sample site x_i and the cluster center v_j. u_{ij} is the membership of the ith sample belonging to the jth center, $U = [\mu_{ij}]$ is partition matrix of $n \times c$ of fuzzy c, and $v = [v_1, v_2, ..., v_c]$ is center matrix of fuzzy clustering $s \times c$.

Definition 1 If any $U \in M_{fc}$ in (1) is met, fuzzy partition of data set X is defined.

1. $M_{fc} = \{U \in R^s \mid \mu_{ij} \in [0,1], \forall i, j; \sum_{i=1}^{c} \mu_{ij} = 1, \forall j; 0 < \sum_{i=1}^{c} \mu_{ij} < n, \forall i\}$

Each element $\{\mu_{ij}, 1 \le j \le n\}$ in U matrix defines a subset of fuzzy clustering $\tilde{S}_l$.

2. $\tilde{S}_l = \mu_{l1} / x_1 + \mu_{l2} / x_2 + \cdots + \mu_{\ln} / x_n$

where μ_{ij} indicates that the membership degree of jth sample belonging to clustering $\tilde{S}_l$.

3. $J_m(U,v) = \sum_{i=1}^{n} \sum_{j=1}^{c} \mu_{ij}^m \cdot d_{ij}^2$

$J_m(U,v)$, extended from HCM and ISODATA [5] algorithm, is infinite families of the objective function defined by Bezdek [4]; m is weighted index, and it plays an important role in regulating fuzzy degree of clustering, μ_{ij} is the membership function, and:

4. $\mu_{ij} = 1 / \sum_{i=1}^{n} \left\{ \frac{d_{ij}}{d_{kj}} \right\}^{\frac{2}{m-1}}$

The FCM algorithm comes from optimization steps of the following formula, i.e. through (5) iteration of the first-order necessary conditions.

5. $\min_{M_{fc}} \left| J_m\left(U,v\right) \right|$

In (5), the first order necessary conditions of variables $\left(U,v\right)$ correspond to (4) and (6).

$$v_i = \frac{\sum_{j=1}^{n} \left(\mu_{ij}\right)^m x_j}{\sum_{j=1}^{n} \left(\mu_{ij}\right)^m}$$

It is identified [6] that FCM algorithm converges to local minimum so as to minimize the objective function J_m, thus a fuzzy c of X to divide U^*.

Optimized algorithm based on the optimal weighted index m^* and optimal clustering number c^*

In order to obtain the optimal value of the weighted index m and according optimal clustering number of samples, the optimal clustering number c^* according to methods to gain m based on fuzzy decision and validity index V_{kwon} of geometry structure of specific data sets.

Method to obtain optimal weighted index m^* based on fuzzy decision-making. According to the fuzzy decision theory proposed by Bellman and Zedeh, fuzzy objectives G and fuzzy constraints C are constructed, and the decision D is formed by the intersection of D and C, i.e.

1.When G and C are regarded as fuzzy sets, they are respectively characterized by the membership function, so the membership function of fuzzy decision can be expressed as:

2.The final decision results are the alternative solutions of decision space.

3.Therefore, in order to optimize m with the help of fuzzy decision theory, appropriate fuzzy goal, fuzzy constraints and corresponding membership function should be constructed. In this study, fuzzy goal G is defined as the objective function $J_m(U;v)$, the fuzzy constraint C is defined as possibility for partition $H^*(U;c)$. Accordingly, the fuzzy decision about the optimal weighted index m^* can be expressed as:

4.Next, the membership functions of fuzzy objectives G and fuzzy constraints C are defined as μ_G and μ_C, two of which are ensured of the same increase or decrease, as is represented by the following formula:

5.Then the fuzzy decision value of optimal weighted index m^* is m corresponding to the maximum membership degree in intersection of fuzzy subset of G and C, namely, the m corresponding to nodal value.

Method to determine the optimal clustering number c^* based on the validity index V_{kwon}. The fuzzy clustering objective function with large membership degree and minimize possibility of fuzzy clustering with large membership degree for partition entropy, so that the clustering can not only express similarity information between samples and realize good separability between class samples. However, in the traditional method, the value of c is artificially selected, so the final clustering result can not be ensured the optimal partition. In this study, validity index is adopted for further iteration of the initial clustering number, thus clustering center number is automatically realized, and finally the optimal clustering number is gotten. The algorithm process is shown below (woth initial weighted index range $m = 1.0, 1.1, \cdots, k$ and $step = 0.1$):

(1) The initial clustering number $c = 2$;

(2) Initialized clustering center v_i, $i = 1, 2, \cdots, c$; ,;

(3) The number of iterations $p = 0$, the distance d_{ij} between various data and the cluster center is calculated, membership function matrix $U^{(0)} = (\mu_{ij}^{(0)})$ is calculated of, wherein $j = 1, 2, \cdots, n$ $i = 1, 2, \cdots, c$, μ_{ij} is the element on ith row jth column of matrix U, meaning the membership of jth data on the ith clustering center. Constraint relation is represented by formula (1);

(4) v_i of C clustering centers is recalculated, $i = 1, 2, \cdots, c$.

(5) The membership function matrix U is recalculated;

(6) The objective function $J_m^{(p)}(U;\ v)$ and the possibility of partition entropy $H^{*(p)}(U;c)$ are calculated;

If $\left|J_m^{(p)}(u,v) - J_m^{(p-1)}(u,v)\right| \le \varepsilon$ and $\left|H^{*(p)}(u,v) - H^{*(p-1)}(u,v)\right| \le \varepsilon$, convergence displays, then the clustering numbering iteration ends, otherwise, step (4) is turned to;

(7) If the validity index V_{kwon} reaches convergence conditions, the process ends, then we get local optimum clustering number c_m^*, minimum objective function $J_m^*(U;v)$ and the minimum probability partition entropy $H_m^*(U;c)$ are obtained with the current value of m. Otherwise, the clustering number $c = c + 1$, and then step (2) is turned to;

(8) $m = m + 0.1$, if $m \le k$, step (1) is turned to, or, the process ends. $\mu_G(m)$ and $\mu_C(m)$ of m are obtained; according to formula (13), the optimal weighted index m^* is obtained, local optimum clustering number c_m^* of m^* is the optimal clustering number c^*.

Fuzzy algorithm to classify aviation radar intelligence attributes based on weighted index and clustering number optimization

This new algorithm is the improvement of previous studies. According to fuzzy decision theory and probability partition entropy function, the key parameters in FCM algorithm are summarized, namely the selection of optimal weighted index m, and then through the iteration of validity index V_{kwon}, the optimal clustering number is obtained, thus no manual selection of parameters in the original algorithm is eliminated, and local optimum is avoided; at the same time, clustering classification

based on dataset geometric structure is realized, so that fuzzy attribute partition is more consistent with the actual data. This section presents a discretization algorithm for continuous attribute of civil aviation radar intelligence based on the above algorithm, and establishes membership functions of fuzzy attribute partition.

Fuzzy attribute partition. Firstly, the continuous attributes of civil aviation radar intelligence deserve fuzzy partition, assuming the following definition:

Suppose the database sample $D = \{x_1, x_2, \cdots, x_n\}$, in which $x_1, x_2, \cdots, x_n$ means different database records, n is recorded sample number; for the continuous attributes in databases, for continuous attribute number; $QA = \{q_1, q_2, \cdots, q_r\}$ means the continuous attribute in database, r is the number of continuous attributes, $DS_i = \{x_{1i}, x_{2i}, \cdots, x_{ni}\}$ is the set q_i of attributes corresponding to n recorded samples, $FP = \{FP_1, FP_2, \cdots, FP_r\}$ is the set of final fuzzy partition of all attributes; $FP_i = \{f_1, f_2, \cdots, f_c\}$ is the fuzzy set of single continuous attribute, and c is the number of fuzzy sets.

For given civil aviation radar intelligence database samples D, only the classification attributes and continuous attributes are considered in this paper. With the continuous attribute partition as an example, the attribute value set of $q_i \in QA$ in D deserves clustering classification with the improved FCM algorithm, the best fuzzy partition FP_i of attribute q_i and its fuzzy c - partition matrix $U_i = [\mu_{jk}(x_i)]_{n \times c}$ are obtained, in which $\mu_{jk}(x_{ji})$ means the membership degree of attribute value of jth of attribute q_i to fuzzy set $f_k \in FP_i$, and $v_i = \{v_{i1}, v_{i2}, \cdots v_{ic}\}$ means fuzzy classification center, so do division of other attributes.

Pseudo code of algorithm for fuzzy partition of civil aviation radar intelligence data attribute is shown.

1. For each $q_i \in QA(i = 1,2,\cdots,r)$
2. (Read DS and $m_{\max}$, namely the upper limit of improved FCM algorithm)
3. FP_i, U_i, v_i== new FCM ($q_i, DS_i, m_{\max}$)
4. For each partition $f_k \in FP_i$
5. label f_k appropriately (marking of fuzzy set)

Each continuous attribute deserves this procedure, until all the attribute partition ends. It is displayed that this attribute partition method is based on the geometric structure of data set, then the optimal clustering number and classification center are automatically obtained, thus the empirical determination of clustering number is eliminated.

Calculation of Membership function of fuzzy attribute set. After calculation of fuzzy partition of all continuous attributes, according to membership degree m of fuzzy attribute set, the membership function of fuzzy set of all continuous attributes is calculated.

A variety of ways can be used to determine membership function, such as Wang Shitong's generalized membership function model $\exp(-|a_1 x + a_2|^r)$ can achieve approximated membership function of various fuzzy sets. But in actual engineering application, the membership functions of fuzzy sets are usually expressed as triangular, trapezoidal or Gauss type functions, in order to facilitate calculation, triangle function is selected. With q_i attribute and its fuzzy partition FP_i mentioned above as example, the concrete methods are as follows:

Suppose $X_i^k = \{x_{pi} : \mu_{pk}(x_{pi}) \geq \mu_{jk}(x_{ji}), \forall j \in (1,\cdots,c)\}$, find out the attribute value of minimized membership located on both sides of center in $X_i^k \cup \{v_k\}$, let the minimum value of the left

membership attribute be x_{li}, membership be $\mu_{lk}(x_{li})$, attribute value of left membership minimum be x_{ri}, and membership be $\mu_{rk}(x_{ri})$, then the triangular fuzzy value of kth fuzzy sets (a, v_k, b) is:

$$f(x)=\begin{cases}\dfrac{x-a}{v_k-a} & a\le x\le v_k\\ \dfrac{b-x}{b-v_k} & v_k\le x\le b\\ 0 & x<a or x>b\end{cases}\qquad \begin{cases}a=x_{li}-\dfrac{\mu_{lk}(x_{li})(v_k-x_{li})}{1-\mu_{lk}(x_{li})}\\ b=x_{ri}-\dfrac{\mu_{rk}(x_{ri})(v_k-x_{ri})}{1-\mu_{rk}(x_{ri})}\end{cases} \tag{1}$$

Generation of recorded fuzzy sets. After attribute fuzzy partition, membership function of all fuzzy sets are made use of to transform the original database record into fuzzy record sets, and this process is a necessary step for subsequent data mining method.

If the entry corresponds to continuous attributes, then the fuzzy partition number of attributes and record of database D for fuzzy set membership function are transformed. The transformed fuzzy entries are divided corresponding to fuzzy partition number, and each item value is the membership of corresponding fuzzy set $\mu\in[0,1]$, the threshold value of m can also b set, and those beyond threshold value do not belong to the corresponding fuzzy sets.

If the entry's corresponding attributes are classification properties, the corresponding entries are classified in accordance with the number of attributes, each subvalue's membership according to the category is $\mu=\{0,1\}$.

In addition to previously defined symbols, the additional following symbol definitions are as follows: is is is the classification attribute in database; $C=CA\bigcup QA$ is attribute sets; D' is the transition variables to be converted in database D; E is eventual converted database.

$D'=D$
$D''=\varnothing$
for each $c_i\in C$
  if $c_i\in CA\quad (i=1,2,\cdots,q)$
    for each record $x_j\in D'\quad (j=1,2,\cdots,n)$
      x' = replace value v_{ij} by $\mu_{ij}\in\{0,1\}$
      $D''=x'\bigcup D''$
  if $c_i\in QA\quad (i=1,2,\cdots,r)$
    for each record $x_j\in D'\quad (j=1,2,\cdots,n)$
      for each $f_x\in FP_i$ corresponding $c_i\ \ (k=1,2,\cdots,s)$
    μ_{ijk} =membership corresponding to crisp value v_{ijk} in fuzzy partition （attribute） f_x
    according to triangle membership function (a, v_k, b)
      x' = replace v_{ijk} by μ_{ijk}
      $D''=x'\bigcup D''$
  $D'=D''$
  $D''=\varnothing$
$E=D'$

The above process helps to convert the original record set D into fuzzy record set E, Each continuous attribute deserves this procedure, until all the attribute partition ends. It is displayed that this attribute partition method is based on the geometric structure of data set, then the optimal clustering number and classification center are automatically obtained, thus the empirical determination of clustering number is eliminated.

4. Experimental results and analysis

In order to verify the effectiveness of the optimum weighted index m^* and the optimal clustering number c^* in this algorithm, experiments are carried out on a set of IRIS data, and when two objective function difference I less than 0.001 or the number of iterations is greater than 200 times, the iteration terminates.

To initialize clustering center, the method proposed by Katsavounidis [7] I adopted, this algorithm is based on distance optimization, with no threshold set, as is shown below:

(1) The maximum norm data sample is taken as the initial site of first cluster center;

(2) The data sample farthest away from the first initial site is taken as the second initial value;

(3) The minimum distance between those non-selected sample data and all the initial sites are respectively calculated;

(4) The data sample corresponding to maximum value of all minimum distances is selected, and take is as initial site of next cluster center;

(5)Repeat step (3) and (4), until all initial sites required are selected.

The test sample set is IRIS data consisting of 150 samples of 4-D space samples which are divided into three categories, i.e. setosa, versiccolor and virginica each of which contains 50 samples whose 4 components are IRIS petal leangth, petal width, sepal length and sepal width. Of all the three types of samples, two overlap, one enjoys good distinction. The data is often used to test clustering algorithms and clustering validity function performance.

Table 1 Value of IRIS data with different values of m

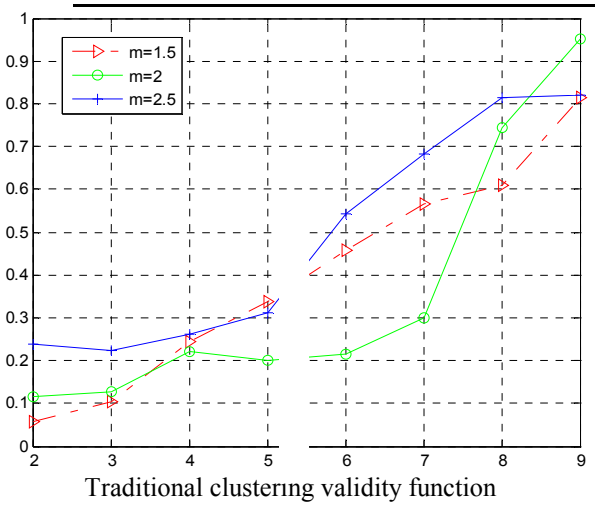

Fig. 1 Curve of changes of $H(U;c)$ with clustering number

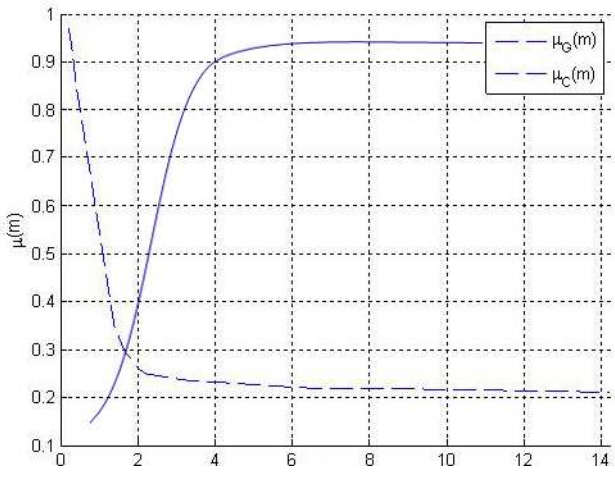

Fig. 2 m^* based on fuzzy decision-making method

The experimental results are shown in Table 1, and the results of clustering experiment for the function of entropy partition validity are taken good advantage of. Fig. 3 tells that when m=1.5 and m=2, $H(U;c)$ will show the optimal clustering number, but poor robustness of m is achieved. Fig. 1 and Fig. 2 demonstrate the distribution of local optimum clustering number corresponding to the weighted index with this method. Fig. 1 clearly shows that the membership function of fuzzy

objectives and fuzzy constraints intersect when $m = 1.8$, the weighted index in the intersection corresponding to the maximum membership in the intersection of fuzzy objectives and fuzzy constraints is 1.8, so optimal weighted index of clustering algorithm $m^* = 1.8$, close to $m = 2$ commonly adopted in FCM algorithm; Fig.2 shows the optimal weighted index m^* correspondence with $c_m^* = 2$, and classification result is in consistent with actual sample data distribution, i.e. the optimal clustering number $c^* = 2$. Therefore, the clustering algorithm proposed in this study can better realize the optimal weighted value and the optimal clustering numbering than traditional partition entropy validity function.

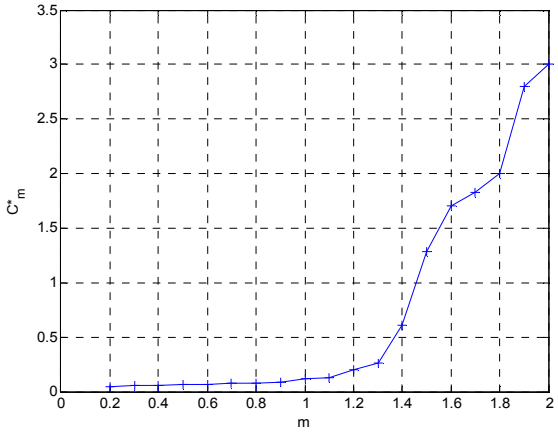

Fig 3 Curve of changes of c_m^* with different m

5. Conclusions

This paper, in view of the actual demand of civil aviation radar intelligence data, puts forward a fuzzy clustering algorithm based on weighted index and optimization of clustering number, and the experimental results show the superiority of this new algorithm to traditional fuzzy clustering algorithm, since it uses a method to gain m based on fuzzy decision-making method and validity index V_{kwon} based on concrete data set geometry structure to determine clustering number c^*, followed by realization of key parameters in FCM algorithm, namely, the selection of optimal weighted index helps to get the best clustering number, thus manual parameters selection in traditional algorithm is eliminated, and the local optimum of algorithm is avoided.

Keywords: Critical technology, Centrality Analysis, Fuzzy comprehensive evaluation, Hybrid approach.

Abstract. There have been attempts to indentify critical technology from many alternative technologies. Accordingly, we can form an R&D policy effectively if we can forecast central technologies. Multi-criteria decision-making method and Centrality Analysis have been applied to the problem. However, these two approaches have some limitations. This study proposes a hybrid approach to identify critical technologies in a technology network which take full advantage of experts' experience in technology field and relationship between technologies at the same time. Fuzzy comprehensive evaluation and Centrality Analysis of node are used in the approach. A case study on hypothetical critical technology identification problem is used to illustrate the proposed approach.

Introduction

The characteristics of modern technology can be defined as complexity, interdependence and radical. Under this uncertain and rapidly changing environment, the grasping of technological trend and development by analyzing overall structure of technologies and interaction among them has become much more important[1]. With some exercises to identify future key technologies, industry and government can manage R&D portfolio efficiently thus competitive advantage can be gained and sustained [2].

Critical technology identification is an unstructured, complex problem with lots of aspects that must be taken into consideration[3]. Different countries have developed different approach in identifying their critical technologies list[4,5,6]. Delphi survey[7], Technology Roadmapping[8], and some other technology foresight approaches[9] have been developed. Most of these critical or key technology studies are based on interviews with experts on the technology for which a forecast is being developed[4]. Typical critical technology identification exercise usually has four steps, including location and selection of experts, initial list of technologies, prioritization, final list of critical technologies[6]. Multi-criteria decision-making methods[9,10] are applied in prioritization to select criteria and integrate experts' judgment of technologies.

However, these studies do not pay much attention to the relationship and linkages between technologies. Assuming that, technology is a dependent variable, which may lead to unreasonable results. Furthermore, these approaches are much dependent on experts' experience, which is unquantifiable and sometimes subjective.

Since technologies are characterized by strong interdependence[11], there have often been attempts to examine technological structure and linkage as a form of network[11,12,13,14]. Network analysis has often been used in conjunction with patent citation analysis[15]. A number of studies have been conducted to frame current technology structure and identify Critical technology by using patent analysis, such as Cross Impact Analysis[1], co-word[16], and keyword vector similarity[17]. The underlying assumption in these studies is that there exists a technological linkage between the two patents if a patent cites another patent[1].As a quantitative measure of importance in a network, centrality measures of node can be used in network analysis. As defined by Freeman[18], degree centrality, closeness centrality and betweenness centrality have been employed as indicators of importance of certain nodes in networks. In the previous studies, these centrality measures have been implicitly deployed as indicators of importance of technologies [11].

Patent citation-based critical technology identification do has its limitation yet[1], it excessively relies on the analysis of network, which can only provide information about the network structure. Information and the value of technology nodes are ignored.

In this article, in order to overcome the weakness of traditional critical technology identification approach and Patent citation-based analysis, taking full advantage of experts' experience in technology field and relationship between technologies at the same time, we propose a new hybrid approach, integrating Fuzzy comprehensive evaluation and Network analysis to identification critical technology.

The remainder of this paper is organized as follows. Section 2 deals with the detail explain of the proposed approach and a brief introduction of Fuzzy comprehensive evaluation and centrality measures in network analysis, which will be used in the proposed approach. A hypothetical core technology identification problem which designed to demonstrate the algorithm is explained in Section 3. Section 4 is a conclusion of the paper.

Hybrid Approach For Critical Technology Identification

This study proposes a hybrid approach,which integrating Fuzzy comprehensive evaluation and centrality analysis to engage the challenge of critical technology identification. Fuzzy comprehensive evaluation is used to evaluate the alternative technologies against the set of criteria previously identified by experts' judgments, which will mark technologies with the experts' knowledge of technology fields. The node centrality analysis of technology network gives us information based on the structure of technology linkages. Then, we integrate evaluation results of Fuzzy comprehensive evaluation and centrality analysis and give the final rank of alternative technologies.

This critical technology identification process includes seven steps, a schematic diagram of the process is shown in Fig1.

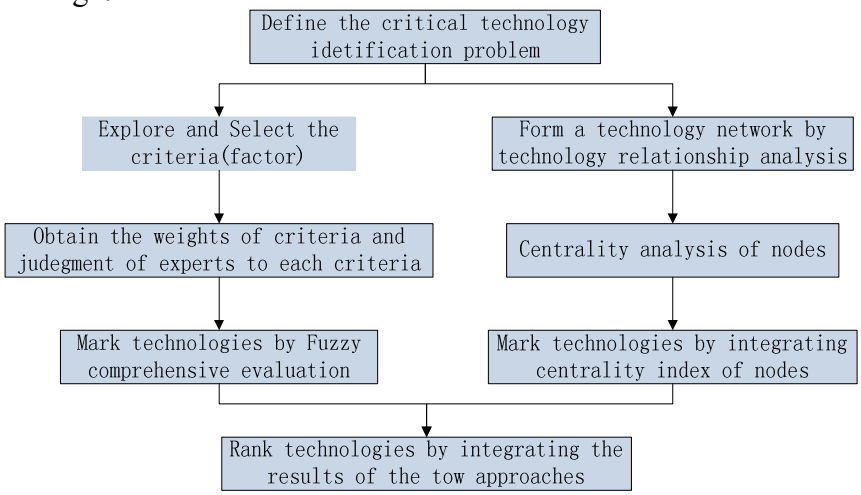

Fig 1. Hybrid approach for critical technology identification

(1) Define the critical technology identification problem. Identify the scope for which technologies will be analyzed.

(2) Explore the critical technology identification criteria (factor), such as benefit, cost, risk, and so on. Select criteria which will be used in the process. Suppose Factor(criteria) Set is $U = \{u_1, u_2, ..., u_m\}$. It is composed of m kinds of evaluation factors which decision-makers care. Evaluation Set is $V = \{v_1, v_2, ..., v_n\}$. It represents n kinds of evaluation standards.

(3) Obtain the weights of criteria and judgment of experts to each criteria from different backgrounds. For Fuzzy comprehensive evaluation, Evaluation factors(criteria) weight vector is $E = \{e_1, e_2, ..., e_m\}$, Single-factor evaluation matrix R is constituted by numbers of single-factor evaluation vector put together. R is a fuzzy relationship matrix composed of evaluation Factor Set U and the Evaluation Set V.

$$R=\begin{bmatrix} R_1 \\ R_2 \\ \vdots \\ R_m \end{bmatrix}=\begin{bmatrix} r_{11} & r_{12} & \cdots & r_{1n} \\ r_{21} & r_{22} & \cdots & r_{2n} \\ \vdots & \vdots & & \vdots \\ r_{m1} & r_{m2} & \cdots & r_{mn} \end{bmatrix} \tag{1}$$

(4) Mark the technology options by Fuzzy comprehensive evaluation result. The last results of comprehensive evaluation can be got by doing complex operations calculation between single factor weight vector E and fuzzy relationship matrix R, which is as follows.

$$B=E\bullet R=\{b_1,b_2,\ldots,b_m\} \tag{2}$$

b_i is the membership degree value of evaluation samples to each evaluation standard. The determination results are usually defined according to the maximum membership degree law.

In this article, the best judgment($B_i^{'}$) of b_i is selected as the initial score of technology, it represents the critical analysis based on experts' experience. Then, we normalize the initial score of each technology, Calculation formula of final score B_i is shown in (3).

$$B_i=\frac{B_i^{'}}{\sum_{i=1}^{i=10} B_i^{'}} \tag{3}$$

Step 2 to step 4 is Fuzzy comprehensive evaluation approach, Fuzzy comprehensive evaluation approach is a very effective and wide used multi-criteria decision making method, papers[19,20] will give more details about the Fuzzy comprehensive evaluation approach. In this study, it is used to rank the technology alternatives by experts' judgment with multi-criteria.

(5) Form a technology network by analysis relationship between technologies such as patent, key works, and so on.

(6) Centrality Analysis of nodes in the technology network.

To characterize individual technology's positions in a technology network, various centrality measures of node can be calculated. Three common measures of node centrality, degree centrality, closenees centrality and betweenness centrality[18] are choosed in this study. These three measure indexes are referenced to different structural attributes of technology.

Degree centrality($\sigma_D(x)$)[21] was defined as the number of ties incident upon a node. It represents the simplest centrality measure and determines the number of direct contacts as an indicator of the quality of a network member's interconnectedness.The higher $\sigma_D(x)$ for a node x is, the more contacts a node x has, and the more inportant the node is. For technology network, it means the higher centrality score $\sigma_D(x)$ for a technology node is, the more neighbor it has, and the more important the technogy is.

Closeness centrality ($\sigma_C(x)$)[21] is based on the idea that nodes with a short distance to other nodes can spread information very productively through the network. In order to calculate $\sigma_C(x)$ of a node x, the distances between the node x and all other nodes of the network are summed up. For technology network, technology with smaller $\sigma_C(x)$ is closer to the center of technology network and can spread information smoothly to other technologies, and the technology is much more critical.

Betweenness Centrality($\sigma_B(x)$)[21] is based upon the frequency with which node falls between pairs of other nodes on the shortest or geodesic paths connecting them, it is used to exhibit a potential for control of the communication. For technology network, technologies with higher σ_B play much more important role in the exchange of information between other technologies.

Papers[22,23] may give you more information about the definition and detail calculation process of these node centrality.

(7) Mark the alternative technologies by integrating centrality index of nodes. In order to integrate the result of node Centrality Analysis, we define the integrating centrality index($\boldsymbol{ICI_i'}$) which is shown in formula (4).

$$ICI_i' = \frac{Degress * Betweenness}{Closeness} = \frac{\sigma_D(x) \bullet \sigma_B(x)}{\sigma_C(x)} \tag{4}$$

(5) is the formula of the normalized $\boldsymbol{ICI_i'}$ ($\boldsymbol{ICI_i}$) for each technology.

$$ICI_i = \frac{ICI_i'}{\sum_{i=1}^{i=10} ICI_i'} \tag{5}$$

(8) Integrate the results of Fuzzy comprehensive evaluation and node Centrality Analysis, get the final rank of alternatives.Final critical index (***CI***) is defined to integrate the results of Fuzzy comprehensive evaluation and Centrality Analysis of technology node. Critical technology is identified based on the final critical index. For each technology, calculation formula of CI_i is (6).

$$CI_i = B_i + ICI_i \tag{6}$$

In this hybrid approach, Fuzzy comprehensive evaluation gather the knowledge from experts in the technology field, Centrality Analysis based on the linkage and interaction between technologies, the two approaches is integrated in the hope of entailing a more objective and practical critical technology identification process.

Illustrative example

A hypothetical critical technology identification problem was designed to demonstrate the computational process of the algorithm.

Step1. Define the critical technology identification problem. The problem is to identify a critical technology in a technology network. Committee of experts who come from different technology fields is formed. After a discussion, experts have identified 10 technologies from T_1 to T_{10} and the technology network is constructed for evaluation.

Step2. In order to simplify the algorithm of Fuzzy comprehensive evaluation process, only three criteria (factor) are being considered which are as the following:

1) Advance(C_1)
2) Technology Readiness Level(C_2)
3) Cost(C_3)

Step3. A set of linguistic scale, such as 'high, average, low' is used to evaluate the importance of the criteria and sub-criteria. Weights for selection criteria (C_1, C_2, C_3) is (0.2, 0.3, 0.5) and the judgment of experts to each sub-criteria is shown in Table 1.

Step4. For the paper limitation, we will neglect the detail calculate process and only give the result of Fuzzy comprehensive evaluation.

Table 1.Judgment of experts to each sub-criteria

Judegment	Advance (C_1)			Technology Readiness Level (C_2)			Cost (C_3)		
Technology	advanced	general	backward	high	average	low	expensive	common	cheap
T1	0.7	0.2	0.1	0.1	0.2	0.7	0.3	0.6	0.1
T2	0.3	0.6	0.1	1	0	0	0.7	0.3	0
T3	0.1	0.4	0.5	1	0	0	0.1	0.3	0.6
T4	0.6	0.4	0	0.7	0.2	0.1	0.4	0.6	0
T5	0.4	0.5	0.1	0.3	0.6	0.1	0.8	0.1	0.1
T6	0.2	0.6	0.2	0.7	0.3	0	0.2	0.8	0
T7	0.5	0.3	0.2	0.3	0.5	0.2	0.5	0.4	0.1
T8	0.9	0.1	0	0.4	0.6	0	0.8	0.2	0
T9	1	0	0	0.3	0.4	0.3	1	0	0
T10	0.7	0.3	0	0.5	0.4	0.1	0.6	0.4	0

For each technology, the results of Fuzzy comprehensive evaluation are $\boldsymbol{B_1}$ = (0.27, 0.46, 0.27), $\boldsymbol{B_2}$ = (0.56, 0.33, 0.11), $\boldsymbol{B_3}$ = (0.27, 0.27, 0.46), $\boldsymbol{B_4}$ = (0.4, 0.5, 0.1), $\boldsymbol{B_5}$ = (0.56, 0.33, 0.11), $\boldsymbol{B_6}$ = (0.3, 0.5, 0.2), $\boldsymbol{B_7}$ = (0.45, 0.36, 0.18), $\boldsymbol{B_8}$ = (0.625, 0.375, 0), $\boldsymbol{B_9}$ = (0.45, 0.27, 0.27), $\boldsymbol{B_{10}}$ = (0.5, 0.4, 0.1). Best judgment is selected as the initial score of each technology. For example, 0.27 is selected as the initial score of technology 1. Then, we normalize the score of each technology, the initial score ($B_i^{'}$) and final score (B_i) for each technology are shown in Table 2.

Table 2. Initial and final score for each technology

	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10
$B_i^{'}$	0.27	0.56	0.27	0.4	0.56	0.3	0.45	0.625	0.45	0.5
B_i	0.062	0.128	0.062	0.091	0.128	0.068	0.103	0.143	0.103	0.114

Step5. We simplify relationship between technologies such as patent citation, keyword similarity. There is only a connection if technology1 and technology 2 is related. The technology network we formed is in Fig 2.

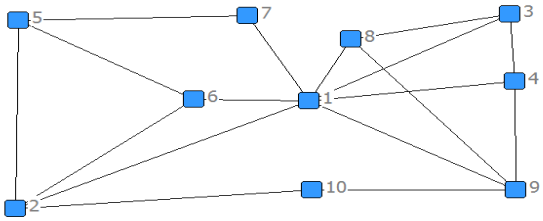

Fig 2. Technology network

Step6. Centrality analysis of nodes in the technology network. The Degree, Betweenness and Closeness centrality of each node are calculated by Ucinet software. Results of Node Centrality is shown in Table 3.

Table 3. Results of Node Centrality

	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10
Degree	7	4	4	3	3	3	3	3	2	2
Betweenness	18.08	5.25	3.92	1.58	1.58	1.33	0.75	0.58	0.58	0.33
Closeness	11	14	15	15	16	16	17	17	18	19

Step7. Calculate the integrating centrality index (***ICI***) of nodes. Results of integrating centrality index and the normalized $\boldsymbol{ICI_i^{'}}$ of each technology is shown in Table 4.

Table 4. Results of integrating centrality index

	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10
$ICI_i^{'}$	11.51	1.5	1.05	0.32	0.30	0.25	0.13	0.10	0.06	0.03
ICI_i	0.755	0.098	0.069	0.021	0.020	0.016	0.009	0.007	0.004	0.002

Step8. The final critical index (***CI***) integrate the results of Fuzzy comprehensive evaluation and Node centrality analysis. Table 5 is the final critical index for each technology.

Table 5. critical index for each technology

	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10
CI_i	0.817	0.226	0.197	0.112	0.148	0.084	0.112	0.15	0.107	0.116
Rank	1	2	3	6	4	7	6	8	9	5

Critical technology is selected based on the rank of final critical index. In this illustrative case, Technology 1 should selected as the critical technology since it has the highest critical index.

Summary

This study suggests a hybrid approach to identify critical technology in a technology network. For this purpose, Fuzzy Comprehensive Evaluation Method is used to gather the knowledge from experts in the technology field, Centrality Analysis of nodes, which based on the linkage and interaction between technologies prioritize technologies by objective structure information. We integrate these two types of approaches to get the final rank of technologies. To illustrate the process of executing and utilizing the proposed approach, a hypothetical critical technology identification problem is presented.

The main contribution of this study is that, experts' experience and technology network analysis was integrated together in the hybrid approach, which will take full advantage of technology related information and have a more comprehensive and practical identification process.This study, however, is still subject to some limitations and these limitations are issues for further research. Centrality Analysis of nodes doesn't get adequate information of technology network, and the two approaches which we used need some improvement if there is a large number of technologies in the technology network.

Keywords: Sentiment dictionary; SVM classifier; Text orientation analysis;

Abstract. Sentiment classification finds various applications in opinion mining, which can help users determine sentiment tendency of texts and information. In this paper, we consider the problem of text orientation analysis. In particular, we propose a two-stage approach by coupling sentiment dictionary and classification methods. In the first stage, we build sentiment dictionary and rules to obtain the texts whose emotional scores are ranked in the top 1/4 and the bottom 1/4. These texts are marked classified for supervising the second stage. In the second stage, we employ the SVM classifier to process the remaining texts. Finally, we combine the two stages to get the orientation analysis results for all the texts. Experimental results demonstrate that, in contrast to using sentiment dictionary and classification method separately, our proposed method achieves higher classification accuracy when an initial training set by manual tagging is unavailable.

Introduction

With the rapid development of Web technology, the Web has become a very important source from which more and more people obtain information. Mining and analyzing the rapidly expanding texts on web, especially the sentiment of the online reviews posted by users, can make people better understanding of the consuming habits and public opinions of various users. Besides, it plays an important role in decision-making for many institutions, such as enterprises, the government, etc. Therefore, it is very significant to study the sentiment classification problem about online comments. However, the massive amount of information is widely distributed online, it is difficult to collect and process them without manual means. Thus the sentiment classification technology arose. At present, the research of text orientation analysis is generally divided into two categories in domestic and abroad: the method based on sentiment dictionary or machine learning.

Although sentiment dictionary method and machine learning method are relatively mature, there exist some flaws. On one hand, the method based on sentiment dictionary is not a good way to classify text which is obscure. On the other hand, machine learning method requires a large set of manually annotated text, which is difficult to achieve. Therefore, depending on many basic studies, combining the advantages of both methods above, we propose a two-stage classification approach to solve the problem.

Related Work

The method based on sentiment dictionary uses a dictionary which is marked emotional polarity to calculate emotional polarity of the text. While the method based on machine learning regards sentiment classification as a special kind of text classification which uses manually labeled training set and the method of machine learning to classify texts. For the texts to be classified, word segmentation and removing stop words should be implemented firstly.

The Method of Sentiment Dictionary

The priority work of sentiment dictionary is building up the appropriate sentiment thesaurus. General Inquirer (GI) and WordNet are used as commonly basic resources to study English text sentiment classification. While in Chinese text sentiment classification study, HowNet is more widely used, it is necessary to choose sentiment dictionary according to actual needs. After establishing the sentiment dictionary, take advantage of existing tools to deal with language

materials which is prepared by syntactic analysis, dependency analysis, etc. Extracting the modifiers of the sentiment words combined with sentiment words tendencies value. According to certain algorithm, the phrase sentiment tendency of the sentence is calculated and then the sum of the tendencies value of these phrase containing sentiment words is weighted. At last, obtain the sentiment tendencies value of the entire text by summing to achieve the purpose of sentiment analysis.

The Method of Machine Learning

Machine learning method mainly consists of the training process and the classification process. First of all, set training set that is classified manually, using frequency as a statistic to calculate the distribution of category entries in the text. Due to the problems of high-dimensional feature space and documentation sparse vectors, it is necessary to find a good feature selection method. Through feature selection method we can get some key features which are representative. Then according to the calculation method of Term Frequency Inverse Document Frequency(TF－IDF) [1],we can calculate the weight of each key feature and quantify them and then get Vector Space Model (VSM) [2]. In the next classification process, dealing with the test text by the same operation as described above. Finally, choose the appropriate classification algorithm to classify, calculating the similarity between test text vector and category vector which have been trained. The category which has the largest similarity value will be the final classification of the text to be measured.

The Two-stage Text Classification Method

Building the Rules of Sentiment Dictionary

In order to build the sentiment dictionary, we use *sentiment analysis using word set* released by HowNet and network language manually collected. For sentiment words, the negative words invert its emotional polarity, while the degree adverbs strengthen or weaken its emotional polarity. So we should construct emotional words (S) dictionary, negative words (N) dictionary and degree adverbs (D) dictionary, manually annotate emotional polarity value of sentiment words and degree polarity value of adverbs, then building rules to determine the emotional polarity of the texts.

In addition, we should take into account of the effect of dynamic sentiment words. The words called dynamic sentiment words have different tendencies when modifying different target words. Such as the sentiment word "high", when the target word is quality, it tends to positive, but when the target word is oil consumption, it tends to negative. In dealing with the word, we should create a dynamic sentiment dictionary, including dynamic sentiment words and matching words. DSW represent the set of dynamic sentiment words, divided into forward sets denoted as FDSW and backward sets denoted as BDSW. PW is the set of matching words near sentiment words, also divided into forward sets denoted as FPW and backward sets denoted as BPW. dt is a dynamic sentiment word, dp is a matching word, wp_f is the emotional polarity value when dynamic sentiment word's matching word belongs to FPW, wp_d is the polarity value of the composition, calculated as follows:

$$C(dt)=\begin{cases}1 & if\ dt\in FDSW\\ -1 & if\ dt\in BDSW\end{cases} \quad (1) \qquad C(dp)=\begin{cases}1 & if\ dp\in FPW\\ -1 & if\ dp\in BPW\end{cases} \quad (2)$$

$$wp_d = wp_f * C(dt) * C(dp) \quad (3)$$

After we find the dynamic sentiment word phrase, regarding the whole phrase as another sentiment word, and then deal with negative words and degree adverbs. p_d is the emotional polarity value of the phrase, wp_d is the emotional polarity value of sentiment words, d_d is the degree polarity value of adverbs. For different syntactic structures, emotional polarity calculation methods are different. As shown in Table 1:

Table 1. Emotional polarity calculation method

Syntactic structure	Emotional polarity calculation formula
S+D/D+S	$p_d = wp_d * d_d$ (4)
N+S	$p_d = (-1) * wp_d$ (5)

N+D+S	$p_d = d_d * wp_d$ (6)
D+N+S	$p_d = (-1) * d_d * wp_d$ (7)

Calculating emotional scores of each phrase of the text according to the syntactic structure in order to accumulate and get the whole sentence emotional score. i is number of sentence, P_{ij} is the emotional score of phrase j in sentence i. In order to eliminate the influence of text length on the final emotional score, the sum of the scores should be divided by the number of sentence. If the final emotional polarity value P of the text is greater than zero, the comment is positive otherwise is a negative comment. Calculated as follows: $P = \frac{\sum P_{ij}}{i}$ (8)

Feature Selection Method

The commonly feature selection methods are Document Frequency (DF), Information Gain (IG), Mutual Information (MI) and Chi-square Statistic (CHI), all these feature selection methods have its own advantages and disadvantages. For their shortcomings, we propose an improved feature selection method IDTC, use two indicators including the probability of the appearance of features and the correlation of features and categories to calculate the information value of features for the category. What different with DF which rely on the document frequency directly is the improved feature selection method uses the probability of the appearance of features to substitute features frequency, and combines the method of MI to represent the correlation of features and categories meanwhile. For a second-class relationship, we can calculate the information difference of the two categories that reflect the discrimination of characteristics to these two categories. The formula is defined as: $IDTC(t_i, C_j, C_k) = P(t_i) * |MI(t_i, C_j) - MI(t_i, C_k)|$ (9)

$P(t_i)$ is the probability of features appearing, $|MI(t_i, C_j) - MI(t_i, C_k)|$ represents the ability of features to distinguish between the two categories. During feature selection process, we remove the features below a given threshold from the original feature space, and retain the features above the threshold as representative features of the document.

Support Vector Machine

Support Vector Machine (SVM) is a traditional classification method and it has outstanding performance for classification [3]. Let us assume that a training set consists of N labeled samples $(x_i, y_i)_{i=1}^N$, where $x_i \in R^d$ denotes the training samples and $y_i \in \{-1, +1\}$ denotes the associated labels. The goal of a binary SVM is to find out a hyperplane that separates the dimensional feature space into two subspaces. An interesting feature of SVM is relative to the possibility to project the original data into a higher dimensional feature space via a kernel function $K(,.,)$, which satisfies the Mercer conditions [4]. SVM is a classification method designed for binary class issues [5], the purpose of text orientation analysis is based on the document feature vector to divide the document into positive and negative category, so we choose SVM in machine learning stage in this paper.

The Two-stage Classification Algorithm Process

Text classification based on two-stage experimental process is describes as the following steps:

1) Step1: Text preprocessing. Making preprocessing operations such as word segmentation and removing stop words.

2) Step2: Sentiment tendencies calculation. We can read all the texts in text files. By the method of sentiment dictionary, calculating the emotional scores of all the texts.

3) Step3: Text score sorting. As all the texts sorted by scores, we can get the texts which have clear emotional polarity. The texts which scores ranked in the top 1/4 and the bottom 1/4 are chose as the classified collection of the second stage to train, and the texts which scores ranked in the middle 1/2 are chose as unclassified collection of the second stage to test.

4) Step4: Feature selection. The improved feature selection method IDTC extracts feature words in classified and unclassified collection separately.

5) Step5: Text vector representation. The weight of each selected feature calculated by TF-IDF method, and then we can get the Vector Space Model.

6) Step6: SVM classifier for classification. To classify the unclassified texts, we choose SVM classification algorithm.
7) Step7: Get the experimental results.
Fig.1 shows the two-stage classification algorithm process.

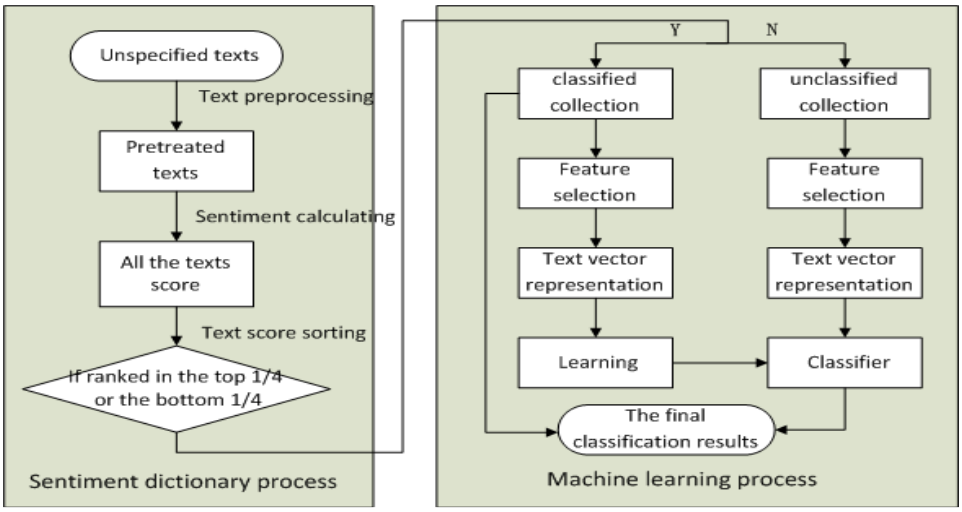

Fig.1 The two-stage classification algorithm process

Experiment and Results Analysis

Experiment Setup

The algorithm was implemented in Java. We used the segmentation system ICTCLAS designed by Institute of Computing Technology, Chinese Academy of Sciences to achieve word segmentation, and adopted a SVM tool named LibSVM by Taiwan University to implement the SVM classification model. The experimental data sets were obtained from the authors of [6] that included Ctrip_htl_4000 (4, 000 hotel comments), Dangdang_Book_4000 (4, 000 book comments) and Jingdong_NB_4000 (4, 000 laptop comments). Each of the three data sets has 2, 000 positive comments and 2, 000 negative comments, respectively.

Analysis of the Results

For each data sets, in order to prove the validity of the proposed method, we all chose 2000 texts as training sets, and another 2000 texts as testing sets. First of all, we classified the testing sets by machine learning method, mainly applied the improved feature selection method and SVM classifier. Next, the same testing sets were classified by sentiment dictionary method. At last, we used the two-stage text classification method to run the same experiment. In particular, we selected the testing sets whose emotional scores were ranked in the top 500 and the bottom 500 as the classified collection of the second stage for training, and then classified the texts score ranked in the middle 1000 by SVM classification. We utilized the Macro-Precision (P), Macro-Recall (R) and Macro-Fscore (F1) [7] to evaluate the performance in average, and chose F1 as the final evaluation index, where F1 is defined as:

$$F1=\frac{2RP}{(R+P)} \quad (10)$$

Classification results are shown in Table 2. In feature selection process, we selected 1000 features ranked in the top.

Table 2. Classification results

The Dataset	Sentiment Dictionary	Machine Learning	The Combined Method
Ctrip_htl_4000	0.794631	0.814810	0.825407
Dangdang_Book_4000	0.808524	0.864639	0.880730
Jingdong_NB_4000	0.812507	0.830068	0.842816

As shown in experimental results, for all of the three data sets, when we use sentiment dictionary method independently, the classification accuracy is near 80%, and machine learning method is

superior to sentiment dictionary method in classification accuracy, while the classification accuracy is further improved by our two-stage approach combined with sentiment dictionary and classification methods. Also we can see that the performance of the classification of book comments is better than the other two. Next, we evaluate the effect of the number of features, and provide the results in Fig. 2.

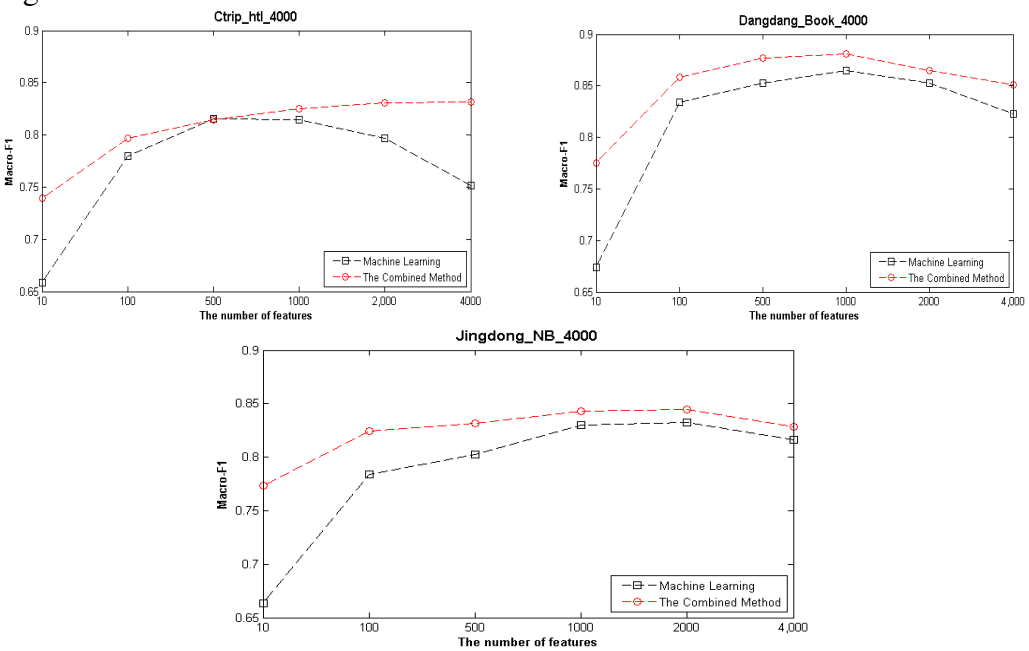

Fig.2 The effect of the number of features

As in Fig.2, horizontal axis represents the number of features, where features are ranked in descending order of weight, and high-ranking features are preferred; vertical axis represents the value of Macro-F1 when selecting the features ranked in the top.

Using machine learning method independently, the classification performance is gradually improved with the growth of the number of selected features. While after the number of features item reaches a certain number (about 1000), the rating trend begins to decline. The method of the two-stage classification shows that the classification accuracy increases slowly with the growth of the number of features. We are glad to see that the classification accuracy of the combined method is still higher than machine learning method on the condition of the same number of features.

Conclusions

This paper proposed a two-stage text classification method based on combining the methods of sentiment dictionary and SVM classification. Experimental results show that compared with the sentiment dictionary method or the classification method, the proposed two-stage method can achieve higher accuracy. As future work, we plan to further investigate the construction of domain sentiment dictionary and grammar rules, since it is the prerequisite for generating unclassified texts, and it involves a number of issues such as the discovery of new words.

RESEARCH ON THE OPTIMIZATION OF THE STORAGE STRATEGY OF HDFS

Hui Cao

Henan Radio and Television University, Zhengzhou 450008, China

402793927@qq.com

Keywords: optimization, storage strategy, HDFS.

Abstract. The storage of the massive data puts forward higher requirements in quantity and quality of hardware so that the cost of hardware rises. We have to use software for weakening the requirements of hardware. HDFS is just born for solving the massive data storage. Through the analysis of the files of the organization, storage mode, storage technology etc. this paper presents the optimization of data storage strategy of HDFS and the description of the optimization algorithm.

Introduction

Cloud computing is the development [1] of Distributed Computing, Parallel Computing [2] and Grid Computing [3]. Cloud storage is a new concept on the extension and development of cloud computing.

Cloud storage, as a system that provides the functions of data storage and business access, adopts applications to let the large variety of storage devices of different types work together through the functions of cluster applications, grid computing, distributed file system and so on.

The rise of cloud storage is to subvert the existing network storage architecture. With the development of information technology and internet [4], the amount of data on the network is more and more big, the users demand the storage businesses with higher reliability and safety, the business types also becomes richer, there is little the existing storage can do. For example, there is a performance bottleneck with traditional NAS[5] or SAN[6] in capability and capacity expansion, when the client business requirements can not be met, the enterprise must upgrade to the storage system more or add more management tool, and increases capital investment. Cloud storage service mode not only breaks through the bottleneck of traditional SAN, but also can expand the capacity and performance linearly, that is a new choice for the enterprise which pursues high availability and high performance.

Hadoop distributed file system is called HDFS for short, it is designed as distributed file system which is suitable for running on commodity hardware. HDFS is a highly fault tolerant system and suitable for deployment in cheap machine. HDFS can provide access to high throughput data, is very suitable for large data sets.

File organization of the HDFS

HDFS is a distributed file system which has the characteristics of high fault tolerance and is designed to be deployed in the low cost of hardware equipment. In HDFS, file exists in the form of block data and the data block size can be set, default is 64M, which is more than the general operating system file blocks to be big.

File storage mode of the HDFS

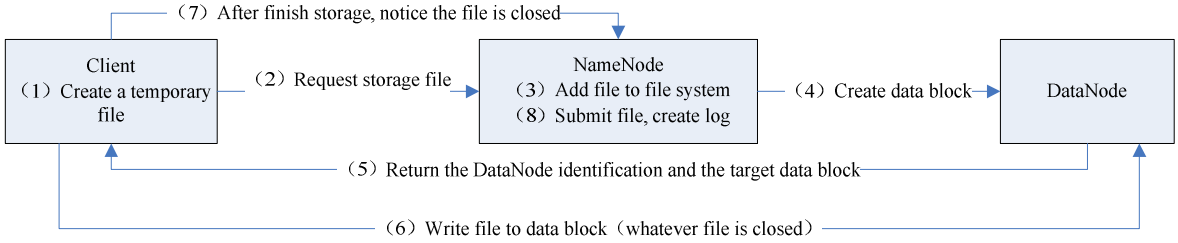

Fig. 1 Storage process in HDFS

When a client needs to store files, storage process in HDFS is pictured above (Fig. 1).

(1) The client creates a temporary file in the local at first. The operating of write is based on the temporary file.

(2) The client requests storage file to the NameNode.

(3) The NameNode adds the file to the file system.

(4) The NameNode sends the request of creating the data block to the DataNode.

(5) The DataNode returns the DataNode ID and the target data block to the client.

(6) The client file is writed to the data block. During the execution of a write operation, the client closes the file, does not affect the file write.

(7) When file storage is completed, the client notice the NameNode that the file is closed.

(8) The NameNode submits the log of creating file to the transaction log.

Storage technology of the HDFS

Fault-tolerant mechanism in HDFS: HDFS creates three copies by default for each data block. The first copy is set on a node in the local rack. The second copy is set on the other node in the same rack with the first one. The third copy is set on a node in different rack.

There are two kinds of common mistakes in the process of file storage in HDFS. One is node failure, the other is data corruption.

The node failure mainly refers to the DataNode failure because of the network partitions. The DataNodes periodically send heartbeat message to the NameNode, on the one hand, if the NameNode dose not receive the message from the DataNodes during the stipulated time, the DataNode is believed to be out of order and it is labled as dead node, on the other hand, the NameNode continually detects the shortage of data copies because of the dead node, and start the copy mechanism.

The data corruption refers that the data is damaged which is read from the DataNode. HDFS adopt the checksum file to detect the data integrity. The checksum file is generated when the client creates the file, which saves the checksum of all data blocks from new file. When the client reads the file, the checksum of file will be compared with the checksum saved in the checksum file, if the two are same, the data are complete, else read other data block copy.

Balance in HDFS: Balance in HDFS refers that the file blocks distribute well in every node of the cluster. The distribution of the file blocks is a dynamic process, HDFS offers the balancer tool to make sure the storage balance.

Optimal storage strategy

Fault checked and recovery ability which is automatic and fast are the core targets of HDFS. Heartbeat mechanism realizes detecting the fault node. This paper offers using this mechanism to statistic the reliability of the nodes so that filtering the DataNodes before writing files, and realizing the change from passive detection after failure to active screening before using the nodes.

Algorithm description of the optimal storage strategy

This paper gives the general algorithms for the storage of the data blocks based on the optimal strategy (Fig.2).

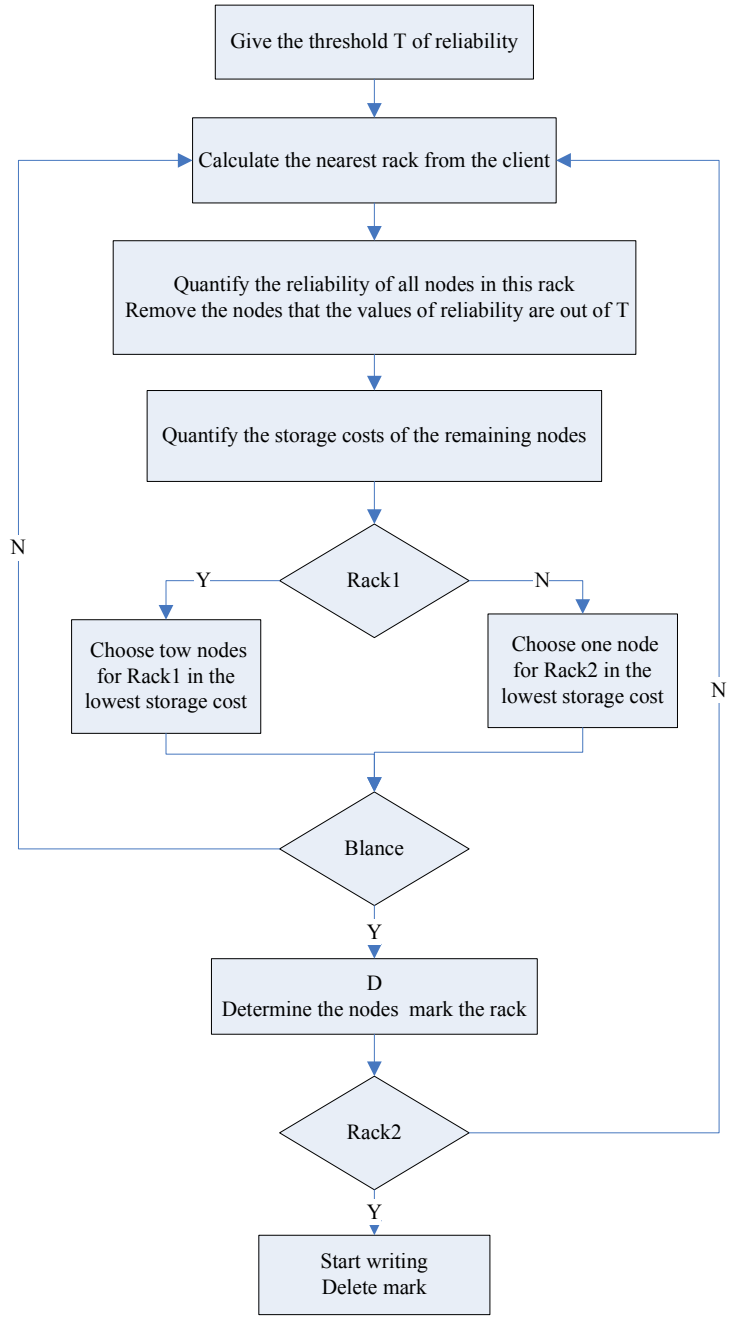

Fig.2 Algorithm flow

Firstly, the NameNode gives the threshold T of reliability according to the needs of users and the characters of data.

Secondly, the NameNode calculates the nearest rack from the client.

Thirdly, quantify the reliability of all nodes in this rack and remove the nodes that the values of reliability are out of T.

Fourthly, quantify the storage costs of the remaining nodes.

Fifthly, we define the rack which is used to storage two copies as Rack1 and define the one which is used to storage one copy as Rack2. Judge whether or not the rack which chooses from the secondary step is labeled as Rack1, if not, it will be dealt as Rack1, otherwise as Rack2. Choose tow nodes for Rack1 or one node for Rack2 that in the lowest storage cost.

Sixthly, judge whether or not the cluster is in balance, determine the nodes and mark the rack when the cluster is in balance, otherwise recalculate the rack and choose the nodes again.

Seventhly, if Rack2 is marked, start the operation of writing data and deleting the name of the rack, otherwise recalculate the rack and choose the nodes again.

Conclusion

Through the research of the file organization, storage mode, storage technology etc. in HDFS, this paper describes the optimization of the strategy and the algorithm flow of the optimization. In the future research work, the calculation methods of the reliable value and choice cost of the DataNode need further improvement.

Research on packet encryption algorithm in the cloud storage

Hui Cao

Henan Radio and Television University, Zhengzhou 450008, China

402793927@qq.com

Keywords: cloud storage, packet encryption, data security.

Abstract. The storage and management of the huge data is solved by the cloud storage. The users can access the data whenever and wherever possibly in the cloud. The cloud storage provides convenient services for users. The problem of data security has been paid more and more attention at the same time. Based on the problems of the big data and the high repetition rate, this paper presents the improvement of the existing mainstream encryption algorithm. The algorithm can encrypt the same data, storied in different locations, into different ciphertexts, to make sure the data security in the case of the trusted cloud.

Introduction

With the rapid development of information technology and the Internet, People's daily work and life more and more use and rely on the network, resulting in massive data. The storage and management of the huge data is solved by the cloud storage. The users can access the data whenever and wherever possibly in the cloud. But, because of data breaches appeared frequently, the security problem of the cloud storage has become a hot issue cared by people in recent years.

In 2011, CSDN, the largest programmers' community at home, was attacked by the hacker, exposed by a micro-blog. As the world's largest Chinese IT technology community and china's largest programmers' community, the website of CSDN had 20 million registered users. Since the database leak of CSDN, parts of the user databases had been online for download including renren, mop, YY etc. and parts have been confirmed the authenticity. [1] This event and the chain events set off a discussion craze of the cloud computing security. With more and more users of the cloud computing, more data are stored in the cloud, and security issues have become increasingly important.

In 2013, the exposure of America National Security Agency (NSA) stealing the secret files rekindled the safety concerns about the data storied in the cloud. Data encryption is beginning to attract people's attention. However, enterprise users and cloud service providers to reform its internal security and privacy protection strategy, strengthen the cloud data security protection, is long overdue, but has not done. [2]

In 2013, Symantec and Ponemon Institute released the "2013 data disclosure cost analysis: global research report". The study data show that Data leakage accident 2/3 was caused by human error and system problems in 2012 and each damaged data record average cost up to $136 in global. The difference of global average cost of data reveal is significant. These differences are mostly because the type of risk faced by enterprises and different national data protection laws. Germany, Australia, Britain, USA and other countries has consumer protection laws and regulations more perfect to enhance data security and network security. Nevertheless, the data disclosure cost of America and German is still the highest (average accident costs were $188 and $199). The total cost of individual data leak in the two countries was the highest ($5400000 in America, $4800000 in Germany). [3]

Through in-depth study on the leakage accident, we found that the security industry obviously still have a lot of work to do. Valuable database still not under strict protection and encryption; there are still a large number of security vulnerabilities in application; users are still able to download a lot of information from the sensitive database and save it in the terminal which is lack of protection.

Whether the cloud storage services how powerful, the cloud storage can solve the security problem is always the determining element of the cloud storage life. Only the safe cloud storage can stimulate the user enthusiasm. Therefore, cloud storage security must get people's attention.

There are three main types of data protection are more applied in currently storage system: cipher technology [4], tamper-proofing technology [5] and backup redundancy technology [6]. They are applied to the needs of different storage security.

Mass data image illustrates the quantity of the huge data in the cloud storage and duplicate data is very prominent phenomenon. The same plaintext data encrypted with general block cipher produce the same ciphertext. Once the data is leaked, through statistical analysis and comparison of a large number of data, the risk of data decrypted is very big. This paper presents the improvement of the existing mainstream encryption algorithm. This algorithm can encrypt the same data storied in different locations to different ciphertext to make sure the data security in the case of credible cloud.

Problems to be solved by the algorithm

There are several problems should be solved by the algorithm.

(1) In the process of the common data transition, to avoid the plaintext data from being intercepted, the cloud should adopt MD5 security mechanism, calculate the MD5 value, encrypt and save the data uniformity.

(2) The data in the cloud storage is in large quantity and high repetition rate. The algorithm should be considered generating different ciphertext data from the same plaintext data so as to avoid the risk of data being stolen in the cloud and ensure the data security.

(3) To ensure the safety of the cloud storage system, the encryption algorithm should not only achieve the same plaintext to different ciphertext but also fall the whole group of ciphertext when any one changes.

(4) The basis of packet encryption mode is the mode of the data storied in the cloud. In the cloud, the data exist as blocks; the sector is the memory unit of the block and is also the unit of data read and write. The encryption algorithm should also use the sector as the basic unit of data, and ensure that multiple encryptions do not increase the length of ciphertext.

(5) The storage management of massive data demands on system performance very high. The algorithm design should ensure high computing efficiency and not take big deviation from the mainstream encryption algortithm.

(6) The particularity of the data process in the cloud storage put forward higher requirements on the efficiency of the algorithm. For efficient computation, the number of the key generation should reduce and the production time should be shorten. Only a fixed key can consider using.

Summary of the optimal algorithm

Based on AES algorithm, this paper designed the encryption algorithm with the 256 bits original key, 128 bits packet length and 13 ring blocks. Here is the general description of the algorithm.

First of all, there are tow kinds of key, the master key and the round key. Two kinds of key are placed in the cryptographic device after the system initialization is complete.

Secondly, calculate the block number of the packet and complete the initial vector selection. Because of different block number of each packet, on the basic premise of using the same master key, the initial vector of each packet are also different.

Thirdly, achieve the encryption operation of 512 byte plaintext. 512 byte plaintext is divided into 32 packets. Encryption operation is really on 32 packets plaintext. There are tow steps of encryption process: first step, take advantage of the initial vector which is selected, use first 6 rounds in CBC mode to encrypt 32 packets plaintext, obtain 32 packets ciphertext; second step, choose the last vector obtained in step one as the initial vector, adapt the last 7 rounds in CBC mode to encrypt the ciphertext obtained in step one, achieve final 32 rounds ciphertext.

Fourthly, achieve the decryption operation of 512 byte ciphertext. Decryption is the inverse process of encryption operation, is also divided into two steps: first step, take advantage of the initial vector used in step two of encryption process, adapt the last 7 rounds in CBC mode to decrypt the ciphertext first time; second step, use the initial vector chose in step one of encryption process, adapt the first 6 rounds in CBC mode to decryption the ciphertext second time and get the plaintext.

Conclusion

Based on the above description, the algorithm proposed in this paper has the following three features:

(1) The algorithm adapt the initial vector to AES encryption calculation which is not in the traditional AES algorithm.

(2) The algorithm uses the CBC mode twice which is two times than traditional encryption calculation. The efficiency of the algorithm has been little affected and the increase is just the XOR operation, therefore, the impact is negligible.

(3) According to the different locations of the storied data, the initial vector is also different in the algorithm so as to avoid generating the same ciphertext from the same plaintext and ensure data security.

This algorithm achieve encrypting the same plaintext storied in different locations to different ciphertext; fix the bug that the same plaintext with the same ciphertext; avoid data theft and sabotage from Statistical analysis technique used by data kleptomaniacs and ensure data security.

Keywords: Big data, Finance data, Visualization, Zoom

Abstract. With the advent of the era of big data, data visualization display faces great challenges. Big data, especially in industries such as telecommunications, finance, almost to the point of "data is the business itself". At this time, in order to let more people understand, use and analyze the data better, we proposed the method to display the big data in the field of finance and the notion of the Zoom financial data visualization (ZFDV). By providing a consistent set of the preliminary design of ZFDV and the interaction of ZFDV techniques, ZFDV makes it possible for users to browse through very large data sets. These techniques use the structure of the displayed data to guide the human-interaction and provide a way to improve interactive navigation in the financial.

Introduction

Data has penetrated into every industry and the business functional areas today and data revolution is coming. A fashionable topic with or without Sustainable relevance for research and practice has been researched by Prof. Dr. Hans Ulrich Buhl[1]. Generally speaking, the hope is that if massive data could be exploited effectively, science would extend its reach, and technology would become more adaptive, personalized, and robust. There are also many scientific and engineering fields impacted by massive data which is shown in [2]. But a number of challenges also exist in both data management and data analysis that require new approaches to support the “big data” era.

On the basis of the trait of the financial data, our article proposes the means of zoom. Providing the process of showing data, ZFDV methods will be in consideration of characteristic of the financial data. For example, at first the users could get control of the whole situation after they knew the number of every year. The next layer would set the value in accordance with the users’ expectation.

Our article focuses to demonstrate a method of financial data. When the users check the numbers of the transaction, they can zoom to see all of the data. Using the methods we can accept in our daily lives makes the information easy to understand. The main works we do and discuss are the approaches for both the preliminary design and the interaction of ZFDV. The users can grasp zoom financial data visualization from year to day as Figure1 shows. In this way, we can also know clearly and get the whole view of the finance data which can support for decision making.

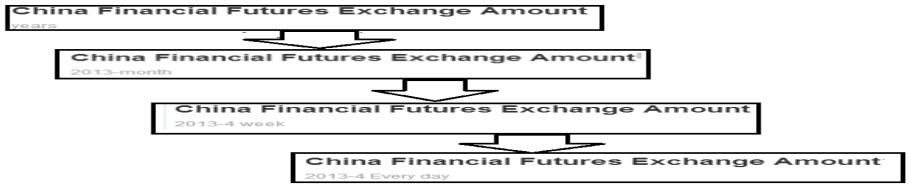

Fig. 1 Zoom financial data visualization from year to day

Related Work

It can be found from the research situation in recent years that much attention has been paid to enhance the visual aspect of graph, text, map and multivariate data, examples include visual analysis of business data[3,4,5]. However, surprisingly, few studies focused attention to the application of financial transactions.

Renaud Blanch and éric Lecolinet[6] proposed the notion of "zoomable treemaps", they put focuses on this point by proposing a set of interaction techniques that aimed at improving the navigation in treemaps. Application is very few in the world of finance, especially Zoom financial data visualization. The most common techniques for navigating in multiscale visual spaces are pan, zoom, and bird's eye views[10].The previous methods especially Renaud Blanch and éric Lecolinet[6]had a good show in data of text in zoom which we have told in this article. However, the problem is that the financial data have its own feature. Therefore they were not suitable for showing in financial data. For the reason of these, we design the program.

Initiatives in research and development that are leading to improved capabilities include developing methods for visualizing massive data[2]. Shixia Liu[7] studied existing technical challenges and propose directions for future research. One of the challenges is the visual scalability which is defined as the capability of visualization tools to effectively display large data sets in terms of either the number or the dimension of individual data elements [8]. Because Keim,D.A[8] told us Scalability is a fundamental challenge for InfoVis, especially with the boom in big data analytics.

Therefore, the program can be regarded as visual component which have the ability to embed in web page. It's really convenience for the users. In sum up, our research is very necessary, we can use data visualization technology and find hidden rules in a large number of financial, communications, and business data so as to provide the basis for decision-making.

The preliminary design of ZFDA

Browsing very large data sets like financial data can be quite inefficient. It can cause confusion when we see the visualization of the charts. The display technologies are used in reality may be not sufficient for browsing data efficiently. A powerful visualization needs to show the data in the number of attributes and the number of relationships effectively. Here we discuss our approaches for both the preliminary design of ZFDV and the human-interaction of ZFDV. So we propose four preliminary modes for ZFDV and next chapter we introduce the interactions of the data.

3.1 same-level financial data

The data of financial futures trading is a big data with every year, every month, every week, every day, or other aspects of trading information. So we choose the data which have the same unit as the same level data. As we all known, the same level data can display together because of the size, the amount, the similar degree of the data. May in certain cases the size, the amount, the similar degree of the data are the same which is conducive to the Comparison of the data.

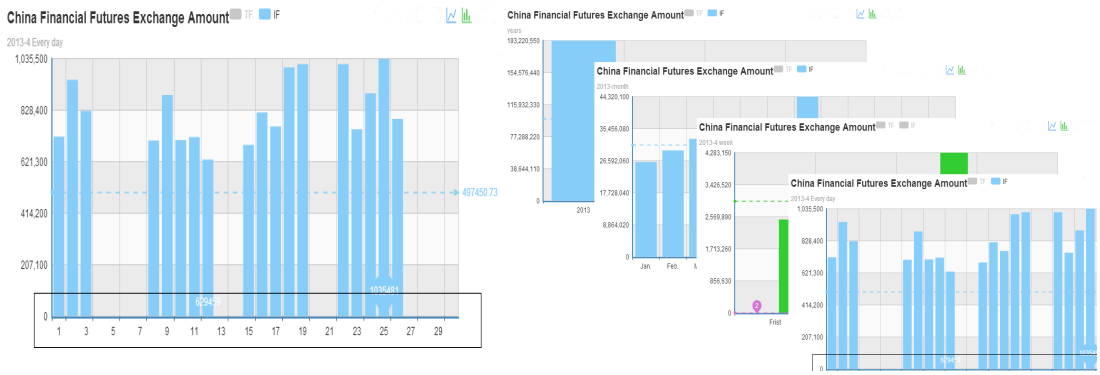

Fig. 2 (Left)Same-level financial data (Right)Different-level financial data

The users may be want to know the details, just as every day in April of 2013, so we unfold the situation of every day. We have taken the needs of users into account while designing our techniques. They make it possible to navigate in same-level financial data as well as in different-level financial data in the financial structure.

3.2different-level financial data

In a certain extent different levels of financial futures trading data can be called the different depth data. Such data can achieve very good zoom function. We can define for depth with N, if N=1, then the data are the next layer. After setting the N, data can display in different depth. Just like treeview, the depth of the different setting will have different display effect. But in this article, the way to define N is year, month, week, day. We know that, the data in finance are Special data because trading is going on in every month of the year, every day of every week. If we don't define N properly, it will cause disorder in visualization. Using the methods we can accept in our daily lives make the information easy to understand.

The right of Figure 2 illustrates this display of different-level financial data: it allows users to switch quickly from one level to one of its next level. The techniques presented so far only make it possible to select the data that are on the same layer as the current picture, or located one level above or below. Since the method we put up to display several layers of the data simultaneously and provide visual access to them, a technique to select any visible layer of the data is most desirable.

3.3 The maximum/minimum data display

Maximum/minimum values can often attract the attention of the audience which tells us this part is really important. Our awareness of the value may be greatly more than other data at the same level, so the picture shows the maximum/minimum values in the design of the program which can help users to check and compare. Moreover maximum/minimum values reflect the upper limit and the lower limit, the whole situation can be easily got caught by the users.

In the left of Figure 3, we can see the maximum/minimum of the data in China Financial Futures Exchange. By comparing in the pictures, the general can be known by the users at a glance.

Fig. 3 (left) The maximum/minimum data display, (right) The average automatically display

3.4 The average automatically display

It is also often desirable to know mean value of the data in the same level, our design can get the mean value automatically. The mean value is very vividly, it aims at helping the user to keep her data orientation. When we analyze the practical problems, the average of the data will be introduced in order to reflect the overall overview of the entire process. Many common types of averages can be seen: geometric mean, arithmetic mean, weighted mean, RMS, etc. Here we use the geometric average. Due to the introduction of the average, the whole situation appears more intuitive and simple, just as the right of Figure 4 demonstrates.

Human-Interactions

A zoom user interface (ZUI) [6] is a useful function to help users deal with large information spaces displayed within a screen[9]. In addition to the visual design, the most important is the visualization of the interaction. At here, we design two interaction modes for ZFDV.

4.1 line or histogram

In order to meet the needs of various users, we design using the histogram and the line chart. Users can view the size and change of the data in different ways. This kind of interaction can satisfy different users and more humanize. We usual use histogram to compare the data of everyday in April of 2013.The problem is that the commonly used method may be not very Suitable for view the change of the data. Therefore line shape plays an important role at this time。

Fig. 4 Line or histogram you can choose

4.2 Layers of in-depth

As mentioned before, our scale form is layers of depth. Figure5 tell us the scenario, when we looked at the original transaction volume throughout the whole year, afterwards if I'm so interested in the data in 2013, I can click to data volume of 2013. Next the data of April catch my attention, so I can click to data volume of 2013 in April. A succession of interests makes me check the numbers of the year, the month, the week, the day. This process is layers of depth of zoom change. Viewing of this scale can meet us for what we are interested in and provide an interesting solution for representing hierarchical data.

Fig. 5 Layers of in-depth

Performance

Through reading the trade data of financial securities transactions in China Financial Futures Exchange[11], our system start to work. According to the sequence of time, the data are stored by layer in advance. For each layer of the data we all gave the same label, if a data with the same label was invoked, then the other data with the same tag also displayed at the same time. Our work used the database or XML which can be written in the way of tree, branch and leaf, to store and call for different levels of financial data. We are only provided for a way of showing transaction data, in the era of big data, we should think more details about how to show the data better.

Conclusion &Future work

As we all known, sometimes one graph may be not show the information very well, so we can use several zoom pictures to display just like we studied in above. These techniques can apply to various applications ranging from network visualization and text visualization。

In this paper, we proposed a new method to display volume of business transactions in financial futures which make it possible to explore massive data in trading financial data. We can check the amount data of every year, every month, every week and even every day which make us feel clearly and easy to understand and compare. The way we propose can reduce the chance for the user to get lost in the information space.

The focus in the future of our work can establish a visual component instead of this special performance. We all know that it must be very popular if the visualization graph is easy to understand and grasp the law, show enough information. Moreover the data sets are multivariate in finance, so an information-aware framework for exploring multivariate data sets[12] and simplification[13] is very necessary. Our future work will be devoted to this aspect.

Keywords: Robust principal component analysis, low rank matrix recovery, iterative threshold algorithm , primal-dual method, background modeling.

Abstract. This paper studies the iterative threshold algorithm (ITA) for solving the Robust Principal Component Analysis (RPCA) problems, which is to recover a low-rank matrix with a fraction of its entries being arbitrarily corrupted. By utilizing the primal-dual method, we analyze the ITA in a new way and prove that the ITA is essentially equivalent to gradient method applying to a dual problem. In the original ITA, it is hard to choose the parameters and hence it converges very slowly. Now, based on the new insight, existing techniques of the gradient method can be used to accelerate the ITA. We combine the theoretical derivation with the numerical simulation experiments to give an empirical guidance to set the parameters. As illustration, background modeling problem is solved by the ITA with optimal parameters.

1. Introduction

Recently, there is a widespread concern about the Robust Principal Component Analysis (RPCA) [1, 2], which is to recover a low-rank matrix with a fraction of its entries being arbitrarily corrupted. It is widely applied in signal processing, image processing, computer vision, machine learning, etc [1]. Suppose that we are given a large date matrix $D \in R^{n_1 \times n_2}$, and know it can be decomposed as $D = A_0 + E_0$, where A_0, E_0 is unknown, but we know the prior information matrix A_0 is of low-rank , E_0 is sparse. The aim of the RPCA is to recover A_0 and E_0 from the given matrix D. Mathematically, we want to solve,

$$\min_{A,E} \|A\|_* + \lambda \|E\|_1, \qquad s.t.\ D = A + E \tag{1}$$

where $\|X\|_*$ equals the summation of the singular values of X, $\|X\|_1$ denotes the summation of the absolute values of a matrix entries. Convex optimization problem (1) is known as the Principal Component Pursuit(PCP) [2]. The weighted value λ between the nuclear norm $\|A\|_*$ and L1 norm $\|E\|_1$ may affect the speed of convergence as well as the final results. Practical experience shows that $\lambda = 1/\sqrt{\max(n_1, n_2)}$ works well for the incoherent matrices [3].

Convex optimization problem (1) has received much attention and many numerical algorithms have been proposed for solving it. For example, the interior point methods, the iterative threshold algorithm (ITA) [4, 5], the accelerated proximal gradient (APG) [6], the augmented Lagrange multipliers (ALM) or exact ALM (EALM) [7], etc. Among these existing algorithms, The ITA is simple and it is the fundament of many methods. However its practical application is greatly limited by the large number of iterations to converge and the difficulty to choose the parameters [6, 7]. In this paper, in section 2, we prove that the ITA is actually equivalent to the gradient method applying a dual problem, which is different from the traditional way. In section 3, we present some implementation details of our algorithm based on our theoretical discovery and do some simulations to study how the different parameters affect the results and the speed of convergence. Then we apply the ITA to the background modeling. We will give some concluding remarks in the final section.

2. Iterative Threshold Algorithm

2.1 The original ITA

Regularize the problem (1), we can obtain the following optimization problem [7],

$$\min_{A,E} \|A\|_* + \lambda\|E\|_1 + \frac{1}{2\tau}\|A\|_F^2 + \frac{1}{2\tau}\|E\|_F^2, \qquad s.t.\ D = A + E \tag{2}$$

where τ is a relatively large positive parameter that can "smooth" the problem (1) [9]. The solution to (2) is also a solution to (1) as long as τ is sufficiently large [10]. However, it has been observed that a larger τ tends to slower convergence. Hence, a moderate τ is needed.

By introducing a Lagrange multiplier Y to remove the equality constraint, we can get the Lagrange function:

$$L(A,E,Y) = \|A\|_* + \lambda\|E\|_1 + \frac{1}{2\tau}\|A\|_F^2 + \frac{1}{2\tau}\|E\|_F^2 + \frac{1}{\tau}\langle Y, D - A - E\rangle \tag{3}$$

Then, the ITA updates A, E and Y iteratively. It updates A or E by minimizing the Lagrange function $L(A,E,Y)$ with the other variables being fixed, respectively. Then updating Y by the equation constraint $D = A + E$ .In detail, the ITA can be described as follows [7]:

$A\lg orithm\,1(Iterative\ \ Threshold\ \ A\text{lgorithm})$

$Input:\ Observation\ matrix\ D \in R^{m\times n}, weights\ \lambda, \tau$

$1: while\ \ not\ converged\ do$ $\qquad 4: E_k = S_{\lambda\tau}[Y_{k-1}],$

$2: (U,S,V) = svd(Y_{k-1}),$ $\qquad 5: Y_k = Y_{k-1} + \delta_k(D - A_k - E_k)$

$3: A_k = US_\tau[S]V^T,$ $\qquad 6: end\ \ while$

$Output\ \ A \leftarrow A_k, E \leftarrow E_k$

where $S_\varepsilon[x]$ is the shrinkage operator defined as: $if\ \ x > \varepsilon, S_\varepsilon[x] = x - \varepsilon$; $if\ \ x < -\varepsilon, S_\varepsilon[x] = x + \varepsilon$; otherwise, $S_\varepsilon[x] = 0$. With shrinkage operator, [4, 11] proved the famous result (4):

$$\arg\min_X \varepsilon\|X\|_* + \frac{1}{2}\|X - W\|_F^2 = US_\varepsilon[S]V^T;\ \ \arg\min_X \varepsilon\|X\|_1 + \frac{1}{2}\|X - W\|_F^2 = S_\varepsilon[W] \tag{4}$$

where USV^T is the SVD of W .

2.2 A primal-dual method to the ITA

In this section, we prove that the ITA can also be obtained by the primal-dual method. Note that $\|X\|_1 = \max\{X^TZ : \|Z\|_\infty \le 1\}, \|X\|_* = \max\{X^TZ : \|Z\| \le 1\}$, the dual problem of (3) is as follows[8,9]:

$$\min_{A,E}\max_Y L(A,E,Y) = \min_{A,E}\max_Y \left(\|A\|_* + \lambda\|E\|_1 + \frac{1}{2\tau}\|A\|_F^2 + \frac{1}{2\tau}\|E\|_F^2 + \frac{1}{\tau}\langle Y, D - A - E\rangle \right)$$

$$= \max_Y\{\frac{1}{\tau}\langle Y, D\rangle\} + \min_A\max_Y\{\|A\|_* + \frac{1}{2\tau}\|A\|_F^2 + \frac{1}{\tau}\langle Y, -A\rangle\} + \min_E\max_Y\{\lambda\|E\|_1 + \frac{1}{2\tau}\|E\|_F^2 + \frac{1}{\tau}\langle Y, -E\rangle\}$$

$$= \max_Y \frac{1}{\tau}\langle Y, D\rangle + \min_A\max_{Y,\|Z_1\|\le 1}\{\langle A, Z_1\rangle - \frac{1}{\tau}\langle A, Y\rangle + \frac{1}{2\tau}\|A\|_F^2\} + \min_E\max_{Y,\|Z_2\|_\infty \le 1}\{\lambda\langle E, Z_2\rangle - \frac{1}{\tau}\langle E, Y\rangle + \frac{1}{2\tau}\|E\|_F^2\}$$

$$= \max_Y \frac{1}{\tau}\langle Y, D\rangle + \max_{Y,\|Z_1\|\le 1}\min_A\{\frac{1}{2\tau}[A - (Y - \tau Z_1)]^2 - \frac{1}{2\tau}\|Y - Z_1\|_F^2\} + \max_{Y,\|Z_2\|_\infty \le 1}\min_E\{\frac{1}{2\tau}[E - (Y - \lambda\tau Z_2)]^2 - \frac{1}{2\tau}\|Y - \lambda\tau Z_2\|_F^2\}$$

$$= \max_Y \frac{1}{\tau}\langle Y, D\rangle + \max_{Y,\|Z_1\|\le 1}\{-\frac{1}{2\tau}\|Y - \tau Z_1\|_F^2\} + \max_{Y,\|Z_2\|_\infty \le 1}\{-\frac{1}{2\tau}\|Y - \lambda\tau Z_2\|_F^2\}$$

$$= -\min_Y\left\{-\frac{1}{\tau}\langle Y, D\rangle + \min_{\|Z_1\|\le 1}\{\frac{1}{2\tau}\|Y - \tau Z_1\|_F^2\} + \min_{\|Z_2\|_\infty \le 1}\{\frac{1}{2\tau}\|Y - \lambda\tau Z_2\|_F^2\}\right\}$$

since $A^* = Y - \tau Z_1,\ \ E^* = Y - \lambda\tau Z_2$.

Eliminating $Z_1,\ \ Z_2$ from the last equation gives the dual problem (5):

$$\min_Y f(Y) \equiv \min_Y\ -\frac{1}{\tau} < Y, D > + \frac{1}{2\tau}\left\|Y - proj_{\{\tau Z_1 : \|Z_1\| \le 1\}}(Y)\right\|_F^2 + \frac{1}{2\tau}\left\|Y - proj_{[-\lambda\tau, \lambda\tau]^n}(Y)\right\|_F^2 \tag{5}$$

with $proj$ is the projection operator defined as $proj_{\mathrm{B}}(v)=\arg\min_{x\in\mathrm{B}}\|x-v\|_2$.

Farther more, according to the property of projection operator [9], we have that

$$W-proj_{[-\mu,\mu]^n}(W)=S_{\mu}[W];W-proj_{\{\tau Z_1:\|Z_1\|\le 1\}}(W)=US_{\varepsilon}[S]V^T \tag{6}$$

where $W=USV^T$ and $S_{\varepsilon}[x]$ is the shrinkage operator defined as section 2.1.Then,

$$A^*=Y-\tau Z_1=Y-proj_{\{\tau Z_1:\|Z_1\|\le 1\}}(Y)=US_{\tau}[S]V^T;E^*=Y-\lambda\tau Z_2=Y-proj_{[-\lambda\tau,\lambda\tau]^n}(Y)=S_{\lambda\tau}[Y] \tag{7}$$

It is easy to say (10) is equivalent to (4). And,

$$\nabla f(Y)=-\frac{1}{\tau}D+\frac{1}{\tau}\left(Y-proj_{\{\tau Z_1:\|Z_1\|\le 1\}}(Y)\right)+\frac{1}{\tau}\left(Y-proj_{[-\lambda\tau,\lambda\tau]^n}(Y)\right)=-\frac{1}{\tau}\left(D-A^*-E^*\right) \tag{8}$$

Applying the gradient iteration to the dual objective $f(Y)$ gives:

$$Y_k=Y_{k-1}+\delta_k(D-A_k-E_k) \tag{9}$$

It is clear that the ITA is essentially equivalent to gradient method applying to a dual problem.

3. Experiments

3.1 Numerical simulations

In the numerical simulations, we test the ITA with different parameters. Firstly, we study how the parameter τ affects the calculated results and the speed of convergence, and make the comparison with the theoretical bound obtained in [10]**.** Then we study the relationship between δ and the number of iterations.

We use randomly generated matrices for simulations, just as in [6, 7]. Firstly we generate the rank- r matrix $A_0=UV^T\in R^{n_1\times n_2}$, where $U\in R^{n_1\times r},V\in R^{n_2\times r}$ are independent matrices whose elements are i.i.d. Gaussian random variables with zero mean and unit variance. Then generate $E_0\in R^{n_1\times n_2}$ as a sparse matrix whose support is chosen uniformly at random, and whose non-zero entries are i.i.d. uniformly in the interval [−500, 500]. We denote the true solution by the ordered pair (A_0,E_0) , $D=A_0+E_0$ is the input, and (A,E) the output. We choose a fixed weighting parameter $\lambda=1/m$ [3] and set $m=n,r=\rho_r*n$, $\|E_0\|_0=\rho_s*n^2$. When the number of iterations reaches to 10000 or $\|D-A-E\|_F/\|D\|_F\le 5e-5$, the Iteration will stop. Meanwhile, we use $rel\ A$ and $rel\ E$ to denote the relative errors of the output solution, i.e., $rel\ A=\|A-A_0\|_F/\|A_0\|_F$, $rel\ E=\|E-E_0\|_F/\|E_0\|_F$.

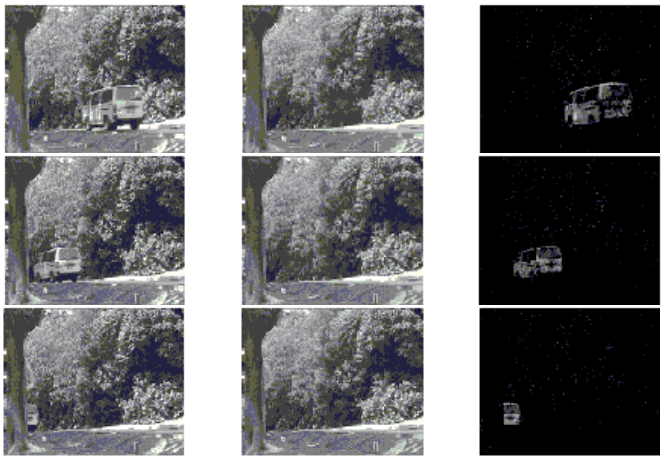
The parameter τ may be quite difficult to set. On one hand, a sufficiently large τ is needed to get the real solution to problem (1); on the other hand, a larger τ tends to converge slowly. The author in [10] derived a theoretical bound of τ . They showed that the bound $\tau\ge 8\sqrt{15}\|D\|_F/3\lambda$ guarantees the decomposition of the observed matrix D into its low-rank component and sparse component.

A brief comparison of how τ affects the calculated results and the speed of convergence is presented in Tables 1. We take $r_0=0.05n$, $\|E_0\|_0=0.05n^2,n=500,\delta=0.9$. It shows that $\tau=10^4$ is better than the other values, while $\tau\le 10^3$, the ITA will not converge any longer. When $\tau\ge 10^6$, the ITA converges so slowly and reaches the maximum number of iterations. However, the bound $\tau\ge 8\sqrt{15}\|D\|_F/3\lambda$ is about $\tau\ge 10^5$. Thus we conclude that the bound $\tau\ge 8\sqrt{15}\|D\|_F/3\lambda$ just give a sufficient conditions but not necessary.

Table 1 Comparison of the ITA on the RPCA problem with different τ . Table 2 Comparison of the ITA on the RPCA problem with different δ . In table 2, $r_0=0.05n$, $E_0=0.05n^2,n=100,\tau=10000$, we can find δ has a great influence on the number of iteration. When δ is too small, it takes too much time for the ITA to converge. And if $\delta\ge 1.6$, it may not converge. We can get the recommendations value of $\delta=1.5$, and it is three times faster than $\delta=0.5$,which was used in [6]. However, our simulations show that when δ is bigger than 1.55, the results begin to deteriorate. To be safe, we can set the experience value around 1.4.

3.2 Background modeling

Background modeling is an popular approach to detecting activity in the scene [2]. The background may contain a lot of information, but it change a little in a short time. The difference between two adjacent pictures may be reflected in the moving things in the pictures.We consider one example video introduced in [12]. It is a sequence of 300 grayscale frames taken in a campus . This video has a relatively static background, but significant foreground variations. The frames have scales of 128×160 ; we stack each frame as a column of the matrix $D\in R^{20480\times300}$. We decompose $D\in R^{20480\times300}$ into a low-rank term A and a sparse term E by solving the convex PCP problem (1) with the ITA. We set $\lambda=1/\sqrt{20480}$, $\tau=(1/100)*8\sqrt{15}\|D\|_F/3\lambda$, $\delta=1.4$. Figure 1(a) shows three frames(204^{th} ,215^{th} and 222^{nd}) from the video of the campus; (b) and (c) show the corresponding columns of the low rank matrix A and sparse matrix E. We can find that A correctly recovers the background, while E correctly recovers the moving car, we can see the direction of the car and even estimate the speed.



(a) (b) (c)

Figure 1 Background modeling taken in the campus[12]. (a) shows three frames; (b) and (c) show the corresponding columns of the low rank matrix A and sparse matrix E .

4. Conclusion

In this paper, we analyze the ITA in a new way and prove that the ITA is essentially equivalent to gradient method applying to a dual problem. And also we combine the theoretical derivation with the numerical simulation experiments to give an empirical guidance to set the parameters. With the optimal parameters, background modeling problem can be solved very well. There are at least two directions that should be investigated in the future. The first direction is the study of accelerating the ITA with restart technique. The second one is to decompose the low rank matrix and sparse matrix from the Gaussian noise.

5. Acknowledgement

We thank the authors of [12] for kindly sharing with us their background modeling dates. The research was supported by NSF 61072118.

Abstract. With the development of science, the scope of application of robot is more and more extensive. The path planning problem of mobile robot ,has been always an important research content of intelligent robot .In this paper , firstly we can construct feasible work space mode , through the random grid method to given the starting point ,end point and each obstacle .Then we can use the improved AFSA for path optimization .In the algorithm ,we ignore the congestion factor ,it is based on the preying behavior ,supplemented by the following behavior and swarm behavior .

Introduction

With the progress of science and the development, mobile robot technology has been further developed. In recent years, the rapid development of science and technology, robots are constantly improving our lives, such as service robots, underwater robots, entertainment robots, military robots, agricultural robots, etc.

Robot path planning is an important criterion of their level of intelligence; it is an essential part in robot navigation techniques. The planning is based on certain rules to find out a non-collision path from the starting point to the target point of optimal or suboptimal. Through sensors, mobile robot can perceive the environment and their own state, to achieve in complex environments autonomous obstacle avoidance, in order to complete a certain job functions of the robot [1].

Mobile Robot Path Planning belongs to a class of NP-Hard problem. To solve this problem, many methods have been proposed. For example grid method, link graph, neural networks, artificial potential field method, ant colony algorithm, the hybrid

This paper studies the robot path planning algorithm based on artificial fish, which is a simulation of the behavior of a variety of fish bionic algorithm. Simulation results demonstrate the effectiveness of the algorithm.

Robot Path Planning Based On AFSA

AFSA [2] [3] is a simulation of the behavior characteristics of fish, and has a new bottom-up optimization model. This algorithm is simulated fish feeding, swarming, and following in the search field to find the best. AFSA has fast convergence, has a good ability to overcome the local minima and to obtain global extremes. There can be used to solve the problem of real-time requirements, and for some low accuracy problem, it can quickly get a feasible solution. This algorithm does not require strict mechanism model of the problem, and even does not require accurate description, which makes it can be used to extend the range of applications. The algorithm has been applied to combinatorial optimization problems [4], the online time-varying system identification [5], the whole set of robust PID parameters [6], before optimization neural networks [7] reactive power optimization [8], and more user detection [9] [10]

Several acts of AFSA:

(1) Feeding behavior: the basic behavior of AFSA, and also tends to food, is a free search behavior. It ensures fast and stable convergence, overcoming local extreme aspects. Let the current state X_i of artificial fish i is randomly selected a state X_j within its sensing range

$$X_j = X_i + Visual * Rand() \quad (1)$$

If $h_j > h_i$ that food concentration is greater than the original state at that point, then further to the front direction

If it is not satisfied, and then determines whether reselection Xj satisfies the condition. After attempting to Try-number times, if it still does not meet the conditions, then immediately move step.

(2)Swarming behavior: In order to ensure the survival of fish population and avoid harm, they will naturally get together. The behavior of the algorithm can effectively enhance the global convergence. Let the current state of artificial fish as X_j, if the partner does more crowded food center, then move one step toward the partner center.

$$X_i^{t+1} = X_i^t + \frac{X_c - X_i^t}{\| X_c - X_i^t \|} * Step * Rand() \quad (2)$$

If it is not met, then perform feeding behavior.

(3)Following behavior: Fish advance to the optimal partner nearby. The behavior enhancement algorithm convergence speed and global. Let the current state of artificial fish is X_j, if there is a partner in the vicinity, which have more food without crowding around, then move one step towards the direction of partners.

$$X_i^{t+1} = X_i^t + \frac{X_j - X_i^t}{\| X_j - X_i^t \|} * Step * Rand() \quad (3)$$

If it is not met, then perform feeding behavior.

Robot Path Planning Design

This article uses the random grid method to create space model. Grid method is a two-dimensional model of the robot motion decomposed into a series of binary information grid. One possibility is to select a paper path. Construction algorithm is as follows:

Let the starting point as g_{begin},, the end as g_{end}. On the grid of the robot along the eight directions, which are allowed in the neighborhood of the robot. In this paper, two cases, the one is feasible to reach the surrounding areas without any conditions; the other do not allow walk along the obstacle corners.

Workspace of the robot is an M * M grid components. In the grid, the obstacles and the feasible region with the binary matrix represent a 0 and 1

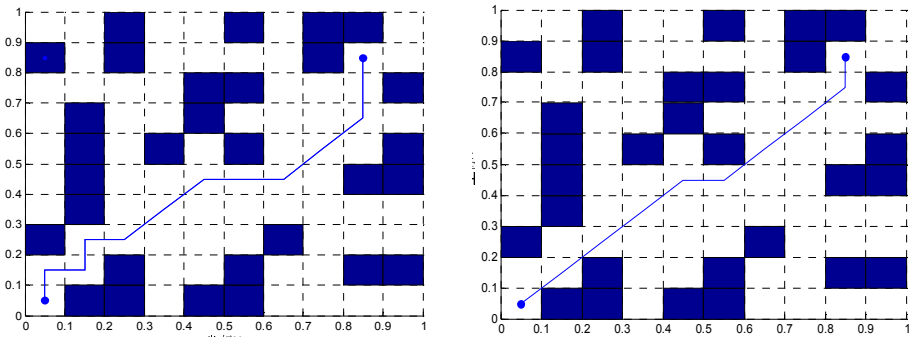
$$B(i,j) = \begin{cases} 1, & \text{obstacle} \\ 0 & no - obstacle \end{cases} \quad (4)$$

Crowding can not get substantive changes, in some cases it will affect the stability of the algorithm and optimization time. So ignore the crowding factor.

Parameter initialization, record global optimum state of artificial fish. Evaluation of artificial fish, acts to be performed on the line be merit, update the location information of each artificial fish. If it meets n>Try number, it ends. The resulting path is the shortest path length; the path is the best path. If it does not meet the conditions, then return to continue.

Test results

In order to verify the robot path planning method based on artificial fish school algorithm correctness and feasibility, the paper simulation. In this algorithm, a total of fish is 10, the maximum number of attempts is 6, and the step is 1 and Square root of 2, the simulation results shown in Figure 1, Figure b is diagonally across from the edge between the obstacle and through the obstacle corners.



(a) Not across from the edge (b) across from the edge

Fig.1. The experimental results

Conclusion

This paper proposes a robot path planning method based on the grid method and improved AFSA, firstly creating barriers to model grid method, then according to AFSA to select the robot walking path, finally the path is obtained optimal path, simulation experiments prove the feasibility of this method

A study of the Keep-Right-Except-To-Pass Traffic Rule on cellular automata

Wenbin Cao[1]

[1] North China Electric Power University, Baoding, China

[a]caowenbin921030@126.com

Keywords: keep-right-except-to-pass rule, three-lane cellular automata, numerical simulation.

Abstract. Traffic rule is set to enable the safety and efficiency of the traffic. This paper takes the keep-right-except-to-pass rule as the research object. A three-lane cellular automaton model is proposed to simulate traffic flow. Through computer simulating, we analyze the relationships among traffic flow, overtaking ratio, average speed and density. The result shows that the rule although can increase the traffic flow and the average speed, the effect is not very evident, while this rule instead can increase driving safety in a large scale.

Introduction

In the USA, China and most other countries, multi-lane freeways often employ a rule that requires drivers to drive in the right-most lane unless they are passing another vehicle, in which case they move one lane to the left, pass, and return to their former travel lane. The rule is called keep-right-except-to-pass rule.

With the increasing demand of traffic flow simulation, the traffic flow model based on cellular automata has been developed. Cellular automata model of traffic flow incorporates a series of vehicle movement rules and traffic rules. On the study of the multi-lane model, Nagatani presented a deterministic cellular automaton model to simulate the traffic flow in a two-lane roadway [1] . Rickert et al. examined a two-lane cellular automaton based on the NaSch model [2].Nagel et al. summarized different approaches to lane changing and classified the multitude of possible lane-changing rules [3]. They used a cellular automaton model for two-lane traffic to generate the density inversion. Liet al. proposed a symmetric two-lane cellular automata model to investigate the aggressive lane-changing behavior of fast vehicle and the effect of different lane-changing probability [4].

In summary, all the previous articles have not studied the relationships among traffic flow, overtaking ratio, average speed and density on freeway traffic flow under different control conditions. This paper will examine their relationships.To study the influence of keep-right-except-to-pass rule on traffic, a three-lane cellular automaton model is proposed. First, overtaking ratio is introduced to measure traffic safety. Next, we put out two different lane-changing rules: rule 1 has no limits on lanes and permit overtaking on any lane; rule 2 is the keep-right-except-to-pass-rule. Through the computer simulate, we analyze the performance of this rule in light and heavy traffic

The establishment of the three-lane cellular automaton model

Assumption. We study the three lanes in one direction of a two-way six-lane freeway in this paper. The first lane is the far left one, the second lane is the middle one, and the third lane is the far right one. In order to construct cellular automaton models, we assume that there is only one type of vehicle and the maximum speed of vehicles on every lane is equal, that is $V_{1,\max} = V_{2,\max} = V_{3,\max} = V_{\max}$.

Definition of variables. Considering the road as three one-dimensional discrete grid point chains in parallel, we define the length of each chain is L , and each grid point will be occupied or empty at each moment. Let $X_i(t)$ be the position of vehicle i at time t, $V_i(t)$ be the speed of vehicle i at time t, the distance between vehicle i and the front vehicle at time t is:

$$gap_i(t) = X_{i-1}(t) - X_i(t) - 1 \tag{1}$$

In order to facilitate the discussions, some important indicators are defined to describe the traffic flow. They are listed as follows.

Overtaking Ratio.When overtaking at a high-speed, the mutual interference among the vehicle flow fields will seriously affect vehicle's aerodynamic characteristics, which will reduce the stability and security of vehicles, and even cause traffic accidents. So the frequency of lane changing is a very important measuring factor for road traffic safety [7]. Based on the above analysis, we take the overtaking ratio P_f, which is the ratio of the total number of overtaking and the number of vehicles observed, as the main indicator of traffic safety level.

Density. We define the density as $\rho(t)=N(t)/3L$, where $N(t)$ indicates the number of all vehicles on the freeway, and L indicates the total length of the road. It is obvious that high density represents heavy traffic and low density stands for light traffic.

*Flow.*The vehicle flow volume Q is the number of vehicles passing affixed point per unit time, $Q=\frac{N_T}{T}$, where N_T is the number of vehicles observed in time duration T.

*Average speed.*The average speed also can be used to denote the degree of the congestion $V_a=\frac{1}{N\times T}\sum_{1}^{T}\sum_{1}^{i}V_i^t$; V_i^t is the speed of vehicle i at time t.

Evolution rules of the vehicle. We divide every evolving process into two steps-move and changing lanes. *Moving Rule.* Vehicles on routes move according to Nagel–Schreckenberg(NS) rules [5] as follows:

(1) Acceleration: $V_i(t+1/3)=\min(V_i(t)+1,V_{\max})$;

(2) Deceleration: $V_i(t+2/3)=\min(V_i(t)+1/3,gap_i)$;

(3) Randomly slowing down with probability: $V_i(t+1)=\max(V_i(t+2/3)-1,0)$;

(4) Location renewal: $X_i(t+1)=X(t)+V_i(t+1)$

where $V_i(t)$ denotes the velocity of the i^{th} vehicle, $V_{\max}$ is the maximum velocity, is defined to be the number of empty sites in front of the i^{th} vehicle at time t and $X_i(t)$ is the position of the i^{th} vehicle at time t.

*Lane changing rules.*In general a driver has motivation to change lanes for better driving conditions. The decision to change must be made based on two essential criteria [6]: (1) The incentive criterion, i.e., there should be a good reason to change lanes, such as keeping a desired high speed or getting rid of jamming; (2) The security criterion, a driver must ensure that the changing action is safe, i.e. she/he will not collide with the cars forward and afterwards in the origin lane and adjacent lanes.

A schematic diagram of a three-lane freeway is presented as follow.

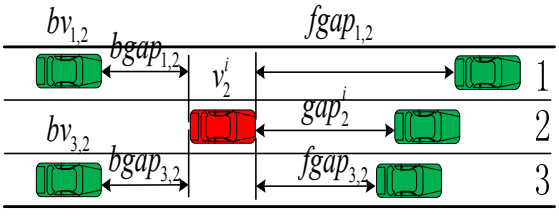

Fig. 1 A three-lane freeway

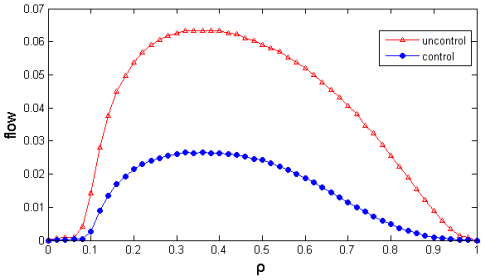

Fig. 2 Relationship between density and overtaking different ratio under control conditions

As shown in Fig. 1, cars on lane 1 and lane 3 can change to lane 2 while cars on lane 2 can change to both lanes 1 and lane 3. We take the car on medium lane 2 as an example to illustrate the meaning of symbols. The distances between car i in lane 2 and its adjacent front car in lane 1, lane 2 and lane 3 are defined as, $fgap_{1,2}$, gap_2^i, $fgap_{3,2}$.The distances between car i in lane 2 and its following car in

lane 1 and lane 3 are defined as $bgap_{1,2}$ and $bgap_{3,2}$.The speed of car i in lane 2 is defined as V_2^i The speed of the following car in lane 1 and lane 3 are $Vb_{1,2}$ and $Vb_{3,2}$. Let γ be the lane changing probability that taking into account the actual situation that some drivers like driving in a certain lane, and will not take the initiative to change.

Thus we adopt symmetric lane-changing rules set, which can be described as Eqs. (2)-(6) as follows[8]: the speed of the vehicle after lane changing will remain unchanged.

Rule 1

Change from lane 1 to lane 2 if

$$fgap_{2,1} \geq \min(V_i + 1, V_{\max}), bgap_{2,1} \geq bV_{2,1}, random > \gamma_{1,2} \quad (2)$$

Change from lane 2 to lane 1 if

$$gap_2^i(t) \leq \min(V_2^i(t) + 1, V_{\max}), fgap_{1,2} \geq gap_2^i, bgap_{1,2} \geq bV_{1,2}, random > \gamma_{2,1} \quad (3)$$

Change from lane 2 to lane 3 if

$$gap_2^i \geq fgap_{1,2}, \ gap_{3,2} \geq gap_2^i, bgap_{3,2} \geq bV_{3,2}, random > \gamma_{2,3} \quad (4)$$

Change from lane 3 to lane 2 if

$$gap_3^i(t) \leq \min(V_3^i(t) + 1, V_{\max}), fgap_{2,3} \geq gap_3^i, bgap_{2,3} \geq bV_{2,3}, random > \gamma_{3,2} \quad (5)$$

Rule 2 (The Keep-Right-Except-To-Pass Rule that is the cars on the passing lane are controlled)

We only need to modify part of the Rule 1, and then we can get Rule 2(The Keep-Right-Except-To-Pass Rule), which is mentioned in question given. When the driver driving on the passing road meets the condition of lane changing, he/she must change lane. Specific rules are presented as follow.

Change from lane 1 to lane 2 if

$$gap_1^i(t) \geq \min(V_1^i(t) + 1, V_{\max}), bgap_{2,1} \geq bV_{2,1} \quad (6)$$

The rest part is the same as Rule 1.

Numerical simulation results and discussion

Suppose every grid point represents 7.5m on lanes, and each time step Δ t≈1s, every time vehicles can at most move 5 grid points, that is $V_{\max} = 5$, then the corresponding speed would be 135km/h. In the simulation, assume L=2000 grid points, that is 15km, which is equivalent to a highway section without ramp. We also adopt periodic boundary conditions and assume the original car densities of the three lanes are equal. After 40,000 evolution steps, and averaging the last 1000 steps based on time, we have obtained the following experimental results. In order to eliminate the effect of randomicity, we take the systemic average of 20 samples. The lane-changing probability is set to be 0.5 unless otherwise specified. The simulation results are presented as follows.

Impact of different rules on overtaking ratio. It can be seen from Fig.2: (1) When the vehicle density is less than 0.38, the overtaking ratio will continue to rise with the increase of vehicle density; when the vehicle density is larger than 0.38, the overtaking ratio will decrease; when density is greater than 0.9, due to the crowding, it will become difficult to overtake, so the overtaking ratio is almost 0; (2) The overtaking ratio in the condition of uncontrolled passing lanes is higher than that in controlled lanes, no matter the traffic is light or heavy. Since the overtaking ratio is an important indicator to measure safety, it would be more unsafe if the rate is higher, in other words, after controlling the passing lanes, the safety of driving will increase in a large scale. Under the Keep-Right-Except-To-Pass Rule, the first lane is defined as passing lane, and if vehicles meet the condition to change to the second lane, they could not stay in the passing lane. This rule doesn't alter the characteristics of traffic flow; instead, it intensifies the safety of driving, while the three-lane uncontrolled traffic mode permits drivers to overtake others in any lane once they meet the condition. Therefore, this rule could effectively increase the safety of driving and reduce the rate of accidents.

Impact of different rules on traffic flow. It can be seen from Fig.3: (1) When vehicle density is lower than the critical density (approximately 0.15 in Fig3.), the traffic flow under two control rules will both rise with the increase of the vehicle density. In contrast, when vehicle density is greater than 0.15, the traffic flow will decrease with the increase of the vehicle density. (2) When vehicle density is lower than 0.15, the traffic flow of the two control conditions are basically the same. Except that, the traffic flow under uncontrolled condition (rule 1) is slightly larger than controlled condition (rule2). Although the Keep-Right-Except-To-Pass rule can improve the flow, the results are not that effective.

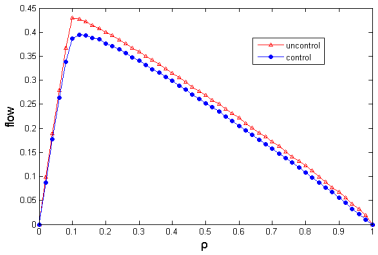

Fig 3. Relationship between density and traffic flow under different control conditions

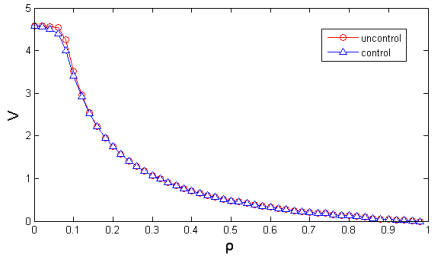

Fig 4. Relationship between density and speed under different control conditions

Impact of different rules on velocity. It can be seen from the Fig4. : The average speed will both reduce with the increase of vehicle density on two conditions. Besides, when vehicle density is greater than 0.15, the average speed under two conditions are almost the same. In other words, this rule cannot increase the average speed just as the flow.

Conclusions

In this paper, we have established three-lane cellular automata models, studied the overtaking ratio, speed and traffic flow under different control conditions, vehicle density,etc. and come to the following conclusions: (1)The keep-right-except-to-pass-rule although can increase the traffic flow and the average speed, the effect is not very evident, while this rule instead can increase driving safety in a large scale. (2)In fact, computer simulation has its limitations and the lane changing process is very complex. So in the future, we will combine measured data to examine the quantitative relationship between vehicle density and mixing ratio and factors such as lane changing and overtaking frequency.

Keywords: Markov chain; transitive closure; model checking; shortest path ; minimal connected components

Abstract. In probabilistic model checking, use discrete time Markov chain (DTMCs) to represent the model and use a branch of the temporal logic called probabilistic computation tree(PCTL) to represent the properties of the model. In this paper, we presents several counterexample generation algorithms for DTMCs violating a PCTL formula, presented as follows: first, according to the transitive closure to reduce the model size against the specific properties of the model, second, using the minimal connected components to generate the equivalent acyclic graph, third, we use the algorithm of the operational research to obtain a shortest path between two points. Experimental results show that our algorithm greatly simplifies the model size and generate more reasonable counterexamples with least states and paths.

Introduction

Model checking, which have developed in the last two decades to the point where major design companies are beginning to integrate them in their normal quality assurance process, is a very successful technique to automatically analyze the correctness of a finite state system. The term model checking was proposed by Clarke and Emerson in the early eighties and the capacity of model checkers to systems was restricted with a few million states .

This paper considers properties in probabilistic model checking, which is a technique to verify system models in which transitions are equipped with random information. Discrete time Markov chains (DTMCs) are a well-known modeling formalism for probabilistic systems. To describe properties of DTMCs we consider the unbounded fragment of probabilistic computation tree logic (PCTL).A major strength of model checking is the possibility to generate counterexamples in case a property is violated. As a result, advanced counterexample generation and analysis techniques have intensively been investigated [1-5].

Most related to our work is the latter approach[4].The paper is organized as follows: In section 2 we introduce some standard definitions notations and theoretical foundations. We provide describes our model reduction algorithm in Section 3 and introduce our model abstraction based on MCC in Section 4.Section 5 describes our counterexample generation method. The experiments are showed in Section 6. We conclude our work and discuss future work in Section 7.

Preliminaries

In this section we introduce discrete-time Markov chains and probabilistic computation tree logic, and define counterexamples in this probabilistic setting. Discrete-time Markov chains are a frequently used modeling formalism for stochastic systems with a discrete state space and a discrete model of time. We first introduced it as follow.

Definition 1 (DTMC) A discrete-time Markov chain (DTMC) is a tuple $M = (S, S_I, P, L)$ with a non-empty finite state set S, $S_I \subset S$ the set of initial states, $P: S \times S \rightarrow [0,1]$ a matrix of transition probabilities with $\sum_{s' \in S} P(s, s') = 1$ for all $s \in S$, and a labeling function $L: S \rightarrow 2^{AP}$ such that AP a set of atomic propositions.

Obviously, a DTMC is like a Kripke structure but transitions are equipped with discrete probabilities such that the sum of outgoing transitions of each state equals 1. It can transform a DTMC with multiple initial states to a DTMC with a single initial state, without changing the probability of the verified property. In this paper we just consider the single initial state. So we redefine a MDTC is a tuple $M = (S, s_I, P, L)$ with a single initial state.

Definition 2 (Paths) An finite path π in $M = (S, s_I, P, L)$is an finite sequence of stats, e.g. $s_0 s_1 s_2 \cdots s_k$such that $\forall\, 0 \le i \le k-1$, $s_i \in S, P(s_i, s_{i+1}) > 0$. An infinite path π is an infinite sequence of stats, e.g. $s_0 s_1 s_2 \cdots s_k \cdots$ such that $\forall\, 0 \le i$， $s_i \in S, P(s_i, s_{i+1}) > 0$.

We write $Path_{fin}^{M}$ for the set of all infinite paths of M, $Path_{inf}^{M}(s)$ for those starting in $s \in S$. As well $Path_{inf}^{M}$ is the set of all finite paths of M, $Path_{inf}^{M}(s)$ of those starting in $s \in S$ $Path_{inf}^{M}(s, t)$ denote the set of finite paths starting in $s \in S$ and ending in $t \in S$.

A finite path π can represent a set of infinite paths which have the same prefix π. We introduce a new notion, which is called an cylinder set ,$Cyl(\pi)=\{\pi^{inf} \in Path_{inf}^{M} |\ \pi \text{ is a prefix of } \pi^{inf}\}$.

At last we introduce for each state $s \in S$ a probability space $(\Omega_s^M,\ F_s^M,\ Pr_s^M)$ on the infinite paths of a DTMC starting in s. The sample space Ω_s^M is the set $Path_{inf}^{M}(s)$. The F_s^M, power set of the sample space Ω_s^M, was defined as :the cylinder set of a finite path π of M. Pr_s^M is the probability measure Pr_s^M: $F_s^M \to [0,1]$ such that the probabilities of the cylinder sets are given by

$$Pr_s^M\left(Cyl(s_0 s_1 \cdots s_n) = \prod_{i=0}^{n-1} P(s_i, s_{i+1})\right)$$

For a set $R \subseteq Path_{inf}^{M}(s)$ we define $Pr_s^M(R) = \sum_{\pi \in R'} Cyl(\pi)$ with $R' = \{\, \pi \in R \mid \forall \pi' \in R, \pi \text{ does not have a prefix } \pi' \,\}$.

Definition 3 (PCTL) Probabilistic computation tree logic (PCTL) is an extension of CTL in which state formulas are interpreted over states of DTMC and path formulas interpreted over infinite paths in a DTMC. The syntax of PCTL is $\Phi ::= true|p|\neg\Phi|(\Phi \wedge \Phi)|P_{\lhd\lambda}(\Phi \mathcal{U} \Phi)$ with $p \in AP$, $\lambda \in [0,1]$ a probability threshold, and $\lhd \in \{<,\ >,\ \le,\ \ge\}$ a comparison operator. For a PCTL state formula φ we define the "future" operator F as $P_{\lhd\lambda}(F\varphi) = P_{\lhd\lambda}(true \mathcal{U} \varphi)$.

In case a property $P_{\le\lambda}(\varphi_1 \mathcal{U} \varphi_2)$ is violated for a DTMC M, a counterexample is a set $C \subseteq Path_{inf}^{M}(s)$ starting in initial state s such that all infinite paths from their associated cylinder sets satisfy $\varphi_1 \mathcal{U} \varphi_2$ and $Pr_s^M(C) > \lambda$. A method in [2] can be used to reduce properties with lower bounds to the former case.

The method in[2], we usually use to check a property $P_{\lhd\lambda}(\varphi_1 \mathcal{U} \varphi_2)$, is to (1) generate a labeling for the sub-formulae φ_1 and φ_2 possibly by recursively invoking probabilistic model checking for sub-formulae,(2) reduce the DTMC with all states satisfying $\neg\varphi_1 \wedge \neg\varphi_2$ get absorbing , and (3) obtain the probability φ_2 states called target states from initial state to the φ_2 states in the reduced DTMC. In this paper, we remove the states and the transitions without relation of reaching the target states from the initial state after the second step. For the last point, just as dealing with the multiple initial states ,we just consider the single target state by transforming a DTMC with multiple target states.

In summary, we just consider the property$P_{\le\lambda}(Fp)$ on the DTMC with a single initial and target state representing the property, on account of we can compute others by some equivalent transformation.

Reduction Model

Prior to checking the validity of a PCTL formula for the DTMC, we modify the DTMC by transitive closure of a single initial and target state. The transitive closure is introduce as follow:

Definition 4 (Transitive closure) $Tc_s^M \subseteq S$ is a transitive closure for $s \in S$ of the DTMC $M = (S, s_I, P, L)$iff $\forall t \in Tc_s^M$, $Path_{inf}^{M}(s, t) \neq \emptyset$.

A transitive closure for a state is the collection of all states it can be reached. The transitive closure can be obtain by algorithm 1. In relation to the transitive closure, we define reverse

transitive closure for $t \in S$ of the DTMC $M = (S, s_I, P, L)$. $RTc_s^M \subseteq S$ is a reverse transitive closure iff $\forall s \in Tc_s^M, Path_{inf}^M(s,t) \neq \emptyset$. We can get the a reverse transitive closure with algorithm 1 by replacing FindPreviousr as FindSuccessor.

Algorithm 1. Transitive closure and reverse transitive closure.

Input：state s
Output：stateSet closure
closure=now=new={s}
while new!= ∅ do
    new=∅
    for state in now
        next=FindPreviousr(state)
        new=new∪ $\{t \in next | t \notin closure\}$
    end for
    now=new
    closure=new∪closure
end while

Applying the above initial transitive closure $Tc_s^M$and target reverse transitive closureRTc_t^M for a DTMC M yield the $Sc_t^s = Tc_s^M \cap RTc_t^M$. According to the Sc_t^s,we modify the DTMC $M = (S, s_I, P, L)$with a single initial state s and a single target state t and turn it into a new DTMC, written $M' = Reduce(M, Sc_t^s)$, $M' = (S', s_I', P', L')$).We describe the DTMC M' has state space $S' = Sc_t^s \cup s_{error}$ for $s_{error} \notin Sc_t^s$, $L(s') = L(s')$ for $s' \in Sc_t^s$, and $L'(s_{error}) = \emptyset$, P' as follows:

$$P'(s_1, s_2) = \begin{cases} 1 & s_1 = s_2 = s_{error} \\ P(s_1, s_2) & s_1 \in Sc_t^s \wedge s_2 \in Sc_t^s \\ \sum_{s' \notin Sc_t^s \wedge s' \in S} P(s_1, s') & s_1 \notin Sc_t^s \wedge s_2 = s_{error} \\ 0 & \text{o. w.} \end{cases}$$

It is obvious that a finite path $\pi \in Path_{fin}^M(s,t)$ of a DTMC M can be described by a finite path of a reduce DTMC $M' = (S', s_I', P', L')$.

MCC-based Model Abstraction

In this section ,we introduce our algorithm to a DTMC M based on the MCC. We define a new set of states ,called a minimal connected component(MCC), and abstract the set of all path fragment through the (MCC) just as in[1].

Definition 5 (MCC) In a $M = (S, s_I, P, L)$,we say $s \in S$ can reach $t \in S$ iff $\exists \pi = ss_0s_1 \cdots s_kt \in Path_{fin}^M(s,t), 0 \leq i \leq k, s^i \in S$. And if t can also reach s, then s and t are connection. A state set $S' \subseteq S$ is called connection in M iff $\forall s \in S', t \in S'$, s,t are connection. We denote S' is a minimal connected component (MCC) of M iff S' is connection in M but $\forall S'' \subseteq S'$, S'' is not connection in M.

We will introduce some more concepts before we talk about the algorithm. For a set $S' \subseteq S$ of $M = (S, s_I, P, L)$, the set $Inp^M(S')$=$\{t \in S' | t = s_I \vee \exists s \in S - S', P(s,t) > 0\}$ is the input state of S'. Analogously, $Out^M(S')$=$\{t \in S - S' | \exists s \in S'\ P(s,t) > 0\}$ means all the stats outside the S'.

The last thing we need to introduce is to get a abstracted DTMC without loop, written $M_{abs} = (S_{abs}, S_{Iabsc}, P_{abs}, L_{abs})$. The smaller M_{abs} specify the probability for the transitions from each input state s to each output state t. This probability mass is determined in two steps: First, we compute for each input state s and output state t the total probability mass p_{st} of all finite paths from s to t without loop. We obtain the probability of the transition by $P(s,t)$=$p_{st}/\sum_{t' \in Out^M(S')} p_{st'}$. The strict and detail correctness is proved in[1].

Definition 6 (Abstraction of M) Let $M = (S, s_I, P, L)$ be a DTMC and a MCC $S' \subseteq S$ is not absorbing. We define the abstraction of $M_{mcc} = (S_{mcc}, S_{Imcc}, P_{mcc}, L_{mcc})$,written $M_{abs} =$

$(S_{abs}, S_{Iabsc}, P_{abs}, L_{abs})$,with $S_{abs} = Inp^{M}(S') \cup (S - S')$, $S_{Iabs} = s_I$ and $L_{abs}(s) = L(s)$ with $s \in S_{abs}$, $P_{abs(s_1,s_2)}$described as follow:

$$P_{abs(s_1,s_2)} = \begin{cases} p_{st} \Big/ \sum_{t' \in Out^{M}(S')} p_{st'} & s_1 \in Inp^{M}(S') \wedge s_2 \in Out^{M}(S') \\ P(s_1, s_2) & \text{o.w.} \end{cases}$$

It is not affect the total probabilities of reaching a target state from an initial state in M_{abs}. The abstraction is described by M_{abs}=Abstract(M,MCC). We introduce algorithm 2 to abstract the M.

Algorithm 2. Abstraction of Model

```
Input：DTMC  M
Output：DTMC  M, TwoTupleDTMC  Rep
s:= initial state of M
MCCs:=getMCCs (s,M)
while MCCs !=∅ do
    for MCC in MCCs
        M_abs=Abstract(M,MCC)
        Rep=Rep∪ (M_abs, M_mcc)
        M=M_abs
        MCCs:=getMCCs (s,M)
    end for
end while
```

we can use algorithm 2 to get new DTMC without loops, which is easier to check model much. In algorithm 2 ,we need to detect the MCCs by getMCCs using the algorithm 3.

Algorithm 3. Detecting MCCs

```
Input：state s，DTMC M
OutPut：MCCSet  MCCs
Low[s]=DFN[s] =++Index
Stack.push(s)
for (s,u) in P(s,u)>0  DescendOrderBy DFN[u]
    if s!=u
        if  u is not visite
            getMCCs (s，M)
            Low[s]=min(Low[u],Low[s])
        else
            if s and u in Stack
                Low[s]=min(Low[s],DFN[u])
                Repeat
                    P=Stack.Pop
                    MCC=MCC ∪ P
                Until p==u
                MCCs=MCC ∪ MCCs
                MCC=∅;
            end if
        end if
    else p=Stack.pop;
end for
```

Counterexample Generation

In this section we introduce our framework for the generation of probabilistic PCTL counterexamples based on MCCs abstraction and model reduction. Our computation is based on the detection of single paths. Instead of just collecting found paths, we use a new DTMC, which is

called critical subsystems and is builded by all transitions appearing in the found counterexample paths, to represent counterexample. Intuitively, a critical subsystem is a part of the original system in which the given probability bound is already exceeded, no matter what happens outside the subsystem.

In our algorithm 4, an DTMC based on the MCC abstraction is the input argument. As the most significant ingredient, we introduce the new approach to compute the shortest path reaching the target state from the initial state in a DTMC M without loops. The method ModelCheck is introduced in[5]. In order to finding paths, we introduce algorithm 5 to implement the path search procedure FindNextPath as invoked by algorithm 4.

Algorithm 4. Incremental generation of critical subsystems

Input：DTMC M, TwoTupleDTMC Rep, doble λ

Output：DTMC CriticalSystem

```
Trans=NewTrans=CriticalSystem=∅
if ModelCheck(M) >λ
    while ModelCheck(M)≤ λdo
        s:= initial state of M，t:= target state of M，NewTrans=∅
        M=ChangeModel (Critical，M)
        NewTrans=GetShortestPath(s，t)
        if  NewTrans≠ ∅
            Trans=Trans∪ NewTrans
            CriticalSystem := GetNewCritical(Trans)
        end if
     end while
     CriticalSystem=Concretize(Trans,Rep)
end if
```

In the algorithm 4, we use the method ChangeModel to change the DTMC M. So that the most probable path in the new DTMC corresponds to the second-most probable path of the original DTMC. The idea is detailed in[5]. Instead of using a set theoretic variant of Dijkstra's algorithm, we use new algorithm 5 based on a set of recursive equations to compute the probable path of a DTMC. This method is called by algorithm 4 as GetShortestPath.

Algorithm 5. Shortest Path of Two Certain States

Input：state s，state t

Output：TwoTuple (p, π)

```
if s=t
    (p, π) = (1， s)
else
    for (u,t) in   P(u,t)>0
        (p, π): =  recursive calls (s,u)
    end for
end if
```

We adopt the algorithm 5 to search a shortest path, which fits well to our problem without the cycles. It can be solved in time O(nm) with that n is the number of the states |S|, and m is the number of nonzero elements in P. This is indeed in polynomial time.

Experimental results

To test our algorithms, we developed a prototype implementation in C++.We used this tool run some experiments on a 3.06 GHz Pentium(R) Dual-Core CPU with 4 GB RAM. We used Prism[7]to generate models for different instances of the parametrized crowds protocol.

The crowds protocol is used to protect users' anonymity on web browsing. In our model we verify the property $P_{\leq\lambda}(F_{\text{pos}})$, where the pos means the positively identified bad user. We generate the counterexample of the M with the different parameters R and Goods.

First of all, we demonstrate our reduction algorithm in the three section. Table 1 contains information about the original model and the reduction model for the crowds protocol. The models are therefore parametrized by R and Goods. OStates and OTransitions represents number of the states and transitions of the original model, while NStates and NTransitions are described the reduction model. Table 2 depicts results for the crowds protocol comparison to the classic algorithm in[2]. We can find that our algorithm get the less paths and states with reduction the infinite loop paths to several paths.

Table 1 Reduction Model Results for the Crowds Protocol

Goods	R	OStates	OTransitions	NStates	NTransitions
5	4	3515	6035	2116	3651
10	3	6563	15143	2556	6637
5	6	18817	32677	7254	12589

Table 2 Counterexample Results for the Crowds Protocol

Goods	R	λ	classic			MCC		
			Paths	States	Total Prob	Paths	States	Total Prob
5	4	0.11	14879	1219	0.1103	379	632	0.110003
5	4	0.13	30033	1249	0.131981	610	914	0.130001
5	6	0.01	28484	1082	0.0100005	435	456	0.0100056
5	6	0.015	183844	2296	0.0150515	1352	550	0.0150085

Conclusion and Future Work

In the paper we introduced new approaches with reduction and abstraction the model to generate counterexamples for DTMCs and PCTL properties. We prove both correctness and efficiency of our algorithm. In future we are going to optimize our approaches with distributed computing technology. Another direction of research is the new framework for the symbolic in[5].

Computing Volumes Surrounded by a Quadric Surface and a Plane with MATLAB

Qingli Yin

Department of Laboratory and Facility Management, Shandong Jianzhu University, Jinan 250101, China

E-mail address: yinql69@163.com

Keywords: quadric surface, plane, volume

Abstract. We describe how to compute volumes of solids surrounded by a quadric surface and a plane. First, we use coordinate transformations to change an equation of a quadric surface into a standard equation, then apply integration techniques to find formulae of computing volumes. A MATLAB procedure is programmed that can be used to evaluate volumes bounded by a quadric surface and a plane.

Introduction

The topic of how computing volumes of solids between a quadric surface and a plane have been studied by Wei-Chi Yang, V. V. Shelomovskii and S. Xia, several useful formulae of finding volumes were obtained in [1, 2, 3]. Solids bounded by a quadric surface and a plane may have a finite or infinite volume. Only the solids with finite volumes are studied here. According to the classification of quadric surfaces (see [4]), there are only an ellipsoid, a hyperboloid of two sheets, a cone and an elliptic paraboloid possibly bounding a finite volume with a plane. For a given quadric surface, we firstly identify it whether an ellipsoid, a hyperboloid of two sheets, a cone and an elliptic paraboloid, then change its equation into a standard equation. For standard equations of quadric surfaces, integration techniques are applied to them to find formulae of computing volumes. In this paper, a MATLAB procedure based on the formulae is programmed and its performance is demonstrated with illustrative examples. Before using the function, please draw a figure of a quadric surface and a plane to confirm the solid bounded by them with finite volume. The procedure is programmed with formal parameters, users need only input the equations of a quadric surface and a plane, the function will output the volume we desire.

A Standard Equation of A Quadric Surface

For a given real quadric surface S with form:

$$f(x,y,z)=a_{11}x^2+a_{22}y^2+a_{33}z^2+2a_{12}xy+2a_{13}xz+2a_{23}yz \\ +2a_{14}x+2a_{24}y+2a_{34}z+a_{44}=0. \tag{1}$$

Set

$$I_1=a_{11}+a_{22}+a_{33},\quad I_2=\begin{vmatrix}a_{11}&a_{12}\\a_{12}&a_{22}\end{vmatrix}+\begin{vmatrix}a_{11}&a_{13}\\a_{13}&a_{33}\end{vmatrix}+\begin{vmatrix}a_{22}&a_{23}\\a_{23}&a_{33}\end{vmatrix},\quad I_3=\begin{vmatrix}a_{11}&a_{12}&a_{13}\\a_{12}&a_{22}&a_{23}\\a_{13}&a_{23}&a_{33}\end{vmatrix},\quad I_4=\begin{vmatrix}a_{11}&a_{12}&a_{13}&a_{14}\\a_{12}&a_{22}&a_{23}&a_{24}\\a_{13}&a_{23}&a_{33}&a_{34}\\a_{14}&a_{24}&a_{34}&a_{44}\end{vmatrix}.$$

We know that I_1, I_2, I_3 and I_4 are invariants of $f(x,y,z)=0$ under an orthogonal transformation, and they can be used to determine the type of S (see [4]). The surface S is an ellipsoid if $I_2>0,\ I_1I_3>0,$ and $I_4<0$; S is a hyperboloid of two sheets if $I_3\neq 0,\ I_2\le 0$ and $I_4<0$; S is a cone if $I_3\neq 0,\ I_2\le 0$ and $I_4=0$; S is an elliptic paraboloid if $I_3=0,\ I_4<0$.

Recall that an ellipsoid, a hyperboloid of two sheets and a cone are surfaces with a central point and they have three orthogonal principal diametral planes. Suppose the coordinates of central point of S are (x_0,y_0,z_0), then they satisfy:

$$\begin{cases} a_{11}x_0 + a_{12}y_0 + a_{13}z_0 + a_{14} = 0 \\ a_{12}x_0 + a_{22}y_0 + a_{23}z_0 + a_{24} = 0 \\ a_{13}x_0 + a_{23}y_0 + a_{33}z_0 + a_{34} = 0 \end{cases} \quad (2)$$

The characteristic equation of S is

$$-\lambda^3 + I_1\lambda^2 - I_2\lambda + I_3 = 0. \quad (3)$$

We replace the characteristic roots $\lambda_1, \lambda_2, \lambda_3$ into the system of equations separately,

$$\begin{cases} (a_{11} - \lambda_i)X + a_{12}Y + a_{13}Z = 0 \\ a_{12}X + (a_{22} - \lambda_i)Y + a_{23}Z = 0 \\ a_{13}X + a_{23}Y + (a_{33} - \lambda_i)Z = 0 \end{cases}, \quad (4)$$

solving the equations we get the principal directions $X_i : Y_i : Z_i \ (i = 1,2,3)$ of S. Substituting $X_i, Y_i, Z_i (i = 1,2,3)$ into the equation $X_i(a_{11}x + a_{12}y + a_{13}z + a_{14}) + Y_i(a_{12}x + a_{22}y + a_{23}z + a_{24}) + Z_i(a_{13}x + a_{23}y + a_{33}z + a_{34}) = 0$, the principal diametral planes of S are obtained. If we take the three principal diametral planes as new coordinate planes, and make an orthogonal transformation, then S is transformed into S' with form $\lambda_1 x'^2 + \lambda_2 y'^2 + \lambda_3 z'^2 + \frac{I_4}{I_3} = 0$ and the plane P is changed into a plane P_1.

For an elliptic paraboloid, since it has a characteristic root $\lambda = 0$, it has only two principal diametral planes, we pick a plane as third new coordinate plane that is vertical to the two principal diametral planes, then S is changed into S' with form $\lambda_1 x'^2 + \lambda_2 y'^2 + 2a'_{34}z' + a'_{44} = 0$ and the plane P is changed into a plane P_1.

Methods of Computing Volumes

Suppose that a quadric surface has a standard equation, we calculate volumes of solids surrounded by a quadric surface and a plane using traditional method.

A. Volume of a solid surrounded by an ellipsoid and a plane

Supposed an ellipsoid equation S with form $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$ and a plane P with equation $a_1x + b_1y + c_1z = d_1$. Making a linear transformation: $x = ax'$, $y = by'$, $z = cz'$, S is converted into an unit sphere S', and the plane P is changed into P': $a_2x' + b_2y' + c_2z' = d_2$. The Jacobian determinant of the linear transformation is denoted by J. Recall that the volume of a spherical segment is $\pi h^2(R - h/3)$, where R is the radius of the sphere and h is the height of the segment. If let d be the distance from the origin to the plane P', then $h = R - d$ (or $h = R + d$). Finally, the volumes of pieces surrounded by S and P are obtained by the formula $\pi h^2(R - h/3)|J|$.

B. Volume of a solid surrounded by a hyperboloid of two sheets and a plane

Suppose a hyperboloid of two sheets S with form $\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = -1$ and a plane P with equation $a_1x + b_1y + c_1z = d_1$. The intersections of the given quadric and parallel planes is a set of similar ellipses. The volume of the solid surrounded by S and P is calculated by the formula: $V = \frac{\pi abc}{3}(2 + 3\mu - \mu^3)$, $\mu = -\frac{|n_0|}{w}$. Where, $w = \sqrt{-n_1^2a^2 - n_2^2b^2 + n_3^2c^2}$, $n_1 = \frac{a_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}}$, $n_2 = \frac{b_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}}$, $n_3 = \frac{c_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}}$, $n_0 = \frac{-d_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}}$. This formula was obtained by V. V. Shelomovskii and Wei-Chi Yang in [3]. If S with form $-\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = -1$ or $\frac{x^2}{a^2} - \frac{y^2}{b^2} + \frac{z^2}{c^2} = -1$, we have a similar formula.

C. Volume of a solid surrounded by a cone and a plane

Suppose a cone S with form $\frac{x^2}{a^2}-\frac{y^2}{b^2}-\frac{z^2}{c^2}=0$ and a plane P with equation $a_1x+b_1y+c_1z=d_1$. By the technique used in the paper [3], we get the volume formula that calculates the volume of the solid surrounded by a cone S and a plane P: $V=\frac{\pi abc|n_0|^3}{3w^3}$, where $w=\sqrt{n_1^2a^2-n_2^2b^2-n_3^2c^2}$, $n_1=\frac{a_1}{\sqrt{a_1^2+b_1^2+c_1^2}}$, $n_2=\frac{b_1}{\sqrt{a_1^2+b_1^2+c_1^2}}$, $n_3=\frac{c_1}{\sqrt{a_1^2+b_1^2+c_1^2}}$, $n_0=\frac{-d_1}{\sqrt{a_1^2+b_1^2+c_1^2}}$.

D. Volume of a solid surrounded by an elliptic paraboloid and a plane

Suppose an elliptic paraboloid S with form $\frac{x^2}{a^2}+\frac{y^2}{b^2}=z$ and a plane P with equation $a_1x+b_1y+c_1z=d_1$. The volume of the solid surrounded by S and P is calculated by the formula: $V=\frac{\pi ab}{2}\left(-\frac{n_0}{n_3}+\frac{a^2n_1^2+b^2n_2^2}{4n_3^2}\right)^2$, where $n_1=\frac{a_1}{\sqrt{a_1^2+b_1^2+c_1^2}}$, $n_2=\frac{b_1}{\sqrt{a_1^2+b_1^2+c_1^2}}$, $n_3=\frac{c_1}{\sqrt{a_1^2+b_1^2+c_1^2}}$, $n_0=\frac{-d_1}{\sqrt{a_1^2+b_1^2+c_1^2}}$. This formula was obtained by V. V. Shelomovskii and Wei-Chi Yang in [3].

We program a MATLAB procedure "quadravol" based on above formula, the procedure will calculate the volume we desire if we input the equations of a quadric surface and a plane.

A Example

Example 1 Let S be the surface $x^2+y^2+5z^2-6xy-2xz+2yz-6x+6y-6z+10=0$, and P be the plane $3x+8y+5z-28=0$. Find the volume bounded by S and P.

Solution: Set up an M-file 'ex1'.

```
f2=@(x, y, z)(x.^2+y.^2 + 5*z.^2-6*x.*y-2*x.*z+ 2*y.*z-6*x+6*y-6*z+10); g2=@(x, y, z)(3*x+8*y+5*z-28);
implicitsurf(f2, [-8, 10], [-8, 8], [-5, 5], 50);
hold on
implicitsurf(g2, [-8, 10], [-8, 8], [-5, 5], 50);
hold off
axis equal
aa=[1 -3 -1 -3; -3 1 1 3; -1 1 5 -3; -3 3 -3 10]; pla=[3 8 5 -28];
quadravol(aa, [3 8 5 -28])
>>ex1
The quadratic surface is a two-sheeted hyperboloid.
The volume bounded by the plane P and the surface S is 2.994272e+001.
```

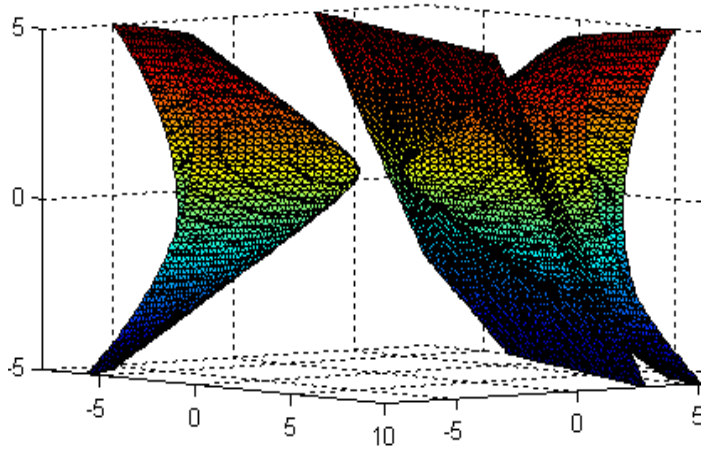

Fig 1 The figure of example 1

Summary

In this paper, we summarize a basic method of calculating volumes of a solid surrounded by a quadric surface and a plane, the method is suitable to programming. We programmed a MATLAB procedure with formal parameters for computing the volumes. It is essential to point out that one need to draw a figure of the quadric surface and the plane to confirm the solid bounded by them with finite volume before using the function. The only one thing to do for users is to input the parameters of a quadric surface and a plane, the function will automatically judge the type of the quadric surface, and output the volume we desire if the quadric surface and the plane may surround a finite solid. Some illustrative examples are given, it is impossible to calculate the results in this paper without the help of MATLAB.

A New Defogging Algorithm Based on Atmospheric Degradation Physical Model

Xiao-Guang Li

Department of Electrical Engineering and Automation, Luoyang Institute of Science and Technology, Luoyang, 471023, Peoples R China

email: lylglxg@163.com

Keywords: Fog-degraded Images; Atmospheric Scattering Model; Fitness Function

Abstract. Aiming at the degeneration phenomenon of images taken in mist, according to features of the drop quality image, this paper proposed a novel defogging algorithm based on improved atmospheric scattering model. The problem of fog-degraded images defogging restoration is transformed into the problem of optimization estimation for original un-degraded image by maximizing the global contrast object function, in this way, the proposed algorithm can restore the object image as completely as possible in probability sense. The experimental results show that the method can effectively improve the fog degeneration phenomenon and improve image clarity, significantly improving drop quality image visual effect.

Introduction

Fog makes outdoor scene image contrast and color will change or degrade, it brings great interference to current vision systems, which brings great difficulties to the outdoor testing, monitoring, automatic navigation, target tracking etc, and therefore the study of fog degraded processing algorithms has practical significance in general[1].

Currently, the defogging algorithm is divided into two types: the non-model of the algorithm and the algorithm based on a physical model. Typical non-model approach has histogram equalization, wavelet transform, homomorphism filtering and retinex method etc [2]. These algorithms only can improve the image quality relatively and can not achieve the defogging in the true sense [3]. The degradation of the physical model algorithm based on the atmosphere can get relatively good effect to defogging，but its characteristics is in need of getting the depth of information of the scene, it often needs the help of the radar altimeter to obtain depth information, then uses the image data and the depth information together to solve the model parameters, which brings difficulties to the practical application[4]; literature [5] adopts the fog algorithm based on a physical model, but requires two images of the same scene in different weather conditions, an image of a sunny day, as a reference, together with another foggy images obtains the depth information of the scene, which requires a pre-captured image information, and will bring the problem of image matching. It is clearly not practical in many cases.

Recently, more researchers have been devoted to defogging algorithm[6],defogging based on a single image has made great progress, a lot of research based on a single image of dark channel prior[7], the algorithm is established by a prior-model to fogging, directly estimates the concentration in order to achieve high-quality images to the defogging, but the algorithm has benefited from a strong a prior or assumptions, because dark colors is a statistical regular, may be ineffective for some special image, for example, when the scene approaches the air layer essentially and is not covered by shadow, the theory of dark colors is invalid.

The Improved Physical Model

Atmospheric Scattering theory gives the degradation model of fog-degraded Images. The model describes the subject image fog light intensity can be equivalent to the total superposition scene after atmospheric attenuation and the radiation in the environment of the scattered light:

$$E = E_{\alpha} + E_{d} = E_{\infty}(1 - e^{-\beta d}) + Re^{-\beta d} \quad (1)$$

In the model, R is the radiation intensity of the scene under sunny weather ; E_{∞} is the intensity of the sky radiation; d is called the scene depth; β is called atmospheric scattering coefficient, from atmospheric scattering perspective, Eq(1)is called atmospheric scattering physical model. In order to effectively achieve the goal of an image to defogging, it requires improving the fog-degraded image restoration model. An improved degradation unified mode of fog degraded image is put forward. By observing a large of degraded images, we found that although the shooting scene in the whole atmospheric scattering coefficients is consistent with the hypothesis in which can not always be met, but for the target object in the scene at the same depth, it is possible that the assumption is met. Thus, according to the atmospheric model, we obtain an important conclusion, which is located in any area of the scene point on the same depth, which corresponds to the model E_d and E_{α} are constants. so we get the following improved image degradation model, namely，

$$E_i = \omega_i E_{i0} + (1 - \omega_i) E_{\infty} \quad (2)$$

Here $\omega_i \in [0,1]$, because the model is got under the assumption at scenic spot of the same depth, it can realize the recovery on the single image scene of the same depth; therefore we are also call type (2) as the degradation model of the depth. Improved model of the same depth means on the same depth area, the brightness of the arbitrary field spots can be expressed as the true brightness of clear weather and the current weight and the sky brightness. Because of the global scene depth approximate consistent image can be seen as muti-depth images of special circumstances of muti-depth, therefore, the improved united model is put forwarded:

$$E = \varpi E_0 + (1 - \varpi) E_{\infty} \quad (3)$$

The dimension of the vector is the number of images in the same depth zone, such as on the depth of an approximate contains four with area of image to defogging, only to solve the weight vector composed by four weight coefficient. this way through the improvement of the model, it will implement that the complex problem about degraded fog image transfer into simple problem of solving the weight vector composed by several coefficient.

The New Optimization Algorithm Based on Improved Model

The new algorithm based on the improved atmospheric scattering physical model to realize defogging, which need to meet certain goals under optimal parameters for solving the model. For this reason, this paper proposes a novel defogging algorithm. The restoration problem is transformed into the improved model weight vector parameters for solving the optimal problems.

The preprocessing of regional segmentation. When the improved unified atmospheric scattering physical model is used, we must first preprocess the depth region segmentation to the fog-degraded image, the purpose of the regional segmentation mainly determines the dimensions of the new model of weight vector, basis primarily on degraded image segmentation is different on each target depth in which all the pixels on the image, that the division of the degraded image area through the scene is divided into several areas of different depths. Segmentation methods are based on the boundary of image segmentation, and based on region, and based on the based on gray-scale. Through deep segmentation preprocessing, we determine the number of the image with depth in the area, in order to further determine the weights in the vector parameter values, this paper proposes an algorithm for the global optimum contrast of the model parameters based on the sense, this algorithm makes full use of the efficiency and fast and strong robustness of the genetic algorithm advantages. Adaptively to achieve the optimal parameters of the model for solving.

Coding is the premise and foundation of application with genetic algorithm to solve the problem; it is also a key step in designing the genetic algorithm. Genetic algorithms based on individual selection, crossover and mutation genetic operation, which searches high fitness individuals, and gradually increase the amount in the group, finally to seek out the problem of the optimal solution or approximate optimal. Coding quality directly affect the selection, crossover and mutation genetic

algorithm, therefore, how to design a perfect coding scheme for the specific problem has always been one of the difficulties of the application of genetic algorithm, people put forward various coding method, mainly include binary code, gray code coding and floating-point coding method, etc.Due to the improvement of fog drop quality, and the weight parameters in the image degradation model are within the scope of [0, 1], so the floating-point coding method to encode.

Using fitness in genetic algorithm to measure the concept the stand or fall of the individuals in groups, namely the optimal solution of the optimization calculation reaches the fine degree, it also known as the evaluation function and fitness function which is determined according to the objective function. It should first determine the fitness function of genetic algorithm to determine the image quality evaluation standard. Contrast as an important feature of image, it refers to the image of one of the most light gray and dark gray difference between range.

Experimental Results and Performance Analysis

In order to verify the effectiveness of the new algorithm based on improved physical model, the author takes a large number of experiments based on MATLAB platform.Aiming at the image of heavy fog weather conditions, experimental results of defogging shown in Fig1.From Fig1(b) to fog effect can be seen that after the algorithm processing image to fog effect is good and natural color.

(a) The fog-degraded image in heavy fog (b) The defogging effect of new algorithm

Fig.1 Experimental results comparisons of defogging

In order to verify the superiority of the new algorithm, the author uses a variety of algorithms, such as histogram equalization algorithm, single scale Retinex algorithm, compared with the new algorithm, experimental results of defogging shown in Fig2. Fig2 (b) is processing results after dealing with the histogram equalization algorithm. it is thus clear that gray scale image is reduced, obviously, it is not the results we expect.Fig2(c) is processing results after dealing with single scale retinex algorithm, Experimental results have little good, but there is no obvious advantages when handling image contrast, although there are obvious enhancement after processing boundary, but cannot eliminate the "fog" feeling.Fig2(d) is processing results after dealing with the new algorithm based on improved physical model, fog-degraded image is enhanced in different degree, it can reduce noise effectively, and at the same time, with a little loss of image detail.

Fig.2 The comparison of various algorithms to mist effect

Conclusion

The paper combined with the characteristics of the image scene depth distribution, improved the fog image degraded model and proposed a novel defogging algorithm based on the improved model. The new algorithm uses good global search ability of the genetic algorithm and will implement the transfer from the scene defogging problem into the optimal estimation problem to the original and degraded images under global contrast optimal point. The experimental results show that the algorithm of defogging can not only realize the processing to single degraded image clearly, obtain ideal visual effect, but also can realize simply due to avoid solving the complex parameters such as depth and atmospheric scattering coefficient and so on.

Abstract. For the problems that the street running state and information was difficult to feedback and reasonable control, we apply the topology model to the street lighting management system, and complete the optimization control in this paper. Using the fuzzy control theory to handle the road signals, the intelligent lighting region controller integrates the thyristor chopper with the autotransformer technology, carries out the soft start and slow slope control to the street light, and realizes automatic voltage and energy saving. At finally, the system can realize the energy-saving control and intelligent, networked management of city street lamp.

Introduction

In order to improve teaching methods, to make better use of modern method and further improve the quality of teaching, students' evaluation of teaching has been more and more widely used in college. If teachers cannot be assessed and evaluated comprehensively and scientifically, the positive effects will be fallen back, which the negative functions will highlight. In recent years, schools are in the implementation of "students' evaluation of teaching". However, because of the unreasonable processing of evaluation results, the process of teaching evaluation often exists in name only. This paper uses fuzzy method to solve the problem of result processing. This method can give a relatively accurate result of the evaluation tables.

Principle of Fuzzy Method

Fuzzy method is proposed by L.A.Zadeh in 1995. The basic principle is as follows: To evaluate a variety of factors of one thing, firstly, we should divid the factors into some big factors according to a particular attribute, and then synthetically evaluate the big factors juniorly, then seniorly synthetically evaluate the results of junior results. The evaluate process using single level model is generally as follows.

1. Build the factors of evaluated object

Propose $u_i\left(i=1,2,\cdots n\right)$ is the factors of the evaluated object. We can express the factors as follows:

$$U=\left\{u_1,u_2,\cdots u_n\right\} \tag{1}$$

Factors are the attributes or performances of the object. The factors can express the quality of the object. The factors in this paper is the evaluation index.

2. Build the evaluate results of the evaluated object

Propose $v_i\left(i=1,2,\cdots m\right)$ is the evaluate result of the evaluated object. We can express the results as follows:

$$V=\left\{v_1,v_2,\cdots v_m\right\} \tag{2}$$

The results could be some datas or some words. That is the results could be fuzzy or non fuzzy. But their relationship with the results is clear.

3. Build the sigle factor evaluate matrix

For a single factor u_i, it has a degree of importance to the evaluate results, which is called membership to the results. The membership is marked as $r_{ij}\left(j=1,2,\cdots,m\right)$. The single factor evaluate matrix is marked as R.

$$R=\begin{vmatrix} r_{11} & r_{12} & \cdots & r_{1m} \\ r_{21} & r_{22} & \cdots & r_{2m} \\ \vdots & \vdots & \vdots & \vdots \\ r_{n1} & r_{n2} & \cdots & r_{nm} \end{vmatrix} \tag{3}$$

4. Determine the weight of evaluation factors

Objective weights are very import for the evaluate process. Generally we compose the weights using statistics experiment. Propose the weights is $A=\{a_1,a_2,\cdots a_n\}$.

Where $\sum_{i=1}^{n} a_i=1, a_i\geq 0$ (4)

5. Fuzzy comprehensive evaluation

When A and R is known, we can get the fuzzy evaluate as follows:

$$B=A\cdot R \tag{5}$$

Where $B=\left(b_1,b_2,\cdots,b_m\right)$ which is called fuzzy evaluate results. If $\sum_{i=1}^{m} b_i\neq 1$, it should be normalized by the formula

$$B'=\left(\frac{b_1}{\sum_{i=1}^{m} b_i},\frac{b_2}{\sum_{i=1}^{m} b_i},\cdots,\frac{b_m}{\sum_{i=1}^{m} b_i}\right) \tag{6}$$

Evaluate Experiment

Now we use the evaluate method to evaluate the effect of teaching.The factors is $U=\{u_1,u_2,u_3,u_4\}$. u_1 is the level of teaching. u_2 is teaching attitude. u_3 is teaching method. u_4 is the teaching ethics. The results is $V=\{v_1,v_2,v_3,v_4\}$, v_1 is excellent. v_2 is good. v_3 is middle. v_4 is pass. The weight of evaluation factors is $A=\{a_1,a_2,a_3,a_4\}$. According to the statistics experiment, we can give the values as $A=\{0.4,0.3,0.2,0.1\}$.Then we statistic the results from students. For example, from one class, to the single factor level of teaching, 30 percent of the sutdents gives excellent, 45 percent gives good, 20 percent gives middle and 5 percent gives pass. So to the factor u_1, the membership is $\{r_{i1},r_{i2},r_{i3},r_{i4}\}=\{0.3,0.45,0.2,0.05\}$. So the fuzzy comprehensive evaluation result is

$$B=A\cdot R$$

$$=(0.4,0.3,0.2,0.1)\begin{bmatrix} 0.3 & 0.45 & 0.2 & 0.05 \\ 0.4 & 0.4 & 0.1 & 0.1 \\ 0.35 & 0.5 & 0.1 & 0.05 \\ 0.5 & 0.4 & 0.1 & 0 \end{bmatrix}$$

$$=(0.36,0.44,0.14,0.06)$$

Normalized result is $B'=B=(0.36,0.44,0.14,0.06)$

From the result we can get the quality of classroom is good.

The above example is a simple experiment of low dimensionality. When the dimension is large, the calculation will be more complicated. But the basic priciple is the same as the above example. In fact, there are a lot of students evaluating teachers' index. Generally, the level of teaching is composed by content of courses, teaching ideas, teaching schedule, blackboard design, personal ability and so on. Teaching attitude is composed by preparation conditions, affinity degree, punctual, serious and so on. Teaching method is composed of interaction between teachers and students, inspire students, humor, using multimedia and so on. Teaching ethics is composed by be a model for others and strict management. We call this two level index.

In this condition, we should first calculate the scores for the factors. For example, the weight of u_1 evaluation factors is $A_1 = \{a_{11}, a_{12}, a_{13}, a_{14}, a_{15}\}$. Suppose the scores is percentile. The statistical membership is got. We can get the u_1 score of one student by:

$$C_i = \sum_{i=1}^{5} a_i s_i$$
$$= 0.25 \times 90 + 0.2 \times 87 + 0.2 \times 95 + 0.2 \times 98 + 0.15 \times 82$$
$$= 90.8$$

So the score is calculate as excellent. Calculate the scores of every student to get how many student gives excellent, how many gives good, how many gives middle and how many gives pass. They are recorded as r_1, r_2, r_3, r_4 ,so we can get the $\{r_{i1}, r_{i2}, r_{i3}, r_{i4}\}$ as

$$r_{i1} = \frac{r_1}{r_1 + r_2 + r_3 + r_4}, \quad r_{i2} = \frac{r_2}{r_1 + r_2 + r_3 + r_4}, \quad r_{i3} = \frac{r_3}{r_1 + r_2 + r_3 + r_4}, \quad r_{i4} = \frac{r_4}{r_1 + r_2 + r_3 + r_4}$$

Then use the method above to get the finally score of a teacher.

Of course, we can give more index for the scores to describe a teacher's grade more accurately. The Method of performance evaluation is a good topic for further study. In this paper, only a simple evaluation results are given. The evaluation process is the focus of this article.

Summary and Ackowledgement

Fuzzy method can gives a relatively accurate result for the evaluation of teaching quality process. To make the students' evaluation of teaching more comprehensively and scientifically, this paper chooses fuzzy method to calculate the evaluation result. Relatively accurate result can make the teachers better know about himself and make the teaching process more effectively.

I would like to express my gratitude to all those who have helped me during the working of this thesis. I gratefully acknowledge the finding of this study by the Education Science of Jilin Province project(ZC13131 and GH12351).

Keywords: Pairwise NQD; Mutation; Service; Random Variables Sequences

Abstract. We study the strong stability of linear forms of pairwise negatively quadrant dependent (NQD) identically distributed random variables sequence under some suitable conditions. To overcome the weakness of collaborative services ability in different grid portal, a new grid portal architecture based on CSGPA (Collaborative Services Grid Portal Architecture), is proposed. This paper aims to enhance the performance of PSO in complex optimization problems and proposes an improved PSO variant by incorporating a novel mutation operator. The results obtained extend and improve the corresponding theorem for independent identically distributed random variables sequence.

Introduction

PSO is a recently proposed intelligent search technique, which was inspired by the social and cognitive behavior of swarm. As mentioned before, PSO as well as EAs are population-based random search algorithms, which usually start from a set of initial members or particles (called initial population) and towards the global optimum by executing iterative operations. In PSO, each particle has two features: velocity and position. The velocity determines the step size of movement every generation, and the position represents a candidate solution in the search space. Every generation, PSO utilizes a velocity and a position updating equation to recalculate the new velocity and position of each particle. When a particle moves in the search space, it remembers its previous best position (called pbest) and the global best position (called gbest) found so far. PSO's social and cognitive behavior is based on these two particular particles. The grid is a giant supercomputer of high efficiency, which integrates the distribution system and heterogeneous computing resources, and it provide the full sharing of computing resources, storage resources, data resources, information resources, knowledge resources, expert resources, and equipment resources. Grid Service is the use of grid services for users. In this paper, GDT is used to establish the database grid service for handling and processing the distributed, heterogeneous database.

At present, data of each application fields is increasing at an amazing speed. In the real application environment, most of massive databases exist in the form of distribution. If the distributed data was concentrated into a data warehouse for mining deal, it will pose a threat to the distributed data's security and privacy, and further reduce the efficiency of mining, but also make a higher requirement of network communication bandwidth. It becomes an urgent requirement to achieve sharing among the distributed and heterogeneous database resources.

Database grid service can support high-performance needs and data distribution well, and store, manage huge amounts of data more effectively, and analysis and handle a large number of heterogeneous distributed database resources more efficiently. Database grid service has many applications features, such as data-intensive, data resource diversity and heterogeneity, large-scale collaboration with the local control rather than global control, data security, load balancing of data resource access, etc. Clients interact through the appropriate database grid services and data service resources. The database grid encapsulates the function that need to use Web Service interface to open data services resources.

The notion was proposed by statisticians Lehmann[1] in 1966, pairwise NQD sequences form an important class of dependent random variables and have wide applications in probability, statistics,

finance, economy and other subjects and real problems. Usually, the independent random variables sequence is special case of pairwise NQD sequence, so it is more difficult to study pairwise NQD sequence. Some authors have studied pairwise NQD sequences and a great number of papers on them appeared in literature. For example, Lehmann[1] discussed the applications of pairwise NQD sequence in statistics, Matula[2] gave the Kolmogorov-type strong law of large numbers of sums of pairwise NQD sequences, which were the same as independent sequences case. Wu[3] extended the Kolmogorov-type inequality to the case of pairwise NQD random sequences, and studied the convergences properties of pairwise NQD sequences by Borel-Cantelli lemma. Wan[4] and Zhang and Wang[5] studied the law of large numbers and the complete convergences, the results obtained were the same as independent sequences case. Chen[6] studied the Kolmogorov-Chung type strong law of large numbers for pairwise NQD random sequences. By the promoting of strong law of large numbers, and considering the compatibility of least squares estimation of the linear model, it is need to discuss the strong stability of linear forms, so many authors discussed it. Wan and Chen[7] discussed the strong stability of linear forms with pairwise NQD random sequences by the properties of pairwise NQD random sequences, Borel-Cantelli lemma, kronecker lemma, the results were as follows as Fig.1.

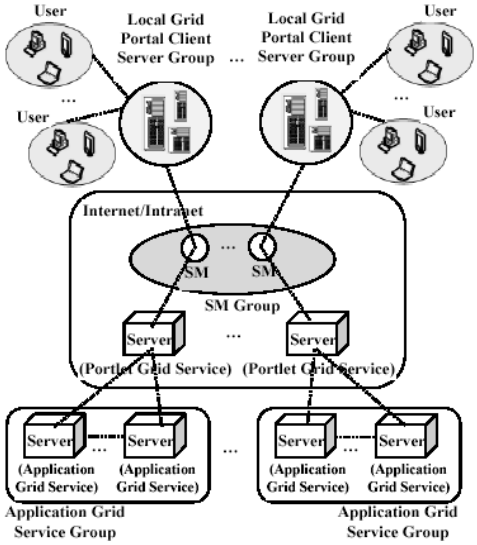

Fig.1 Application system architecture based on Identical Distributed Pairwise NQD Random Variables Sequences (IDPNRVS)

Database Grid Service Introduction

The architecture of collaborative services grid portal is shown in Fig.2. Its operating mechanism is as follows.

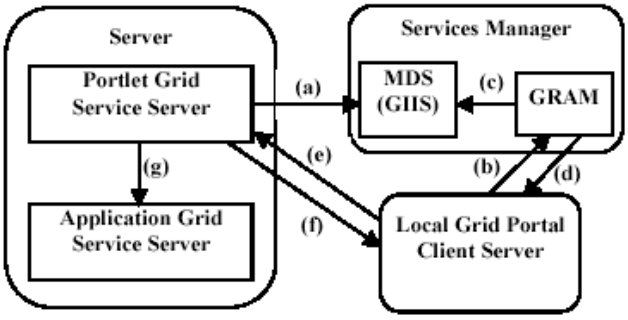

Fig.2 Architecture of CSGP

Hardware Circuit Design

The Central Processing Unit (CPU) applies the industrial chips of MC9S08 AC16, which are industrial eight-digit single-chip microprocessors with ultra-low power consumption. This type of

chips internally integrate a 16K-byte FLASH and a1k-byte RAM memory with SPI interface, A/D conversion circuit. System framework based on multi-layer network architecture is shown in Fig.3.

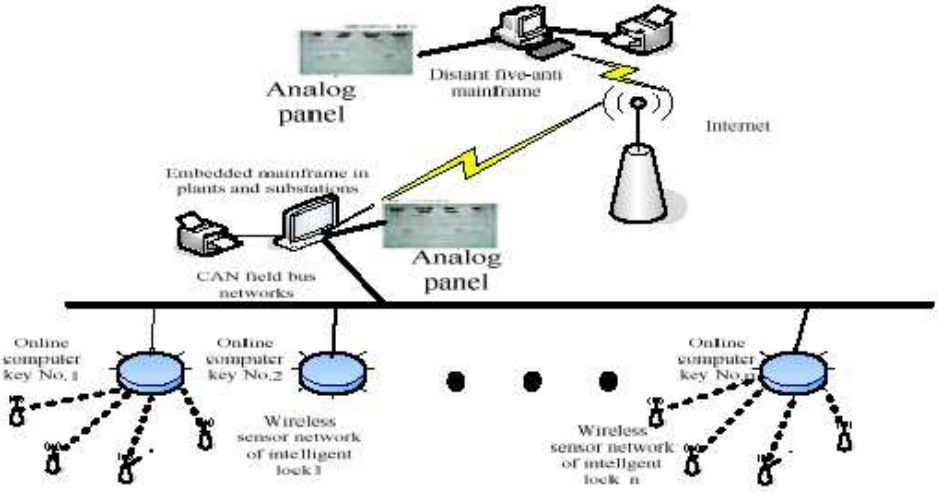

Fig.3 System framework based on multi-layer network architecture

CC2430 has small number of external components. It employs an unbalanced antenna to connect the unbalanced transformer so as to make the antenna have better function.

The parts of hardware in detail are designed as Fig.4.

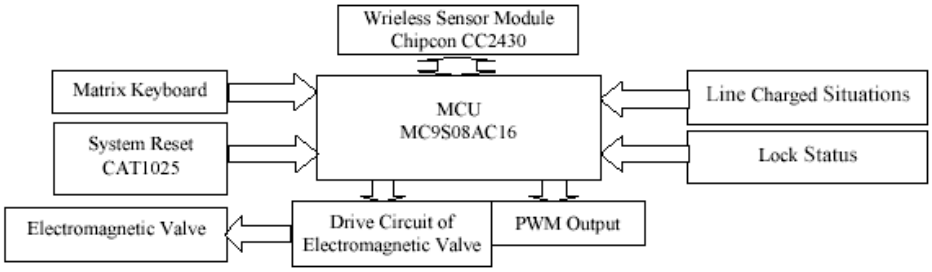

Fig.4 Hardware system framework

In the collaborative services grid portal architecture, a server can allow running many Port let grid services, and of course, the whole architecture also allow existing many Port let grid services which provide the same function, some Port let grid service can access the corresponding one or more application grid service. By this means, Port let grid service can mainly process the display logical. Port let grid service provide an interface service to the terminal users of the grid portal, while the gird resource that terminal users need to access and use, is provided by the application grid service running on the other server. In this way, we can separate the display logic from the application logic in grid portal better. In the whole grid portal system based on collaborative services grid portal architecture, the amount of the servers of running Port let grid service can be dynamic change, but they don't have the close connection between the each Port let grid service server, so any one server goes wrong, it will not influence the normal operation of the whole architecture. To the requestors, because of each Port let grid service is developed based on the standard, so the requestors are very convenient to plug Port let grid service in grid portal itself by configuration, and don't need to add other program code.

Conclusion

In the theorems of this paper, we study the strong stability of linear forms in identically distributed pairwise NQD random variables sequences, and get sufficient conditions of strong stability of them by the truncation in random variables. The theorems in this paper extend and improve the corresponding theorems for independent identically distributed random variables.

Collaborative services grid portal architecture is presented in this paper. Through our study, analyze and evaluation contrast to the architecture, we can find that the architecture is clearer than some current grid portal architectures, and it improves the scalability and reusability of the grid portal. The emphases of next step work are to solve the dispatching problem in the case of the large number of concurrent and the many-to-many relationships problem of grid service.

Keywords: Failure Detection; Design; Zadoff-Chu Sequence; Wireless-Optical Broadband Access

Abstract. HF channel sounding requires perfect autocorrelation property of the sounding sequences. Compared with other pseudonoise sounding sequences, Zadoff-Chu sequence gets great attention due to its predominant periodic autocorrelation property. A Wireless-Optical Broadband Access Network (WOBAN) is gaining more attention because its good performance and merits such as reliability, robustness and high capacity as well as flexibility. There are many factors that can affect the network performance, such as delay, packet loss and capacity utilization. Application examples show that, this system can significantly improve the efficiency of aerodynamic design.

Introduction

Currently, with the growing demand for development of space resources and increasingly fierce competition of commercial satellite launch market, the next generation launcher with high-performance and low-cost is becoming research focus in many countries. Modular design is considered to be the future direction of launch vehicle. It decomposes the launcher into several standard modules. By combing different modules, various capabilities launch vehicle would be assembled to meet different payload requirements. Therefore, the development cycle will be significantly shortened, the costs will be lower, and reliability will be enhanced. Aerodynamic performance of launch vehicle mainly depends on their shape exposed to the air. It also affects other characteristics of launch vehicle, such as trajectory, flight stability, mechanical properties, etc. R&D of Launch vehicle is facing combinatorial explosion problem caused by modular design. That is to say, the possible number of launch vehicle is much more than the number of modules.

A Wireless-Optical Broadband Access Network (WOBAN) is a hybrid of wireless networks and optical networks [1] with passive optical networks (PON) in its backend and wireless mesh networks (WMN) to supply end users with the access.The head terminal of PON resides at Central Office(CO) which is driven by Optical Line Terminal (OLT), while the tail end consists of Optical Network Units (ONU). ONUs connect to wireless Base Stations (BS) which form a multi-hop wireless mesh networks. Some BSs are called gateway routers, of which the location is critical. The end user sends packets or messages to one of neighborhood BS (or called routers). This BS then sends the packet into wireless mesh of WOBAN. The packet will reach the optical backbone through OLT/OC in the manner of multiple hops. The upstream of WOBAN in the wireless end is anycast while the downstream of WOBAN in the wireless end is unicast. This architecture can heal and organize itself with help of wireless mesh networks. The architecture is shown as Fig.1. Through this combination, WOBAN can achieve the merit of both wired and wireless networks: it obtains the characteristics of reliability, robustness and high capacity as well as flexibility [2]. Because packets need to experience several hops, the architecture is definitely subject to the delay. The larger the mesh of WOBAN, the more hops, thus the more delay generated. To handle the problem of delay, Delay-Aware Routing Algorithm (DARA) [3] is carried out. DARA can achieve better load balancing and congestion reduction. Some other efficient algorithms are also proposed, such as Minimum-Hop Routing Algorithm (MHRA), which is intended to minimize the hop number; Shortest- Path Routing Algorithm (SPRA), which is intended to find the shortest path; Predictive-throughput routing algorithm (PTRA) and Capacity and Delay Aware Routing Algorithm (CaDAR) [4]. Among these solutions, CaDAR is the best algorithm for WOBAN. Similar to other algorithms, it accounts for

delay as its first priority. Moreover, it introduces one new concept: capacity assignment. So it is one optimal solution to find the balance point between capacity assignment and flow assignment. Our objective is to find a solution that can improve the bandwidth efficiency as well as reduce the packet loss[5]. In this way, if one OLT or ONU is down, the algorithm can detect the problem and make self healing to redirect to the adjacent link. Moreover, this algorithm also eliminate the probability that the flow on one link is higher than the threshold, thus ensure the minimum delay.

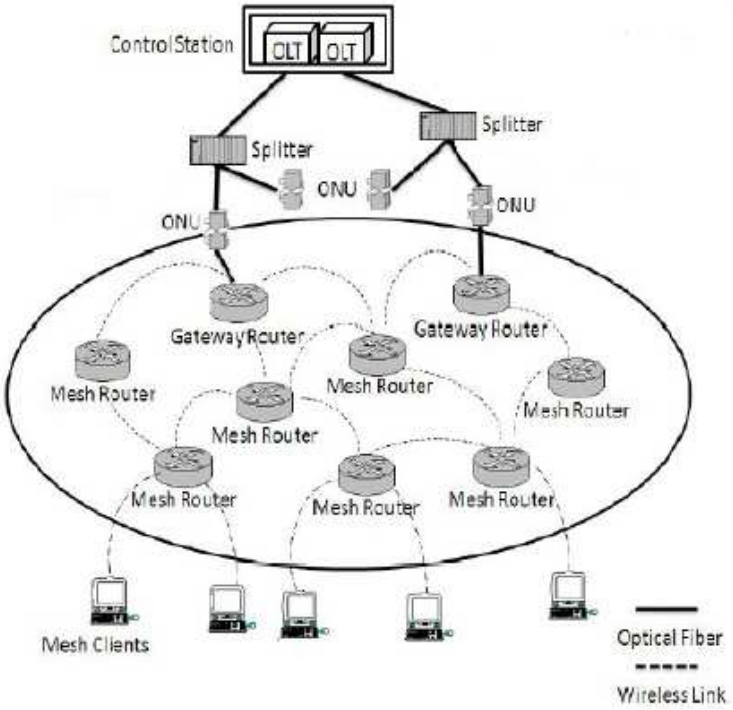

Fig.1 The architecture of WOBAN network

Load Balancing

If we only consider one aspect of the network constraints, other aspects of the network performance pay affect the whole performance. Take delay for example. If delay is the only factor for the algorithm, congestion will occur if most packets select one single link whose link weight is minimum for transfer. We call this load congestion. In our algorithm, we set the link capacity and LSR for each link, which ensures that the load on one link cannot cause the load congestion and also ensures that the network can detect the link failure on time. So FLRAR helps to achieve the load balancing in the network. We show this in Fig.2.

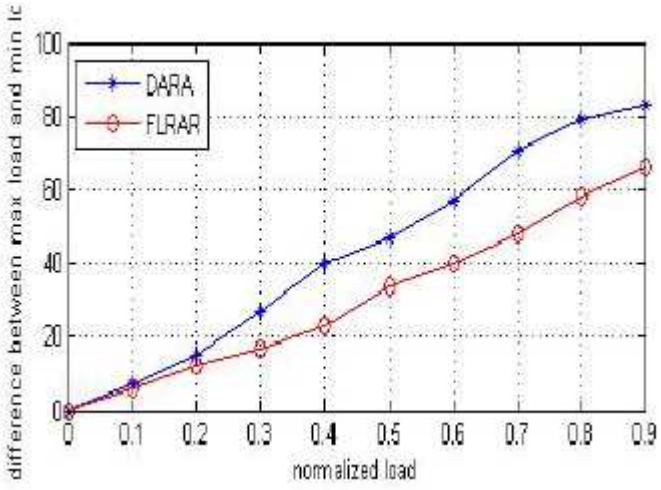

Fig.2 Comparison for load balancing

Motion Control Section

Fig.3 shows the spectra of Zadoff-Chu sequence respectively interpolated by FDIA and commonly used interpolation algorithm with L=1024 and k=1. From the figure we can see that although the spectrum of the sequence interpolated by the commonly used interpolation algorithm is compressed, it has many big side-lobes and rolls off slow. And that the spectrum of the sequence interpolated by FDIA is almost no big side-lobes and rolls off fast. So the sequence energy is centralized, which make it satisfy the bandwidth requirement of HF channel sounding transmitter-receiver.

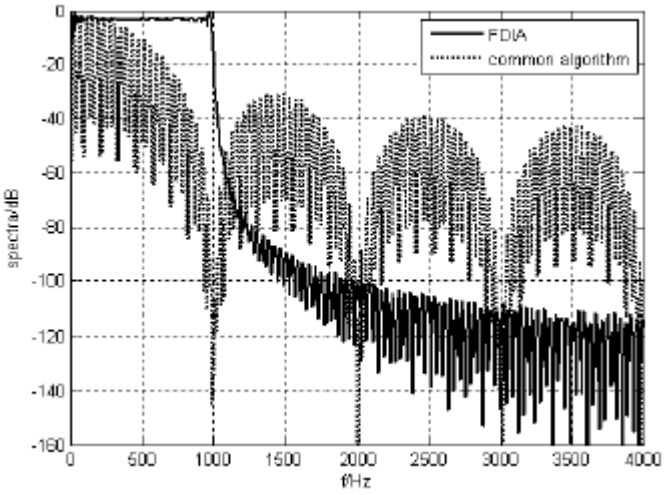

Fig.3 Spectra of sequences respectively inserted by FDIA and commonly used interpolation algorithm

System Software Design

PC software is developed with VC++6.0 that of good interactive interface, enable the system to control in realtime. In motor control section, through the user interface the user can undertake POST (power on self test), path planning, track planning path and so on. The program flow diagram shows as Fig.4. The user can arrange what to do, and how to do because of VC++6.0 based on events programming, with response of events set through good interface, such as when clicked on a button, then the program execute button operation responded.

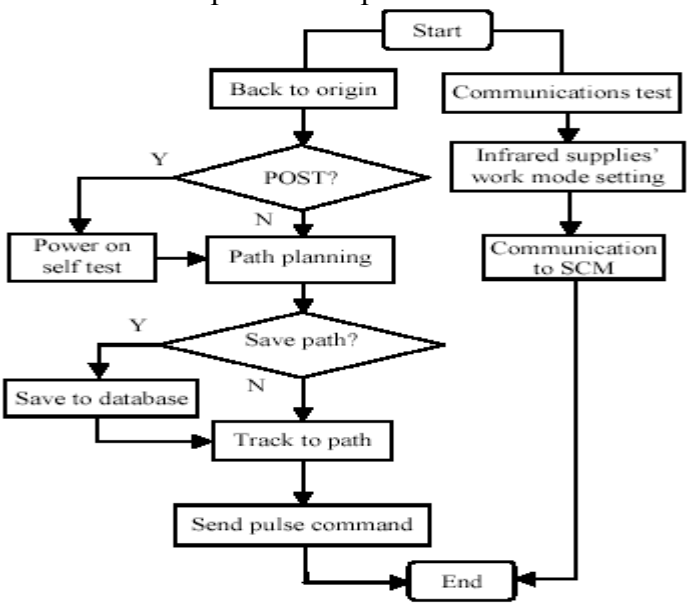

Fig.4 Programm flow diagram

When the program is running, the first to do is initialization, upper computer software communicates with single-chip microcomputer firstly to determine whether it works properly, which

can be shown in the user-interface, at the same time moving infrared light supply under control is carried by slider back into origin to ensure the whole motion correction; Then the user can select POST which can track a predetermined path to check whether the system is working normally. Users can draw route planning with the existing lines, rectangular, circle planning in the picture box of software, after successful design software can save track data in a database, and infrared supply can track the path also in directly. The software can support user-defined trajectory, user select multiple points to draw path planning, which can draw any graphics.

Conclusion

WOBAN is an effective architecture as it combines the merit of both wired and wireless network: reliability, robustness and high capacity as well as flexibility. However, ineffective routing algorithm can cause the declination of the network performance. so it is good to improve the scalability of the network. In HF channel oblique sounding, the selection or design of sounding sequences is a key technique. The paper investigates the periodic autocorrelation property of Zadoff-Chu sequence based on the introduction of the definition and properties of CAZAC sequences. Aiming at resolving the problem that the spectrum of Zadoff-Chu sequence is not band-limited which makes it be not suitable for transmission in HF channel, the FDIA is proposed in the paper by which the amplitude frequency characteristic of Zadoff-Chu sequence can be enhanced. At the same time, an effective method of achieving optimal decimation of the Zadoff-Chu sequence interpolated by FDIA is provided. In the control process, it is convenient to process all necessary parameter setting and adjustment, and in the control process of the whole system shows superior performance and achieves the expected effect.

Keywords: Algorithm; Mutation; Swarm Intelligence; Structure

Abstract. In order to make full use of texture features of image when fusing images, and taking into account the inherent advantages of fractal theory in this respect, a novel image fusion algorithm, which used fractal dimension and directional contrast, based on multi-wavelet transform was proposed in this paper. So, we put forward a new design of the intelligent lock which is mainly based on the technology of wireless sensor network. Particle swarm optimization (PSO) is a recently proposed intelligent algorithm which is motivated by swarm intelligence. PSO has been shown to perform well on many benchmark and real-world optimization problems; it easily falls into local optima when solving complex multimodal problems. Moreover, the objective indexes, which are image entropy, standard deviation and quality measure, were adopted to evaluate the comparative results of evaluating fusion quality. To avoid the local optimization, the algorithm renews population and enhances the diversity of population by using density calculation of immune theory and adjusting new chaos sequence.

Introduction

Fusion algorithm decomposed original images needed to be fused by multi-wavelet transform firstly, then fractal dimensions of the corresponding decomposing low-frequency coefficients were calculated by Differential Box Counting method, and the low frequency fusion rule based on fractal dimension was set up. The high frequency parts were fused by selecting method or weighted averaging method according to the directional contrast values. The fusing experiment using this algorithm to IR image and visible light image was done. In order to illustrate the performance of the algorithm, particularly the impact of introduction of fractal theory on the fusion performance, the result of those fusion algorithms that only uses multi-wavelets transform were given as well. The results show that the leading of fractal dimension into image fusion processing is effective, and it performs obviously better in increasing the amount of information, the standard deviation and the quality of fused image. Under these situations designing a reasonable on-line computer anti-lock system is an alternative to solve the current problem[1] [2].

The image fusion, which is to synthesize the information from multiple image sensor in multi-levels which are pixel-level, feature-level, and decision-level, aims to obtain the more accurate, comprehensive and reliable image description of the same scene. With the advances in image processing technology and social development, image fusion is playing an increasingly important role in military and civilian fields. There has been a lot of fusion algorithms adopted multi-resolution decomposition idea in the research of image fusion [3][4]. Multi-wavelet transform has the better performance than traditional wavelet transform because of orthogonality, smoothness, symmetry, limited support and other characteristics that multi-wavelet system has at the same time. Fractal theory is a very active branch of modern mathematics and nonlinear science, and it plays a more and more important role in digital image processing[5]. It can be found that there are a large number of research reports on natural image modeling, image texture analysis and so on making use of fractal theory to analyze and study.

This paper proposes an pixel-level image fusion algorithm that combines multi-wavelet transform and fractal theory. Thus, the fusion not only takes the image high frequency and low frequency performance into account, but also the utilization of the image texture characteristics such as

roughness. It results in more comprehensive and scientific consideration for the image information in the fusing process.

Software Design of Intelligent Lock

The wireless sensor modules adopt the independent single chips to control the FR chips, so under the terms of the agreement are met, the software designing mainly consider how to establish the physical link between the intelligent locks as well as between the intelligent locks and on-line computer keys. The wireless transmission of control data and the specific control and inspection operations of the intelligent locks are solved by the application layer software. The software framework of the intelligent locks is shown as Fig.1.

Firstly, the on-line computer key scans for empty information channels to try to establish a new network. Once some empty information channel is found, it will select a random personal area network and start to monitor the channel; now the network is established.

If some operation is to be conducted, the on-line computer key will keep the data frames in indirect-sending buffer until the intelligent lock inquires or is timeout. The intelligent lock will be waken-up periodically and send the inquiry request to the on-line computer key, which will search the indirect-sending buffer. If one frame is found to wait to send to the joint, the on-line computer key will send the frame and wait for confirmation.

Algorithm flow chart is shown as Fig.2.

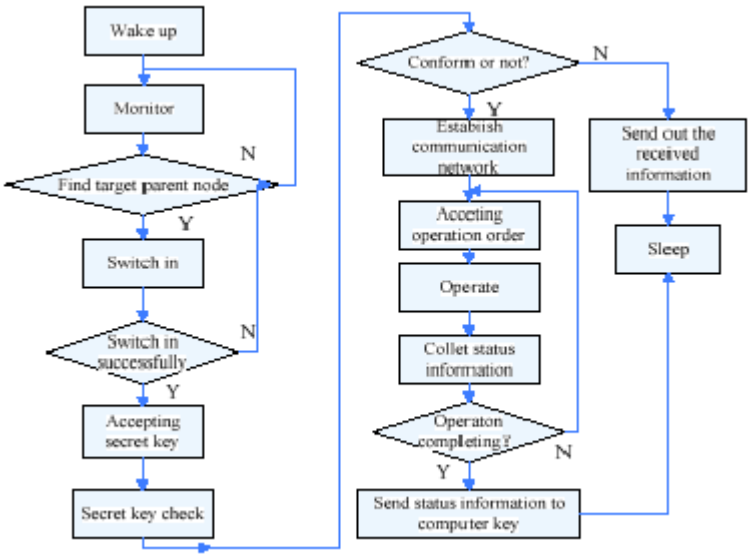

Fig.1 Wireless communication software structure diagram

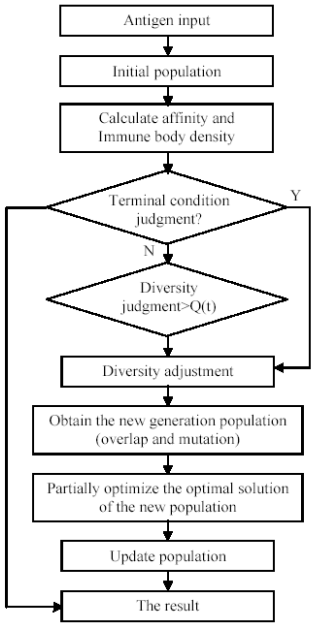

Fig.2 Algorithm flow chart

Scientific Basis for Fractal Theory used for Image Processing

Because fractal set can generate complex natural scenes by simple iterative method and effectively measure the complexity of object through fractal parameters, there is a natural relation between image and fractal. It is the relation that lays the basis of fractal theory using for image processing and opens up a new area of image application. Fractal dimension is a main measurement tool of fractal image processing technology, the most basic mathematical concept in fractal theory, and the most important aspect of the application of fractal theory. As we know, image texture is an important element of image analysis and processing. Image fractal dimension not only measure the complexity of image surface irregularities, but also has the invariance of changing in multi-resolution and multi-scale. It is consistent with the human visual perception of the degree of image surface texture roughness. The bigger the fractal dimension of image is, the rougher the image surface is. On the other hand, the smaller the fractal dimension is, the smoother corresponding image surface is. The experiments of cognitive science of human visual perception

show that people often focus on the degree of rule fragmentation and the profile of features when human eyes perceive the natural target, but neglect its general details. Large numbers of experiments show that fractal model, which has the ability to abstract the regular level of structure of object surface from a large number of varied details and has profound physical background, is a kind of statistical model. It is suitable for describing the research object that has complex and irregular shape. Therefore fractal model is significantly better than the conventional autoregressive and Markov texture model in the expression of low frequency component of image.

Simulation results are shown as Fig.3.

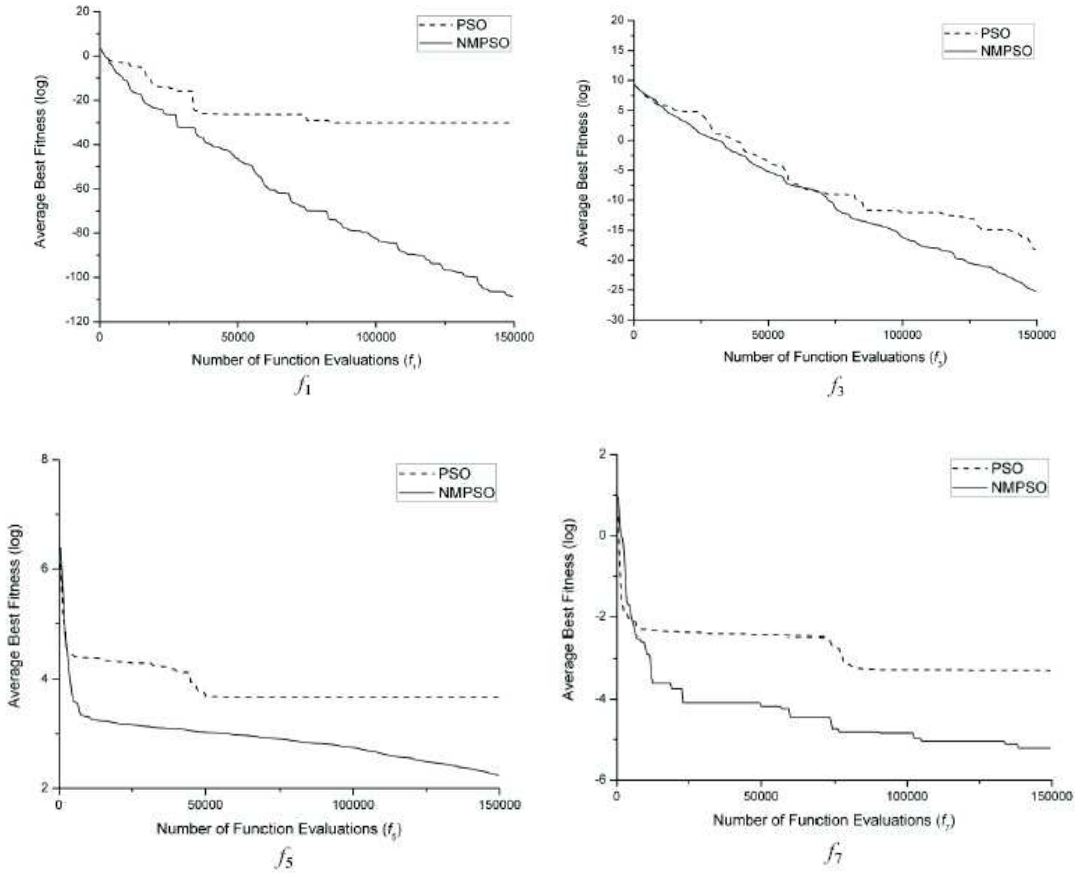

Fig.3 Evolutionary curves of standard PSO and NMPSO on four problems

Directional Contrast in Multi-Wavelet Domain

In order to validate the performance of the proposed fusion algorithm, simulation experiment for infrared image and visible light image was carried out by MATLAB 7.0 platform.

Conclusion

When fractal dimension of image is used to express the degree of irregularities of the image surface, it is consistent with human visual perception of surface texture roughness. Directional contrast of image is accordant with human visual when it reflects the change of image information. Multi-wavelet is able to decompose image into more abundant frequency information than traditional wavelet.

This paper presented a novel fusion algorithm that takes advantage of fractal dimension, directional contrast and multi-wavelet transform. Simulation results show that the algorithm is effective, particularly improves the quality of fused image because of the introduction of fractal dimension. It presents an improved PSO algorithm to enhance the performance of standard PSO. The proposed approach is called NMPSO, which embeds a novel mutation by incorporating with

the search information of the global best particle and other two random particles. It is to hope this improvement can help trapped particles jump to better positions. Simulation results on ten problems show that NMPSO not only achieves more accurate solutions than PSO, but also converges faster. However, NMPSO is not suitable for all kinds of problems, such as f5, f8 and f9, both PSO and NMPSO fail to solve these problems. To improve NMPSO further, we may introduce other search strategies. This will be investigated in our future work.

Keywords: NN; Flywheel Energy Storage; Reluctance Machine; Interpolation

Abstract. This paper presented the key techniques development of motor/generator (M/G) for the FES system in recent years, and summarized the latest developments of three machines such as: induction machine (IM), reluctance machine(RM) and permanent magnet machine (PMM) including traditional structure PMM and Halbach structure PMM, which now widely used in the FES system. The characteristics of three machines had been compared and analyzed, which provides guidance for the FES field researchers to choose appropriate M/G.Then the comparison of spectra of the sequences respectively interpolated by FDIA and commonly used interpolation algorithm is conducted, which affirms the superiority of FDIA. Finally, an effective method of achieving best decimation of the sequence interpolated by FDIA is provided. All these lay primary theory foundation for the application of Zadoff-Chu sequence to HF channel sounding.

Introduction

CAZAC sequence with a length of N^2 (N is an integer) which was used in the Zadoff-Abourezk patent of a synchronizing system was first proposed by Frank in 1950s. The CAZAC sequence proposed by Frank was described afresh by Frank and Zadoff in. Based on the work of Frank and Zadoff, D[1]. Chu proposed a sort of CAZAC sequence without restriction on its length, that is, Zadoff-Chu sequence. And he proved that certain linear phase shift of the form exp(j2 π qk/ N), when introduced into the sequence will not affect its correlation property, where q , k and N are integers, and k is relatively prime to L[2].

In comparison with other ways, it introduced the advantages and the main application of modern high speed flywheel energy storage (FES). It discussed the composition and principle of FES system. Energy storage was an important way for effective utilization of energy, and it was a major direction to solve the energy crisis problem[3]. There were four energy storage modes, including pumped storage, storage battery, ultra capacitor and the FES. In comparison of table 1, we can see the FES has the advantages of long life, high power density, high energy storage densities, basically not be limited by times of charging and discharging, easy installation and maintenance, without pollution etc. So the FES was a new storage technique with wide application prospects. It was last century 50's that FES was used as a means of high-capacity, long time energy storage system, but limited of the technical conditions, until the 90's, the FES technique had entered into a new development stage of the "high-speed flywheel"[4]. It was gradually used in improving the power quality, power grid peak regulation, uninterruptible power supply (UPS), electric car batteries, aerospace, wind power generator and electromagnetic cannon short burst of high power etc[5].

Key Technique of M/G for FES System

The M/G and its control system was the core of the energy converting in a FES device. Wherever the application to, the M/G must combine the character of high efficiency motor and generator. So it needed to have the following advantages as far as possible: The system running in storage, keeping and release mode, what was presented in the last section, it required that M/G was reversible, can running in both motor and make the FES systems become effective energy storage media, which

requested high converting efficiency, high running speed, and the rotor can endure high speed, easy to high-speed operation, good speed regulation performance; In order to improve the load capacity, requested low rotor losses, low no-load losses and high output power, high torque output ability; Required the M/G has long life for uninterrupted operation; Also requested low cost, simple structure, reliable operation, easy maintenance, high power densities, good thermal stability.

Comparison of FDIA and the commonly used interpolation algorithm

Fig.4 shows the real parts and the imaginary parts of the original Zadoff-Chu sequence with L=32 and k=1 and of the sequences respectively 8 times interpolated by FDIA and commonly used interpolation algorithm. The real line represents the sequence interpolated by FDIA and the broken line represents the sequence interpolated by the commonly used interpolation algorithm.

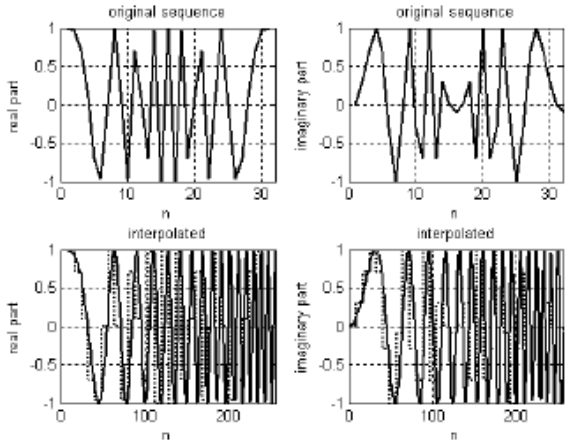

Fig.4 Waves of sequences respectively interpolated by FDIA (real line) and commonly used interpolation algorithm (broken line)

Motion Control Section

Motion control section can be divided into the control part and actuator, which is a classic servo closed loop position control, Motion control section diagram shown in Fig.5. Movement control card can receive PC control instruction, and the axes interface to be controlled send pulses to relevant servo controller to control motor rotation angle, and then ball-screw will convert rotation angle to horizontal displacement, so as to carry the infrared supply horizontal or vertical movement. The control part mainly includes movement control card, servo controller and so on, motor control command is sent through the PC software to regular the movement control card to produce the corresponding output pulse. The whole movement process need two axes motor control respectively, it is adequate for us to use the movement control card supported four axes, and available for circular interpolation, continuous linear interpolation, so the card can meet the equipment requirements. Actuator is a key part of the whole system, which is designed three-rail plane, including two horizontal rails and one vertical rail, ball-screw inside, which can drive the slider with infrared light supply to move in the whole plane. There at the edge of rail separately installs limit switch and origin switch to determine the origin and the maximum boundary. The parts of actuators in detail designed as Fig.6 shows.

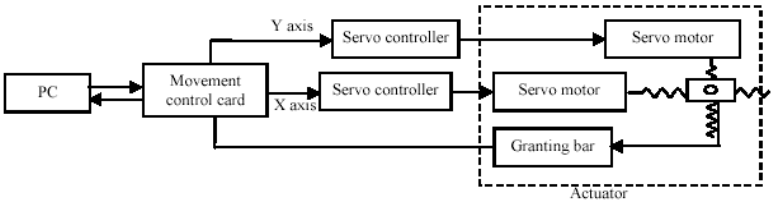

Fig.5 Motion control section

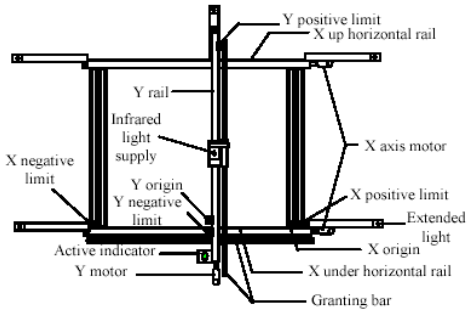

Fig.6 Part of actuator

Neural Network Augmented Model Inversion Architecture

This section details the architecture of the NN augmented model inversion as applied to the tiltrotor aircraft. Fig.7 contains a diagram of the architecture used for implementation of ACAH control in the pitch channel. The command filter serves both to limit the input rate, and as a model for desired response. This allows for straightforward implementation of ADS-33 handling qualities specifications. The presented architecture provides for excellent results in the longitudinal application, as is shown in following sections. Identical construction applies to the lateral channels.

The results in the lateral channels show similar performance.

Conclusion

From that on what had provided principle to select M/G for researchers of the FES system according to difference field or system request. With the rapid development of the FES system, M/G has wide development space, but at the same time, higher request has been put forward for the innovation of the M/G structure and the optimization of the algorithm of the control system.

The spectra of the sequence respectively interpolated by FDIA and commonly used interpolation algorithm have the same main-lobe width, but the spectrum of the sequence interpolated by FDIA has a faster roll-off and almost no big side-lobes, which means that it has a higher energy using ratio when transmission in narrow band HF channel. Hereby, this paper lays primary theory foundation for the application of Zadoff-Chu sequence to HF channel oblique sounding.

In the control process, it is convenient to process all necessary parameter setting and adjustment, and in the control process of the whole system the photovoltaic simulator shows superior performance and achieves the expected effect.

Keywords: Fractal Correlation Dimension; Large Complex Equipment Procurement Plan; Multi-objective Comprehensive Evaluation

Abstract. The multi-objectives of procurement scheme evaluation and the complicated nonlinear are pointed out in this paper according to the definition and characteristics of large complex equipments, and with regard to the defects present in the existing multi-objective comprehensive evaluation method, the assessment method of using fractal correlation dimension as the comprehensive quantitative index of multi-objective decision making in the large complex equipment procurement scheme is put forward, and the efficiency of such method is verified by the example of combat aircraft, which provides a new idea for the multiple objective decision making in the large complex equipment procurement scheme.

Introduction

The concept of Complex Product Systems (CoPS) was comprehensively and systematically put forward firstly by the science and Technology Policy Research Institute (SPRU). Hobday explained that complex product system refers to the products, systems, networks and buildings of high cost, technology intensity, engineering intensity and customer customization.The systems of aviations, aerospaces, shipbuilding, large equipment manufacturing industries and the large telecommunications equipments are classified as complex product systems[1]. Based on Hobday's concept, we define the mechanical equipments such as aircrafts, ships, launch vehicles etc. with customization, complex structures, high technology content, long development cycle, high cost, high risk and complicated management processes as large complex equipments.

The large and complex equipment procurement is of strategic significance to a country, therefore, the balance and decision on the purchasing plan thereof is particularly important. Large complex equipments possess the characteristics of complex customer demand, complex system structure, complex product technology, long development cycle, intensive engineering and information, high input, high risk and customer customization. For the above features, the procurement scheme evaluation of the large complex equipment should not only be focused on effectiveness and costs, which therefore require multi-objective comprehensive evaluation on purchasing scheme.

For the problem regarding multi-objective evaluation and decision, the method of the linear weighted comprehensive assessment are applied mostly. The hotspot for improvement and innovation is also focus on the calculation of the weight [2][3][4] and the precision degree of the index assessment value [5][6], which is still the linear weighting in essence. Therefore, two problems present, one is that the index factors must be independent from each other when the linear weighted method is adopted and the other is that the index and its impact factors have a linear relationship, and the above two conditions are not established generally. Especially for the large complex equipment systems, and the relations there between are intricate where linear approximation method is obviously not suitable. So a new set of the theory and methods are required to solve this problem.

Fractal theory, as the frontier of the nonlinear science study in recently years, reveals inherent law, the hierarchy and scale invariance of various complex phenomena in nature and the human

society, and is applicable to the processing complex multi-level nonlinear relationship, of which the quantitative feature correlation dimension depicts the occupation degree and complexity of the whole to the space and is the quantitative characterization of key information of the whole[7]. However, the basic idea of multiple objective comprehensive evaluation method is to organize a number of individual indexes, to form a comprehensive index contains all sides so as to reflect the panorama of the evaluation object [8] [9]. Obviously, the fractal theory has obvious advantages in dealing with the nonlinear relationship between the evaluation factors and extraction characteristic value of evaluation object. In this paper, in view of the complex non-linear problems in the large complex equipment procurement scheme evaluation index system, we introduce the fractal theory and the multi-objective comprehensive evaluation scheme based on the fractal correlation dimension.

Multiple Objective Comprehensive Assessment Model Based on the Correlation Dimension

Assuming that $A_1, A_2..., A_m$ are the large complex equipment procurement schemes to be evaluated and $K_1, K_2,... K_n$ are n evaluation indexes of the scheme, making x_{ij} (i=1,2,... m; j=1,2,... n) be the j index value of the i scheme evaluation, the dimensionless treatment is conducted according to data standardization methods:

$$y_{ij} = \frac{\left(x_{ij} - \overline{x_j}\right)}{S_j} \tag{1}$$

Wherein y_{ij} is the standard data of origin data x_{ij}, $\overline{x_j}$ is the average value of the j index data and S_j is the standard deviation of the j index data.The procurement scheme evaluation system of large complex equipment composed of the n indexes can be considered as an n-dimensional geometry. The geometry is of unknown internal spatial structure and is irregular. According to the calculation method of correlation dimension:

Firstly, calculate the distance between any two points and record the distance to be $r_{ij} = \left|y_i - y_j\right|$, wherein y_i and y_j are the any two points in n-dimensional index data and the total number points is N=n (n-1) /2. Given an arbitrary distance value r, the number of points corresponding the distance value r_{ij} that is smaller than the distance of r is recorded as $N'(r)$, and the ratio of the two points with the spacing of less than R accounting for all the points is recorded as $C(r)$:

$$c(r) = N'(r)/N \tag{2}$$

$C(r)$ is also known as the correlation function. The following can be obtained by further expansion:

$$C(r) = \frac{2}{n(n-1)} \sum_{i,j=1}^{n} H(r - r_{ij}) \tag{3}$$

Wherein $H(x)$ is Heaviside function:

$$H(r - r_{ij}) = \begin{cases} 1, r \geq r_{ij} \\ 0, r < r_{ij} \end{cases} \tag{4}$$

As can be seen, $C(r)$ is related to the value of r. When r is too small, $\lim_{r \to 0} c(r) = 0$; When r is too large, $\lim_{r \to \max(r_{ij})} c(r) = 1$, and neither of two conditions can reflect the overall internal properties. Adjusting the value range of r, only in the case that r and $C(r)$ have a power law relation, can r correspond to the non scale area of the whole, that is, there exists a value range of r having the following relations, which reflects the overall fractal feature:

$$C(r) \propto r^d \tag{5}$$

Thus it can be seen, whether exists scale-free zone and whether the overall have fractal characteristics depend entirely on the objective fact, and have nothing to do with the subjective judgment.

The correlation dimension can be obtained by the formula (5) where *d* is a good approximation of the correlation dimension *D* [10]:

$$D = \lim_{r \to 0} \frac{\ln C(r)}{\ln r} \tag{6}$$

As can be seen, the calculation of correlation dimension only requires linear fitting at appropriate part of the *lnC(r)-lnr* double logarithm curve, and the slope of straight line segment is the correlation dimension, which can be obtained by using the least squares method:

$$D = \frac{\sum (\ln r - \overline{\ln r})(\ln C(r) - \overline{\ln C(r)})}{\sum (\ln r - \overline{\ln r})^2} \tag{7}$$

Correlation dimension reflects the fractal space filling degree, also reveals the correlation degree of each internal factor. The greater dimension shows the higher association degree of each factor, the more uniform distribution shows the higher occupation degree of overall to the space. While our selection criteria on the optimal scheme belong to the two types of problems in essence: one is to require maintaining coordination and balance between each evaluation index, without any short board; the other is the pursuit of maximum index value at premise of the balance of each index. In the evaluation of the procurement scheme of large complex equipment, the spatial distribution and the overall space filling degree correspond to our two standards for the best scheme. So we can say, the correlation dimension reflects the quality of the schemes in essence. Then, when making the double logarithm curve of *lnC(r)-lnr* of difference schemes, in the presence of self similarity of scale-free zone, we can rank the schemes according to the $D_{good} > D_{bad}$ sequence.

The Example Analysis

In order to test the validity the fractal evaluation tool of the correlation dimension as a comprehensive evaluation method, taking the data of the existing combat aircraft as an example, respectively by the mature method technique for order preference by similarity to an ideal solution(TOPSIS) and fractal comprehensive evaluation method for evaluation. If the results are consistent, there is reason to believe that the correlation dimension evaluation method is reliable. Now we use the existing representative five fighter F-15C, RafaleF2, F/A-22, Su-27SM, EF2000 as an example of evaluation, the basic data of five fighter as shown in Table 1 [11]:

Table 1: The original assessment data of combat aircraft scheme(fiscal 2010, single)

Attribute	F-15C	RafaleF2	F/A-22	Su-27SM	EF2000
Life cycle cost/(FY2010,10^8 $)	2.8568	3.416	6.9517	2.5684	3.197
Availability	0.86	0.85	0.68	0.75	0.88
Dependability	0.3893	0.5394	0.9438	0.4039	0.5198
Integrated combat capability	0.4296	0.5347	0.8366	0.5242	0.5978
Research cycle/month	20	21	24	21	24
Research risk	0.6625	0.6875	0.748	0.655	0.6562
Producibility	0.4973	0.5033	0.3784	0.5872	0.411
Testability	0.88	0.92	0.98	0.86	0.92
Security	0.9682	0.9672	0.9836	0.9643	0.9957
Improvability	0.1693	0.3098	0.4059	0.187	0.2426
Endurance/(flight hour)	7000	7000	8000	6000	6000

After preprocessing of the basic data of the five fighter, the double logarithmic diagrams of *lnC(r)-lnr* are respectively made.Select appropriate regions in the above double logarithmic graph for linear fitting, the fitting equation is:

$$\ln C(r) = c + D \ln r \tag{8}$$

The F-test and T-test are passed, and the obtained data are shown in table 2. As can be seen, the linear fitting degree is basically the same, the coefficient of determination are more than 0.95 and the power law relationship is significantly. According to the fractal dimension of the three aircraft development schemes, the results are sorted as: $D_{F/A-22} > D_{EF2000} > D_{RafaleF2} > D_{Su-27SM} > D_{F-15C}$.

Table 2 Fractal dimension table of evaluation on the three fighter program

	F-15C	RafaleF2	F/A-22	Su-27SM	EF2000
coefficient of determination R^2	0.9582	0.9665	0.9636	0.9626	0.9636
D value	0.7941	1.1035	1.7135	0.9409	1.5087

The technique for order preference by similarity to an ideal solution (TOPSIS) also shied away from simple weighted linear superposition theory, which through measurement of the distance between scheme and the ideal point and negative ideal point, to calculate the relative approach degree, and then to determine the schemes. The specific algorithm refers to document [11] and document [12]. The index weight vectors are $[0.2,0.24,0.052,0.068,0.08,0.064,0.108,0.092,0.096]^T$ [11].Finally we obtain the relative approach degree of $C_{F\text{-}15C}$= 0.3860, $C_{RafaleF2}$= 0.4551, $C_{F/A\text{-}22}$=0.5966, $C_{Su\text{-}27SM}$=0.4136, C_{EF2000}= 0.4891. The sequencing results are $C_{F/A\text{-}22} > C_{EF2000} > C_{RafaleF2} > C_{Su\text{-}27SM} > C_{F\text{-}15C}$, which is consistent with the results obtained through the fractal comprehensive evaluation method and is also consistent with the realistic situation.

Conclusion

This paper introduces the fractal theory into large complex equipment procurement scheme, and puts forward the multi-objective comprehensive assessment model based on fractal correlation dimension. Examples show that, this method is simple and effective, completely based on objective data, without the need of human determination of weigh and can handle arbitrary level of mixed data. The correlation dimension is calculated directly from existing data, without any simplification of comprehensive steps, and the subjectivity is minimized, it is a new method of multi-objective comprehensive evaluation for large complex equipment procurement scheme.

Keywords: ground sense coil; single-phase motors; frequency detection; MCU

Abstract. In this paper, the traffic detection system based on ground sense coil is studied. Due to the change of ground sense coil inductance, the output waveform frequence of LC oscillation circuit changes [1]. The LC oscillation circuit is composed by the three point detection circuit. Then the wave is shaped into a square-wave by shaping circuit. The square-wave is transmitted into MCU, the frequency change is detected by MCU and motor is controlled by control signal from the MCU.So when a vehicle passes above the ground sense coil, this approach makes automobile blockader lift the stop lever automatically. And the system can stop the lever falling when there is a vehicle below the lever, so this system can prevent the vehicle damage. This system can improve practical value and application prospect of a automobile blockader.

Introduction

With the continuous development of science and technology and the progress of the society, automobile has been gradually popularized [2]. In the process of traveling by car, people will inevitably encounter some checkpoints, just like highway toll stations, entrance and exit the parking lot,etc [3]. But there are some problems at these checkpoints, such as artificial duty, low intelligence and low security [4].

This paper is based on the basis of the traditional automobile blockader , then the ground coil is accessed to LC oscillation circuit [5]. When the vehicle passes ground sense coil, the inductance value of LC oscillation circuit changes, and the frequency of the output sine wave changes. The change of the frequency is captured by MCU, thus the motor can be controlled by MCU [6]. If this technique is applied to automobile blockader circuit, there are following advantages:

(1) Achieve unattended, detect the vehicles automaticly

(2) Prevent the stop lever fall suddenly, damage the vehicles

(3) Save cost and improve efficiency [7]

The following works has been done in this paper: introduce the structure and principle of the whole system, design detection device, set up the simulation model, design the motor drive circuit.

The Principle of Vehicles Traffic Detection System Based on Ground Sense Coil

The principle of vehicles traffic detection system based on ground sense coil is shown in Fig.1.

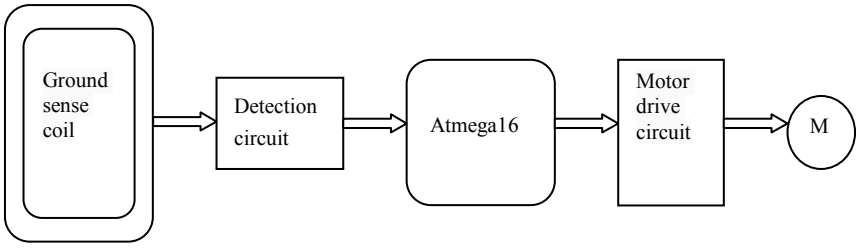

Fig.1 The principle of vehicles traffic detection system based on ground sense coil

Vehicles traffic detection system based on ground sense coil consists of ground sense coil, frequency detection circuit, MCU, motor drive circuit and single-phase motor. Ground sense coil is

under the stop lever. When a vehicle passes above the ground sense coil, its inductance decreases. The ground sense coil is connected to the oscillating circuit, so the frequency of the output waveform increases. In this system Atmega16 is used as the main MCU. There is a input capture function unit in the timing counter T/C1 of this MCU. Through this function a occurrence of external events is able to be captured and the time point is able to be recorded. The frequency change is detected by MCU, when the frequency change is over a set threshold to the MCU. Then the single-phase motor will be drived by a control signal from MCU. Delay link is added to the time of frequency testing. The stop lever is controlled to raise up or fall down by motor. The purpose of automatic detection vehicles is achieved by the above designs.

Modeling And Simulation of Vehicles Detection Circuit

Vehicles detection circuit is designed based on a three-point capacitive feedback LC circuit. Some components parameters are changed based on the range of the inductance change. There are following advantages of this circuit: (1) high-quality oscillation waveform of Capacitive feedback three-terminal circuit; (2) good stability of the circuit frequency; (3) high frequency of the capacitance three-terminal circuit. Vehicles detection circuit is shown in Fig.2.

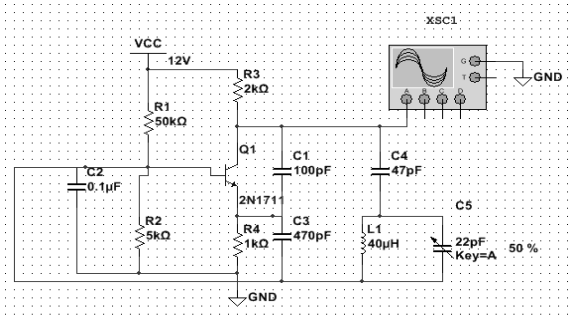

Fig.2 Vehicles detection circuit

The vehicles detection circuit is bulit by the Multisim software. Following information is shown in the picture: the ground sense coil is represented by L1, Sine wave signal is output fome the top of C4.

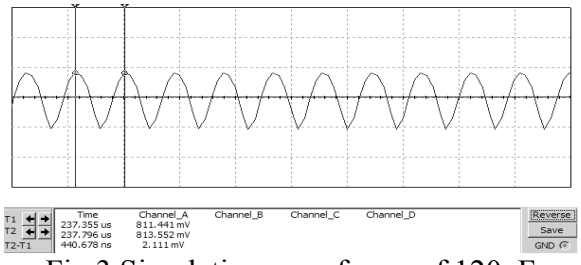

Fig.3 Simulation waveforms of 120uF

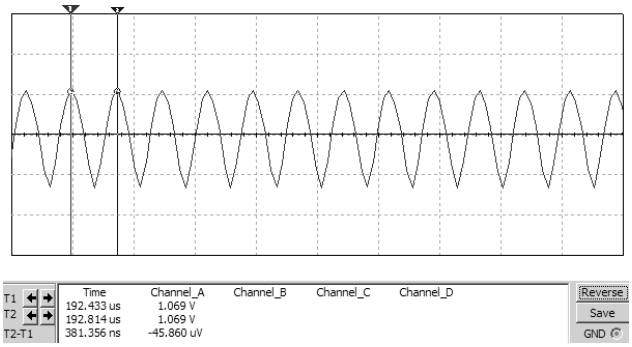

Fig.4 Simulation waveforms of 80uF

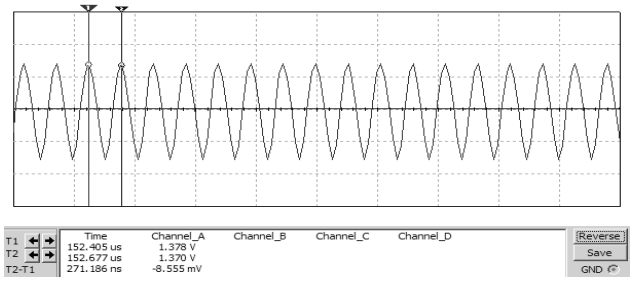

Fig.5 Simulation waveforms of 40uF

Through the simulation waveforms, following information is shown in the it: when the inductance of the ground sense coil changes obviously, the output waveform of the detection circuit obviously changes too.The period of output waveform is reduced nearly doubled when the inductance is changed from 40uF to 120uF. Then the change of frequence is able to detect by MCU. Therefore this mathod is proved to be feasible.

Modeling of Single-phase Motor Drive Circuit

There are several following functions of the single-phase motor drive circuit: (1) converting the control signal from MCU to the drive signal of the motor (2) controlling the motor running, (3) preventing the motor damage with the interlock function.

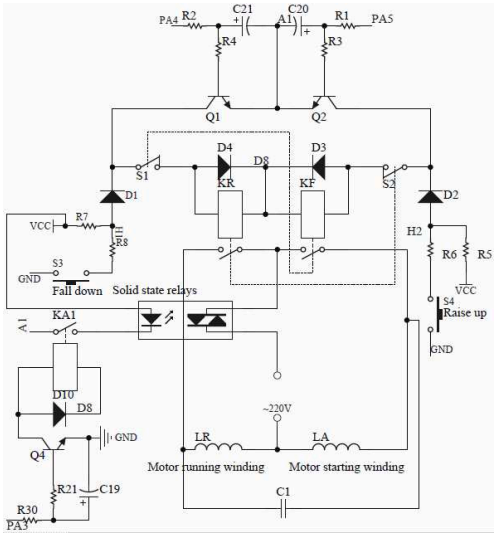

Fig.6 Modeling of single-phase motor drive circuit

Modeling of single-phase motor drive circuit is shown in Fig.6. In Fig.6, the motor is single-phase motor. In order to simplify analysis of the circuit, the motor is represented by two windings. The motor running is controlled by two relays KR and KF. One of the two switching transistors Q1 or Q2 is turned on when a high level is output from PA4 or PA5 of the MCU. Then the relay works which lead to the motor running. In order to achieve the goal of interlocking, a normally closed switch is set in the relay coil loop, the normally closed swich of one relay is opened when the other relay is working.

Conclusions

The traditional automobile blockader is characterized by no intelligent and artificialize. Therefore, a method of vehicle traffic detection system based on ground sense coil is presented. The simulation model of the system has been set up by the Multisim tool based on the working principle. Simulation results show that the system has been successfully applied to the automatic vehicle traffic detection with the demand of raising the lever. It can improve the vehicle traffic detection performance and with high use value and application prospect.

[a]E-mail:yqszb@126.com

Keywords: simulation, dynamic systems, integration package, discontinuity

Abstract. In many techneques for handling discontinuities, the presence of a discontinuity is detected by a change of sign in the value of a discontinuity function. This paper discusses the problems caused by this sign rule of detecting discontinuities for some engineering applications, and describes an alternative which uses a change of the state marker value .The modified program with Runge-Kutta-Merson and Gear integration subroutines have been successfully applied to the simulation for mechanical, electrical and other dynamic systems with discontinuities for which the original program is inefficient.

Introduction

The problem of dealing with discontinuities is often encountered in the simulation of mechanical, electrical and other dynamic systems. Such system are usually described by a set of ordinary differential equations of the form

$$\frac{dy_i}{dt} = f_{ij}(t, y_1, y_2, ..., y_n) \quad \text{i=1,2,…,n j=1,2,…,m}$$

with a set of discontinuity functions ϕ_k (t,y_1,y_2,…,y_n).The finding of discontinuities is in two stages. Firstly, the presence of a discontinuity is detected in an integration step; Secondly, this discontinuity is located as acculately as user specification demands. Generally accepted, the presence of a discontinuity is detected by a change of sign in the value of a discontinuity function[1][2][3][4].

In this paper, the problem caused by this sign rule of detecting discontinuities for some application are discussed, and an alternative which uses a change in the value of a state marker is presented.

The Sign Rule of Detecting Discontinuities

Many techneques exist for handling discontinuities. Although methods of locating discontinuities are various, methods of detecting discontinuities are nearly same.

The Steps of Detecting Discontinuities by the Sign Rule

Generally, steps of detecting discontinuities are as follows.

The discontinuity functions ϕ_k are evaluated at the end of each integration step.

A check is made to determine if change of sign in the value of any ϕ has happened, or a test is made for negative sign in the product $S=\phi_t \times \phi_{t+h}$.

If the sign of a discontinuity function ϕ has changed or the value of S is found to be negative at end of a step ,it indicates a discontinuity somewhere in that step.

If a discontinuity is predicted, its time will be located as accurately as user specification demands. The integration will be adjusted to reach this and then restart. If none is found, the integration will continue normally.

For many cases, this sign rule of detecting discontinuities will be a successful prediction criterion. However, there are three sources which may affect the efficiency of the sign rule for some applications.

The Sources of Affecting the Efficiency of the Sign Rule

One of the conditions $\phi_k = 0$ is necessary but not sufficient for the presence of a discontinuity. Note that a discontinuity location processes consequently as soon as any ϕ passes through zero ,this may raise an extra location.

The sign of the zero value of discontinuity function is indeterminate, an inaccurate result is due to inconsistency in the classification of the sign of the zero value of discontinuity functions in Program's discontinuity detection subroutine and in User's system state condition subroutine[5].

In some applications, the zero value of a discontinuity function has to be distinguished separately;that is, the value of discontinuity functions is distinguished into five class: $>0, =0, <0$, ≥ 0 and ≤ 0.

For some discontinuous systems, these problem as above must be considered. However, it is difficult to do these by the sign rule.

The State Marker Method of Detecting Discontinuities

To overcome the shortcomings of the sign rule, an alternative which uses a change in the value of a state marker is proposed. The philosophical point of this state marker method is that a discontinuity is straightforwardly detected by a change in the value of the system state marker ISTATE. Each value of ISTATE is corresponding to a state of the system. This method steps as follow:

ϕ_k are evaluated at the and of each integration step.

ISTATE is determined by ϕ_k .

If a change of the value of ISTATE is not found, the integration proceeds normally.

If the value of ISTATE is changed, a discontinuity is predicted. A discontinuity location will follow and then the integration will restart under a new state of the system.

Compared with the sign rule, this method can best tackle those problem as described in the previous section.

Program Modifications

Fig.1 indicates a general flow diagram for the modified program.

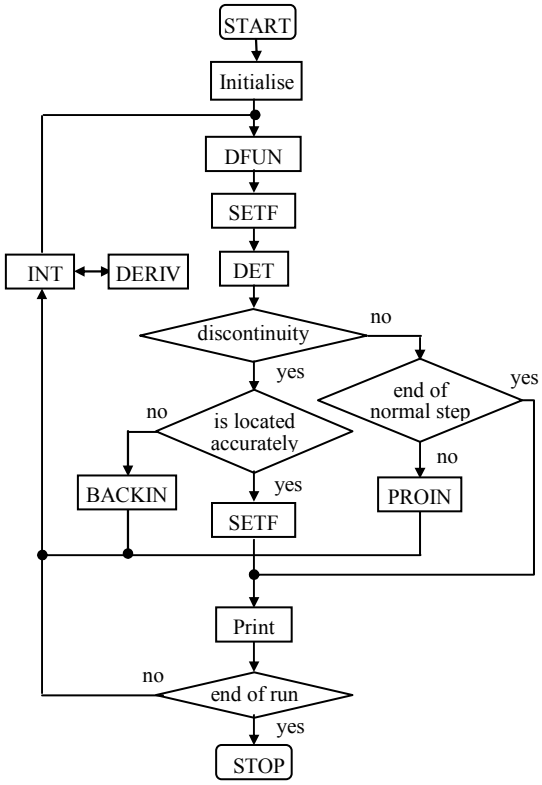

Fig. 1 Program flow diagram

To implement the present method, the small number of modifications to the interpolation subroutine of locating a discontinuity and the main program loop are required. The subroutine DFUN defines the discontinuity functions ϕ_k .The subroutine SETF determines the system state marker values according to ϕ function values.The subroutine EDT indicates a discontinuity by a change of the system state marker values at the end of the integration step. The point at which ϕ passes through zero is located as accurately as user specification demands by the reverse interpolation subroutine BACKIN and the forward interpolation subroutine FROIN. The subroutine DERIV defines the continuous segment state equations corresponding to the system state marker values .The integration subroutine INT can use any standard numerical integration algorithms, such as the standard RK algorithm, RKM algorithm and Gear's Stiff algorithm.

Applications

The modified program with Runge-Kutta-Merson and Gear integration subroutines has been successfully applied to the simulation of some mechanical, electrical and other dynamic systems for which the original program is inefficient. The following example is one of the applications.

Example:The sliding movement of a mechanical object

System model

$$m\frac{dv}{dt}=\begin{cases}0 & (v=0\wedge|f_s(t)|\le Fs)\\ f_s(t)-F_1-F_2v & (v=0\wedge f_s(t)>F_s)\vee(v>0)\\ f_s(t)+F_1-F_2v & (v=0\wedge f_s(t)<-F_s)\vee(v<0)\end{cases}$$

In the formula, parameters:m=0.64,F_s=0.83,F_1=0.75,F_2=0.28

The external force applied to the object :

$$f_s(t)=\begin{cases}0 & (0\le t<0.1)\vee(1\le t\le 1.5)\\ 5t & (0.1\le t<0.5)\\ -t & (0.5\le t<1.0)\end{cases}$$

Initial conditions: $v(0)=0,\quad t\in[0,1.5]$

Define of user's subroutines

To simulate movement characteristics of the system, it is recognized that the system includes time events and state events. According to the state switching conditions of the system equations, the 8 discontinuity condition function can be identified. Therefore three user's subroutines are defined.

The discontinuity condition function subroutine (DFUN) contain:

$\phi_1=t \quad \phi_2=t-0.1 \quad \phi_3=t-0.5$

$\phi_4=t-1.0 \quad \phi_5=t-1.5 \quad \phi_6=v$

$if\ (\phi_1\ge 0\wedge\phi_2<0)\vee(\phi_4\ge 0\wedge\phi_5\le 0)\ \ \phi_7=\phi_8=-F_s$

$if\ (\phi_2\ge 0\wedge\phi_3<0)\ \ \phi_7=5t-F_s\ ,\phi_8=-5t-F_s$

$if\ (\phi_3\ge 0\wedge\phi_4<0)\ \ \phi_7=-t-F_s\ ,\phi_8=t-F_s$

The system state marker subroutine (SETF) contain:

$if\ (\phi_1\ge 0\wedge\phi_2<0)\vee(\phi_4\ge 0\wedge\phi_5\le 0)\ \ TF=1$

$if\ (\phi_2\ge 0\wedge\phi_3<0)\ \ TF=2$

$if\ (\phi_3\ge 0\wedge\phi_4<0)\ \ TF=3$

$if\ (\phi_6=0\wedge\phi_7\le 0\wedge\phi_8\le 0)\ \ SF=1$

$if\ (\phi_6=0\wedge\phi_7>0)\vee(\phi_6>0)\ \ SF=2$

$if\ (\phi_6=0\wedge\phi_8>0)\vee(\phi_6<0)\ \ SF=3$

The system state marker ISTATE is determined by a pair of TF and SF values. Each continuous segment state of the system is corresponding to a pair of [TF, SF] value.

The system state equations subroutine (DERIV) contain:

$if\,(TF=1)\ \ f_s(t)=0 \qquad if\,(TF=2)\ \ f_s(t)=5t \qquad if\,(TF=3)\ \ f_s(t)=-t$

$if\,(SF=1)\ \ \frac{dv}{dt}=0 \qquad if\,(SF=2)\ \ \frac{dv}{dt}=(f_s(t)-F_1-F_2v)/m \qquad if\,(SF=3)\ \ \frac{dv}{dt}=(f_s(t)+F_1-F_2v)/m$

The simulated result

The simulated response of the system is shown in Fig.2. This result is done with the modified program with RKM integration subroutines.

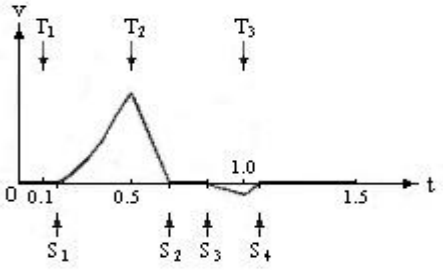

Fig.2 Simulation of the sliding movement system

The 3 time events(T_1,T_2,T_3)and 4 state events (S_1,S_2,S_3, S_4) are encountered in the simulation time interval [0,1.5]of the system. The corresponding [TF,SF] values of the 8 continuous segment states are:[1,1],[2,1],[2,2],[3,2],[3,1],[3,3],[1,3]and [1,1].The changes of the states are respectively caused by passing through zero of ϕ_2 , ϕ_7 , ϕ_3 , ϕ_6 , ϕ_8 , ϕ_4 and ϕ_6 .

The original program is inefficient for the simulation of the sliding movement system. The consumed simulation time approximately increase 6 times. As acrossing the last point of discontinuity failed, the subsequent simulation result errors.

Conclusions

While the sign rule of detecting discontinuities is usually reliable, it causes problem when discontinuity conditions are complicated. Research and practice show that it is able to successfully and effectively deal with this kind of problem by incorporating the system state flag rule of detecting discontinuities and the sequence of linear interpolationsin of locating discontinuities. Required modifications to the original package are done without difficulty. The new integral package can be straightforwardly adapted for dynamics analysis and simulation of engineering systems.

Keywords: logistics engineering; optimization model; hybrid genetic algorithm; closed-loop supply chain logistics network; electronic commerce; goods return; direct shipment.

Abstract. In view of the characteristic of goods return in electronic commerce which some returned goods can be redistributed directly to customers after handling simply, a responsive closed-loop supply chain logistics network with integrating forward and reverse flow is researched. The returning feature of online commodity and economy of scale of return goods at initial collection point are based, and the optimization design model of closed-loop supply chain network aiming at determining the number and location of hybrid centers and initial collection points is presented, and a hybrid genetic algorithm is devised to solve the closed-loop supply chain logistics network problem. The usefulness of the proposed model and algorithm is validated by its application to an illustrative example.

Introduction

There are high rate of goods return under electronic commerce marketing model for some reasons such as damaging commodity, distribution error of goods, merchandise performance doesn't meet customer expectations and so on. The return rate of general goods from online sale is between 20% and 30% [1], but the return rate of some goods such as book, periodical is up to 50% [2]. In view of the characteristic of online sale, most electronic commerce enterprises give refunds policy and bear returning logistics cost, which will become bigger cost resource of electronic commerce enterprises. So improving the effectiveness of handling returning business is an important means of reducing operating cost of e-commerce enterprises. The research work about closed-loop supply chain logistics network has been attracted widespread attention by scholars, and some research fruit are obtained [3-7]. "On time delivery" plays an important role in customer satisfactory and the ability of supply chain to satisfy the customer's expected delivery called "supply chain responsiveness" and helps firms for being the order winner in their goods-markets. According to this point, a number of authors have proposed some models for optimizing the supply chain network considering cost efficiency and network responsiveness simultaneously; meanwhile some authors also consider direct shipment mechanism in supply chain structure. However, to the best of our knowledge there is no research paper discussing closed-loop supply chain considering cost efficiency and network responsiveness simultaneously, meanwhile the direct shipment is allowed, especially in e-commerce environment. In order to fill the void, a closed-loop supply chain logistics network is proposed and a hybrid genetic algorithm with integrating greedy plus algorithm and simplex method is devised to solve this problem.

Problem description and formulation

The considered supply chain network is a single product, multi-stage closed-loop supply chain, which includes plants, hybrid centers with handling forward and reverse logistics, initial collection points and customers, as shown in Fig.1. To research conveniently, some assumptions are made:①there is no capacity limitation in hybrid center for forward logistics; ②all return of goods are shipped to the nearest initial collection point for customer, and the inventory holding period of initial collection point is set to three days; ③the return quantity of customer has positive proportion

to this customer's order quantity, and the induce demand is equal to return quantity; ④all return of goods are divided into direct sale goods by handling simply and indirect sale goods, which the former are distributed equally to forward sale channel in K days, the latter is distributed into plants.

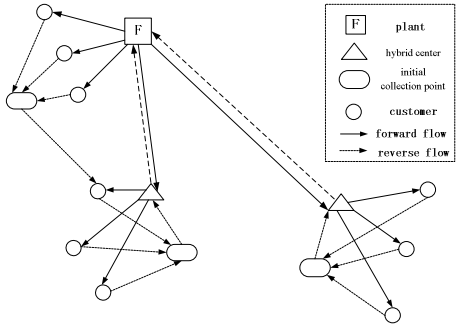

Figure 1. Closed-loop supply chain logistics network

Optimization mode

The following notation is used in the formulation of the considered supply chain network optimization model: F is the set of plant, I is the set of hybrid centers, J is the set initial collection point, L is the set of customers; r_l is demand of customer *i*, θ_l is Return ratio of customer *i*, β is direct utilization ratio of goods returned, Hg_i is Fix cost of hybrid centers *i*, HDe_i is unite operating cost of forward sale at hybrid centers *i*, He_i is unite handling cost for returning at hybrid centers *i*, MHR_i is maximal handling capacity of hybrid centers *i*, Ig_j is annual rent of initial collection point *j*, Ig_j is annual rent of initial collection point *j*, ω is annual working day, P is unite product cost of plants, a, b, c is unite transportation cost from plant to hybrid center, from plant to customer and from hybrid center to customer respectively, h is unite holding cost of initial collection point, v is delivery speed, t_l is maximum delivery tolerance time, d_{ij} is distance from point *i* to point *j*, $d_\max$ is Maximum delivery tolerance distance, f is unite transportation cost from hybrid center to initial collection point

So the decision variables are set as follows:

X_i: if a hybrid center is opened at location i, X_i is set to 1; otherwise 0.

Y_j: if a initial collection point is opened at location j, Y_j is set to 1; otherwise 0.

V_{il}: if customer l is serviced by hybrid center or plant i, V_{il} is set to 1; otherwise 0.

W_{jl}: if customer l is serviced by initial collection point j ,is set to 1; otherwise 0.

G_{ij}: quantity of product shipped from point i to point j.

In terms of the above notation, the considered closed-loop supply chain network optimization model can be formulated as follows.

$$\min Z = \sum_{i\in I} Hg_i \cdot X_i + \sum_{i\in I} G_{0i} \cdot \omega \cdot (P + d_{0i} \cdot a) + \sum_{l\in L} V_{0l} \cdot r_l \cdot (1+\theta_l) \cdot \omega \cdot (d_{0l} \cdot b + P) + \sum_{i\in I}\sum_{l\in L} V_{0l} \cdot r_l \cdot (1+\theta_l) \cdot \omega \cdot (HDe_i + d_{ij} \cdot c)$$

$$\sum_{i\in I}\sum_{j\in J} X_i \cdot G_{ji} \cdot \frac{\omega}{K} \cdot (f \cdot d_{ij} + He_i) + Ig_j \cdot \sum_{j\in J} Y_j + 2h \cdot \omega \cdot \sum_{j\in J}\sum_{l\in L} r_l \cdot \theta_l \cdot W_{jl} \cdot \frac{K+1}{2} + \omega \cdot \sum_{i\in I}\sum_{j\in J} \frac{G_{ji}}{K} \cdot (1-\beta) \cdot d_{0i} \cdot a \quad (1)$$

s.t.

$$\sum_{i\in I\cup F} V_{il} = 1 \quad \forall l \in L \quad (2)$$

$$\sum_{j\in J} W_{jl} = 1 \quad \forall l \in L \quad (3)$$

$$W_{jl} \le Y_j \quad \forall l \in L, j \in J \quad (4)$$

$$\sum_{l\in L} W_{jl} \cdot K \cdot r_l \cdot \theta_l = \sum_{i\in I} G_{ji} \quad \forall j \in J \quad (5)$$

$$G_{oi} + \sum_{j\in J} \frac{G_{ji}}{K} = \sum_{l\in L} V_{il} \cdot r_l \cdot (1+\theta_l) + \sum_{j\in J} \frac{G_{ji}}{K} \cdot (1-\beta) \quad \forall i \in I \quad (6)$$

$$\sum_{l\in L} V_{il} \cdot r_l \cdot (1+\theta_l) \ge \sum_{j\in J} \frac{G_{ji}}{K} \cdot \beta \quad \forall i \in I \quad (7)$$

$$\sum_{j\in J} G_{ji} \le MHR_i \cdot X_i \quad \forall i \in I \quad (8)$$

$$V_{il} \cdot t_l \ge V_{il} \cdot \frac{d_{il}}{v} \quad \forall i \in I \cup F, l \in L \quad (9)$$

$$d_\max \geq W_{jl} \cdot d_{jl} \quad j \in J, l \in L \tag{10}$$

$$X_i, Y_j, V_{il}, W_{jl} \in \{0,1\} \tag{11}$$

$$G_{ji} \geq 0 \quad i \in I, j \in J \tag{12}$$

Optimization objective function: (1) minimizes the annual total cost. Constraint (2) assures that all the demands of customers are satisfied by plant or hybrid center. Constraint (3) (4) ensures returning demand is serviced by a opened initial collection point. Constraint (5) ensures the flow balance at initial collection points. Constraint (6) ensures the flow balance at hybrid centers. Constraint (7) ensures direct utilization quantity of goods returned doesn't exceed the total K days' total demand quantity. Constraint (8) ensures returning quantity of hybrid center doesn't exceed the maximum handling capacity. Constraint (9) (10) ensures the limitation of delivery time and returning distance. Constraint (11) and (12) are related to the binary and non-negativity restrictions on the corresponding decision variables.

Solution method

According to the feature of considered optimization problem, a hybrid genetic algorithm with integrating greedy plus algorithm and simplex method is devised to solve this problem. The step as follows:

Step1 Encoding and initialization. The 0-1 encoding mode is applied, we only encode the location decision variable X_i and Y_j as chromosomes, and the length of chromosomes is $m+n$. The first m genes represent location decision of hybrid centers, and the other n genes represent location decision of initial collection points. the initial chromosomes are produced randomly, and the number is set to pop_size.

Step2 Fitness value calculation. The fitness value includes two parts: objective value and punishment value. There are two sub-algorithms: (1) assignment algorithm: ①firstly, customers are assigned to the nearest plant, opened hybrid center or opened initial collection point. ② the capacity of hybrid center are adjusted to $\min\left\{\sum_{l \in L} V_{il} \cdot r_l \cdot (1+\theta_i) \cdot K/\beta, MHR_i \cdot X_i\right\}$ according to inequality (7) and (8); ③the collection capacity of hybrid centers is calculated. If the capacity is more than the total quantity of goods returned, the assignment procedure end, otherwise the next steps will carry out. ④ a closed location of hybrid center is opened using greedy plus method and shift to ①. The condition of newly added hybrid center shall be demanded is which if this hybrid center is opened, the collection capacity of hybrid centers will be increased after assigning customers to their nearest opened initial collection point and adjusting the capacity of hybrid center. There are two points needed to explain, the punishment value will be made when destroying constraint (9) and (10); (2) simplex method, the transportation problem between hybrid center and initial collection point is solved by simplex method. The Fitness value is calculated by equality function $Fit = 1/(Z+A)$, and the A is punishment value, which is set to the maximal objective value.

Step3 crossover and mutation procedure: the offspring chromosome is obtained by using two-point crossover algorithm and randomly mutation algorithm.

Step4 selection procedure: the offspring chromosomes are ranked by fitness value function, and the new generation is selected by roulette wheel selection and elitism method.

Step5 Stopping criteria: the number of generations reaches a pre-specified upper limit $Popt_\max size$, the calculation procedure ends, otherwise the generation number is increase by one, and shift to step 3 to calculate.

Computational result

An e-commerce company has 30 customers' needs to serviced and the candidate location for hybrid centers and initial collection points are determined before as tab.1, the other parameters are display in tab.2. the parameters of the genetic algorithm are set by a number of experiments: ① $Popt_\max size = 200$; ② $pop_size = 50$; ③ $p_c = 0.9$; ④ $p_m = 0.15$。and customers are uniformly

distributed in a given square region with sixty unites in width. The demand of customers satisfy uniform distribution drawn from [50 350]. According to the computational result, the objective value drops from 118845023 to 74483132, and 37.33% of the initial objective value is optimized, so the usefulness of the proposed model and algorithm is validated.

The location of hybrid centers and initial collection points are determined respectively at hc2, hc3, hc4, hc7, hc8, and cp1, cp2, cp3, cp4, cp6, cp8, cp9, cp10.

TABLE 1. COORDINATE OF LOGISTICS FACILITIES

Coordinate of initial collection points	X	Y	Coordinate of hybrid centers	X	Y
cp1	43.97	49.89	hc1	8.58	30.25

Conclusions

We have studied the optimization problem of responsive closed-loop supply chain logistics network with direct shipment from plant to customer. A optimization model is proposed in order to minimizing the annual operating total cost, and a hybrid genetic algorithm with integrating greedy plus algorithm and simplex method is devised to solve this problem. The usefulness of the proposed model and algorithm is validated by its application to an illustrative example. This research problem can be expanded to optimization problem considering multi-product, multi-period, fuzzy parameter and so on.

Keywords: Crew scheduling; Feasible sets of shifts; Tabu Search

Abstract. Public transit crew scheduling problem is to carry out the operations task with the minimum drivers and operational cost. It is a multi-objective programming problem, which is well-known to be NP-hard. Restrained by the operational constraints and labor agreement, all the feasible sets of shifts were pre-generated in this paper. This work established a penalty function to ensure the validity of the schedule, and a cost function to reduce costs. With the help of Tabu Search, a solution can be found easily. A computational experiment based on the real-world crew scheduling problem in China demonstrates the strength of this method.

Introduction

Crew scheduling problem is one of the most crucial problems for the public transport operation agency. Reasonable crew scheduling can not only reduce operational cost but also affect the operational efficiency.

Since the 1960's, the crew scheduling problem has been discussed by the scholars in western countries. Mitra [1] has proposed a method using Integer Linear Programming to address the crew scheduling problem which is formulated as set covering problem. One of the characteristics of this model is allowing using the shifts which is not been covered while the optimal covering solution is not found. Clement [2] has introduced a Genetic Algorithm to address this problem in which each the chromosome complement represent a feasible crew scheduling solution to genetic operations such as mutation and crossover. Lourenco [3] proposed a Multi-objective formation and calculated by Metaheuristic Algorithms, Tabu Search and Genetic Algorithm. Freling [4] has developed a new method that the crew scheduling problem could be solved by heuristic Branch and Bound Algorithm, which the set covering problem has additional restrictions. Guang-Feng Deng [5] converts the crew scheduling problem into a Traveling Salesman Problem and using Ant colony algorithm to deal with it. De Leone, R [6] developed a new mathematical model just applied to small or medium size problem instances. For large instances, a Greedy Randomized Adaptive Search Procedure (GRASP) is proposed.

Most of the research addressed crew scheduling problem by optimization algorithm and heuristics algorithm when the bus chain set or a spell set is certain, but these methods have to filter the shifts in their scheduling scheme to make sure the time is enough between two spells and the shifts wouldn't break labor rules. However, this paper has pre-generated sets of all the feasible shifts, and solved the scheduling problem by Tabu Search algorithm. In this way, the procedure of filter the valid shifts is passed. In the process of Tabu Search, this paper takes the schedule sets as a shifts chain. Using a state matrix reserve the link between all the shifts, one can observe and evaluate the intermediate results while the algorithm executes further procedures.

Model Formation

On the basis that all shifts must be valid, public transport crew scheduling is to establish a scheduling scheme which must meet: (1) scheduling includes all trips; (2) the number of shifts is minimum; (3) the operational cost is minimum. To achieve the first goal, this paper established a penalty function $g(S)$ to ensure the validity of scheduling. The other goals can be expressed by operational cost function $f(S)$. A weighting factor λ was used to ensure the priority of the first goal.

The objective function can be formulated as follows:

$$F(x) = f(S) + \lambda \times g(S) \tag{1}$$

The smaller $F(x)$ is, the better the solution is.

Operational cost function

It is very important to reduce the number of shifts and operational cost for operating company. These two goals can be combined as a minimization problem.

The model of operational cost is shown in Eq.2 and Eq. 3.

$$f(S)=\sum_{i=1}^{n}\left(h(D_i)+W\right)\times x_i \tag{2}$$

$$h(D_i)=T_1+T_2 \tag{3}$$

Where $x_i=\begin{cases}1 & \text{if shift } i \text{ is selected}\\ 0 & \text{otherwise}\end{cases}$; T_1 represents a crew's working time; T_2 represents a crew's idle time; $h(D_i)$ is a cost function related with shift *i*, which includes crew's working time and idle time; W is a constant much larger than $f(D_i)$, which controls the number of shifts.

Penalty function

Penalty function $g(S)$ ensures the validity of scheduling. The specific rule is that every trips in the final crew scheduling scheme neither repeat nor missing. The validity of scheduling can be shown in Eq. 4.

$$g(S)=e^{\sum_{j=0}^{m} x_j}-1 \tag{4}$$

Where $x_j=\begin{cases}1 & \text{the trip } j \text{ repeat or missing}\\ 0 & \text{otherwise}\end{cases}$ $j=1,...,m$, m represents total numbers of trips.

Eq. 4 shows relation between number of unreasonable trips and value of penalty function is exponential. When $g(S)=0$, scheduling is valid.

The Application of Tabu Search

The application of the Tabu Search in crew scheduling is presented in this section. The procedure of the algorithm is as follows.

Step 1: According to the rules that a feasible shift must obey, our approach calculates the valid sets of shifts and ranks the shifts by departure time of the first trip in ascending order.

Step 2: After generated an initial solution manually, this approach adopted the Tabu Search targeting at minimize the number of shifts and the cost, and got its best solution which is represented as a state array after iterations.

Step 3: Arrange the crew according the state array.

Key factors of Tabu Search

The basic idea of the Tabu Search is to explore the search space of all feasible solutions by a sequence of moves. A move from one solution to another is generally the best available [7].

(1) Pre-generate the feasible sets of shifts

The types of shifts are two: straight duty and spilt duty. Each type of shifts has terms to abide. ①Succession driving time cannot exceed the prescribed time; ②the time from sign on at the depot to sign off for one crew cannot exceed the longest time span; ③each type of shifts cannot exceed the shortest or the longest working hours; ④the dinner time in straight duty must be contained by the specific time range.

Based on these rules that a feasible shift must obey, our approach calculates the valid sets of shifts and ranks the shifts by departure time of the first trip in ascending order.

(2) The construction of the initial solution

The first shift in the sequence of the shifts is selected firstly, and then delete the certain shifts which contains the trips that already been selected. Choose the first shift in the set of remaining shifts and find the other shifts in the same way. Note that the feasible set of shifts is very large and the type of shifts includes straight duty and split duty, so it is possible to find a valid initial solution.

(3) Neighborhood

In the algorithm, crew scheduling (set of some shifts contains exactly all trips) is operated as a shift chain. We can describe links between different shifts with a state matrix R, as shown below.

$$R=\begin{bmatrix} 0 & r_{12} & r_{13} & \cdots & r_{1p-1} & r_{1p} \\ 0 & 0 & r_{23} & \cdots & r_{2p-1} & r_{2p} \\ 0 & 0 & 0 & \cdots & r_{3p-1} & r_{3p} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & 0 & 0 & r_{p-1p} \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}_{p\times p}$$

Where $r_{ij}=\begin{cases}1 & \text{shift } j \text{ is follow with shift } i \\ 0 & \text{otherwise}\end{cases}$; p is the number of feasible shifts; the number of shifts in crew scheduling is $n=\sum_{i=0}^{p}\sum_{j=0}^{p} r_{ij}+1$.

Neighborhood can be divided into three types, replacement, insertion and deletion. Replacement is defined as the procedure which two shifts of the current solution is replaced, as explained below. All feasible shifts are divided into some categories in accordance with the first trip; two random shifts of the current solution are replaced by other shifts in the same categories. It can narrow the scale of neighborhood and improve operation efficiency, as shown in Fig. 1. This is, in state matrix R, the values of r_{12}, r_{24}, r_{45} and r_{57} are changed from 1 to 0, the values of r_{13}, r_{34}, r_{46} and r_{67} are changed from 0 to 1, other values are remain unchanged. The transformation of state matrix represents the trajectory that the current solution moves to its neighborhood. Insertion and deletion are shown in Fig. 2 and Fig. 3.

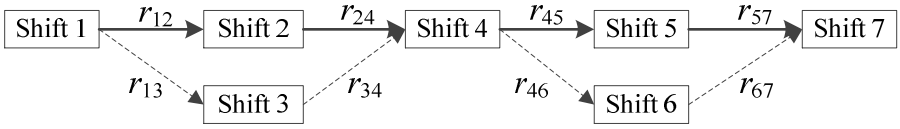

Fig. 1 Replacement

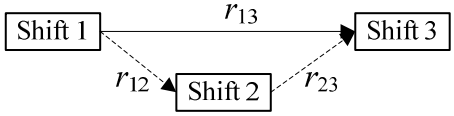

Fig. 2 Insertion

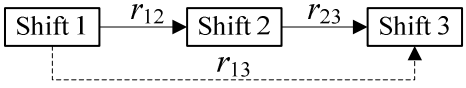

Fig. 3 Deletion

(4) Tabu list and aspiration criterion

Tabu object is defined as the moving of crew scheduling, namely transformation because of a moving. Each moving corresponds to a tabu value. Tabu length refers to how many iteration steps tabu object is not allowed, namely tabu objects are banned in I steps iterative. The tabu value minus 1 during each iteration, and when the value is zero, the object is free from tabu list. Aspiration criterion is defined to ignore the taboo attribute when the value of the current solution surpasses the history optimal value. Aspiration criterion can release a specific solution when all candidate solutions or the one better than the current optimal solution candidate solution is banned, so as to realize the global optimization search.

(5) Candidate and evaluation function

When neighborhood is huge, selecting a part of good candidate in the space of neighborhood can improve the efficiency of operation. The scale of the candidate can be set according to the needs and experiences, so as to improve the efficiency of search. The value of solution is calculated

through the evaluation function. In this paper, evaluation function is the optimization objective (Eq. 1) which is a simple, intuitive method, and the smaller the target value is, the better the solution is.

(6) Termination criterion

Termination criterion is defined to stops searching process under certain conditions. In actual operation, the following approximate termination criterions are often used: ①iteration steps have reached a determined number; ②frequency of a certain tabu object surpass a given value; ③the current optimal value does not change in a certain number of steps, the calculation terminates.

The procedure to the Algorithm

Tabu Search targeting at minimize the number of shifts and the total cost, the procedure to the algorithm is designed as follows:

Step 1: Initialized all the parameters and set the loop is zero, the tabu list is null.

Step 2: The initial solution is constructed, set the initial solution as current solution and its value is current optimal solution value f^*;

Step 3: Set $i := i+1$;

Step 4: If the termination condition is satisfied, transfer to step 10; otherwise, continue;

Step 5: Search and choose the candidate from the neighborhoods of the current solution;

Step 6: Rank the value of candidate in ascending order, set j=0, and set the jth candidate solution value is f_j;

Step 7: Set $j := j+1$;

Step 8: If f_j is less than f^*, set $f^* := f_j$, and the jth candidate solution as the current solution, go to Step 3; otherwise, continue;

Step 9: If the jth candidate solution violates the tabu rule, transfer to Step 7; otherwise, set the jth candidate solution as the current solution, and transfer to Step 3;

Step 10: Termination.

Example

In this section, Line 26 (from Erlizhuang to Xibianmen) and Line 635 (from Erlizhuang to Kangjiagou) in Beijing are taken as examples. The origin data includes trips, departure time, travel time, arrival time, etc. The travel time of Line 26 is 78min, and Line 635 is 80min. According to Difference Sequence Method, the number of departures for Line 26 and Line 635 is shown in Table 1 and Table 2.

Table 1 Number of departures for Line 26

Time / Direction	5:30-7:00	7:00-8:00	8:00-11:00	11:00-15:00	15:00-17:00	17:00-22:00
Up	10	12	30	33	20	42
Down	13	13	27	33	22	39
The number of departures per hour	15.3	25	19	16.5	21	16.2

Table 2 Number of departures for Line 635

Time / Direction	5:30-8:00	8:00-15:00	15:00-17:00	17:00-18:00	18:00-19:00	19:00-22:00
Up	26	59	19	11	10	17
Down	28	57	19	13	7	18
The number of departures per hour	21.6	16.5	19	24	17	20

This sample covers 578 trips, and the total operating time is 761 hours. All feasible shifts are 9841 so that it can' be solved by enumeration method. This work was coded in C#. All the program were run on the Pentium(R) Dual-Core E5800 CPU 3.20 GHz with 2GB RAM PC and Windows XP operating system.

Parameters about Tabu Search are set as follows: λ=1000, W=100, the scale of candidates is 100, the tabu length is 10, and if the current optimal value does not change in 50 steps, the calculation terminates.

Table 3 shows the comparison between the origin scheme and the new scheme by Tabu Search.

Table 3 Comparison

Items		Origin	New	Difference	Percentage
Line26	Total shifts	52	50	2	3.80%
	Total idle time	83.2h	68.9h	14.3h	17.18%
	Total operating time	382.2h	382.2h	0	0.00%
Line635	Total shifts	52	49	3	5.70%
	Total idle time	88.1h	66.8h	21.3h	24.18%
	Total operating time	378.7h	378.7h	0	0.00%

Table 3 indicates that the calculation results in the total number of shifts and total idle time are less than the original scheme, respectively. In summary, the crew schedule by Tabu Search is obviously better than the original one. The calculation result of this sample shows that the design of Tabu Search algorithm in this paper can solve the crew scheduling problem effectively, and can get less number of shifts and lower operation cost solution with good optimization performance.

Conclusions

Crew scheduling problem is one of the crucial issues for the public transit agency. Reasonable schedule can not only reduce operational cost, but also affect the operational efficiency. Pre-generate a set of feasible shifts and solve the problem by Tabu Search can skip the procedure of filter the valid shifts and achieve the schedule fast. Consequently, this method has a good effect on the reduction of the number of total shifts and the operation cost when solving the large-scale crew scheduling problem.

Keywords: Harmony search algorithm; mutation operation; modified harmony search; convergence

Abstract. Harmony search algorithm is a new meta-heuristic optimization method imitating the music improvisation process where musicians improvise their instruments' pitches searching for a perfect state of harmony. To enable the harmony search algorithm to transcend its limited capability of local optimum, a modified harmony search algorithm is proposed in this paper. In the modified harmony search algorithm, the mutation operation of differential evolution algorithm is introduced into MHS algorithm, which improves its convergence. Several standard benchmark optimization functions are to be test and compare the performance of the MHS. The results revealed the superiority of the proposed method to the HS and recently developed variants.

Introduction

Numerical optimization has an important position in agriculture, industry and finance economic. It is always as a standard for the optimization performance of algorithm. Traced back a long time ago, we usually use traditional methods such as liner programming, dynamic programming, conjugate gradient method, quasi-Newton method to solve unconstrained numerical optimization problems. However, with the increasing number of dimension, the numerical optimization problem become more and more complicated, which is easily lead the traditional methods trapped into dimension curse. However, the meta-heuristic algorithms have outperformed conventional numerical methods on providing better solutions for some difficult real world optimization problems.Researchers have to research meta-heuristic algorithms, such as the genetic algorithm, ant colony algorithm, particle swarm algorithm and the differential evolution algorithm; currently these meta-heuristic algorithms have been successfully applied to various complex optimization problems [1-4]. The meta-heuristic algorithms present several advantages with respect to the traditional optimization algorithms such as the meta-heuristic algorithms able to perform global search as well as local search and efficiently handling discrete variables.

Recently, Geem et al proposed a new meta-heuristic algorithm and named harmony search algorithm (HS) [5]. Harmony search algorithm is conceptualized using the musical improvisation process of searching for a perfect state of harmony. Harmony search algorithm is good at identifying the high performance regions of the solution space at a reasonable time. It has been successfully applied to many engineering optimization problems [6-8]. Nevertheless, it also suffers from a serious problem as other meta-heuristics does. It easily gets into trouble in performing local search for numerical applications. Thus, some improved variants were developed for enhancing algorithm optimizing performance, such as: improved harmony search (IHS) algorithm [9], self-adaptive global-best harmony search (SGHS) algorithm [10], Global-best harmony search (GHS) algorithm [11], and novel global harmony search (NGHS) algorithm [12].

Modified Harmony Search(MHS) Algorithm

Inspired by the concept of differential mutation as proposed in Differential Evolution (DE) [13], a modified HS is proposed in this paper. In DE algorithm, three individuals x_{r1}, x_{r2} and x_{r3} are pseudo-

randomly extracted from the population. The following are different mutation strategies frequently used in the literature:

DE/rand/1 $v_i = x_{r0} + F \times rand \times (x_{r1} - x_{r2})$ (1)

DE/best/1 $v_i = x_{best} + F \times rand \times (x_{r2} - x_{r3})$ (2)

DE/rand/ $v_i = x_{r0} + F \times rand \times (x_{r1} - x_{r2}) + F \times rand \times (x_{r3} - x_{r4})$ (3)

DE/best/2 $v_i = x_{best} + F \times rand \times (x_{r1} - x_{r2}) + F \times rand \times (x_{r3} - x_{r4})$ (4)

DE/current-to-best/1 $v_i = x_{r0} + F \times rand \times (x_{best} - x_{r1}) + F \times rand \times (x_{r2} - x_{r3})$ (5)

Where the indices r0, r1, r2, r3 and r4 are distinct integers uniformly chosen from the set {1,2,...,NP}; x_{best} is the best vector in the current iteration; F represents the scaling factor; rand belongs to a uniform distribution in the ranges [0,1].

The classic DE/rand/1 is known to be robust but less efficient in terms of convergence rate. The other best variant is DE/best/1, which utilizes the information of the best solution in current population. The mutation operation DE/best/1 can fast speed up the convergence rate and improve the convergence performance.

In view of the above consideration, and combine the search mechanism of harmony search algorithm, we introduce a new greedy mutation strategy and modify the pitch adjustment step of the HS. The new greedy mutation strategy as follow:

$$x_j^{new} = w \times x_j^{best} + F \times rand \times (x_j^{r2} - x_j^{r3}) - (x_j^{r2} - x_j^{r3}) \quad (6)$$

$$w = w_{\min} + \frac{K-k}{K} \times (w_{\max} - w_{\min}) \quad (7)$$

Where $w_{\max}$ and $w_{\min}$ are the upper and lower weight value, respectively. K is the maximum number of iterations, and k is the current number of iterations; rand belongs to a uniform distribution in the ranges [0,1]; the indices r_2 and r_3 are distinct integers uniformly chosen from the set（1，2，…，HMS） and （1，2，…，N）, respectively; F is the scaling factor that is a positive control parameter for scaling the difference decision variable; x_j^{new} represents the jth decision variable of the new harmony vector at the current iteration k, and x_j^{r2} represents the jth decision variable of the r_2 harmony vector in the current harmony memory, x_j^{r3} the same as x_j^{r2} .The MHS algorithm has exactly the same steps as the HS algorithm with the exception that Step 3 is modified as follow:

for j =1 to N do

if rand()≤HMCR then

$x_j^{new} = x_j^{r}, (r \in (1,2,\cdots,HMS))$ % memory consideration

if rand()≤PAR then

$x_j^{new} = w \times x_j^{best} + F \times rand \times (x_j^{r2} - x_j^{r3}) - (x_j^{r2} - x_j^{r3})$ %pitch adjustment

end

else $x_j^{new} = x_{jL} + rand \times (x_{jU} - x_{jL})$ %random selection end end

Experimental Results and Analysis

Ten test functions are considered to extensively investigate the performance of the MHS algorithm, and they are presented as follows:

f_1 Sphere function, defined as $\min f_1 = \sum_{i=1}^{N} x_i^2$, f_2 Rosenbrock function, defined as $\min f_2 = \sum_{i=1}^{N-1} (100(x_{i+1} - x_i^2)^2 + (x_i - 1)^2)$, f_3 Rastrigrin function, defined as $\min f_3 = \sum_{i=1}^{N} (x_i^2 - 10\cos(2\pi x_i) + 10)$, f_4 Griewank function, defined as $\min f_4 = \frac{1}{4000}\sum_{i=1}^{N} x_i^2 - \prod_{i=1}^{N} \cos(\frac{x_i}{\sqrt{i}}) + 1$, f_5 Ackley's function, defined

as $\min f_5 = 20 + e - 20\exp(-0.2\sqrt{\frac{\sum_{i=1}^{N} x_i^2}{N}}) - \exp(\frac{\sum_{i=1}^{N}\cos(2\pi x_i)}{N})$, f_6 Schwefel's problem 2.22, defined as $\min f_6 = \sum_{i=1}^{N}|x_i| + \prod_{i=1}^{N}|x_i|$, f_7 Zakharov function, defined as $\min f_7 = \sum_{i=1}^{N} x_i^2 + \left(\sum_{i=1}^{N} 0.5ix_i^2\right)^2 + \left(\sum_{i=1}^{N} 0.5ix_i^2\right)^4$, f_8 Rotated hyper-ellipsoid function, defined as $\min f_8 = \sum_{i=1}^{N}(\sum_{j=1}^{i} x_j)^2$, f_9 Shifted Rotated high conditioned Elliptic function, define as $\min f_9 = \sum_{i=1}^{N}(10^6)^{\frac{i-1}{N-1}} z_i^2 - 450$, f_{10} Shifted Schwefel's problem 1.2 with noise, defined as $\min f_{10} = \sum_{i=1}^{N}(\sum_{j=1}^{i} z_j)^2(1 + 0.4*|N(0,1)|) - 450$

In the experiments, the settings of compared HS algorithms are show in table 1. The results reported in this section are best, worst, mean and standard deviation (SD) over 30 independent simulations. For each simulation was allowed to run 50000 evaluations of the objective function the numerical results using four harmony search algorithm are reported in Table 2.

Conclusions

In the MHS algorithm, a new greedy mutation strategy was introduced and modified the pitch adjustment operation, which makes it easier to explore a better solution and balance the local search and global search well. What's more, the MHS algorithm utilize the best harmony vector to generate a new harmony, which speed up the algorithm search rate and improve the solution accuracy. Besides, Combine with the search mechanism of the original harmony search algorithm, the MHS algorithm enhances stability. Based on several high dimension standards benchmark optimization problems carried out to be tested, the results obtained using the MHS algorithm may yield better solutions than those obtained using HS, IHS and GHS algorithm, and demonstrate the effectiveness and robustness of the proposed algorithm.

Keywords: modified harmony search; self-learning strategy; convergence; stability

Abstract. This paper presents a modified harmony search (MHS) algorithm for solving numerical optimization problems. MHS employs a novel self-learning strategy for generating new solution vectors that enhances accuracy and convergence rate of harmony search (HS) algorithm. In the proposed MHS algorithm, the harmony memory consideration rate (HMCR) is dynamically adapted to the changing of objective function value in the current harmony memory. The other two key parameters PAR and bw adjust dynamically with generation number. Based on a large number of experiments, MHS has demonstrated stronger convergence and stability than original harmony search (HS) algorithm and its two improved algorithms (IHS and GHS).

Introduction

Recently, a novel metaheuristic optimization algorithm- harmony search (HS) was developed by Geem et al in 2001[1], which are conceptualized using the musical improvisation process of searching for a perfect state of harmony. Owing to its own potential and shortage, there has been an increasing interest in the study of improved HS algorithm during the recent few years. These improved harmony search algorithms as following: improved harmony search (IHS) algorithm [2], self- adaptive harmony search algorithm [3], parameter- setting-free harmony search algorithm [4] global-best harmony search (GHS) algorithm [5] self-adaptive global best harmony search algorithm (SGHS) [6], novel global harmony search (NGHS) algorithm [7]. These improved harmony search algorithms are good at identifying the high performance regions of the solution space at a reasonable time, but get into trouble in performing local search for numerical applications. Although several variants and an increasing number of applications have appeared, one of its main difficulties is how to select suitable parameter values. HS algorithm's performance, however, is still quite dependent on the setting of control parameters such as pitch adjusting rate (PAR) and distance bandwidth (bw) probability according to trial-and-error method. Although there are many researchers contribute to how to design a skill to choose the suitable parameter settings to ensure the success of the algorithm, the affections between the parameter setting and the optimization performance is still complicated and not completely understood. How to efficiently adaptively setting suitable parameter values is still a main work to improve HS algorithm optimization performance.

A Modified Harmony Search (MHS) Algorithm

Inspired by the differential evolution algorithm, a self-learning harmony search algorithm is presented in this section. MHS employs a novel self-learning strategy (or differential learning approach) and a dynamically adaptive parameter tuning methods. The details of the MHS algorithm are presented below.

Self-Learning Strategy

A self-learning strategy is proposed in the MHS algorithm, and it expressed as follow:

$$x_i^{new}(k) = \frac{K-k}{K} \times x^{r_1}{}_{r_2}(k) + F \times rand_i \times (x^{r_1}{}_i(k) - x^{r_1}{}_{r_2}(k)) \tag{1}$$

where K is the maximum number of iterations, and k is the current number of iterations; randi belongs to a uniform distribution in the ranges [0,1]; the indices r_1 and r_2 are distinct integers uniformly chosen from the set（1，2，…，HMS） and （1，2，…，N）,respectively; F is the scaling factor that is a positive control parameter for scaling the difference decision variable; $x_i^{new}(k)$ represents the ith decision variable of the new harmony vector at the current iteration k, and $x^{r_1}{}_i(k)$ represents the ith decision variable of the r1 harmony vector in the current harmony memory. ($x^{r_1}{}_{r_2}(k)$ and $x^{r_1}{}_{r_2}(k)$ have the same meaning as $x^{r_1}{}_i(k)$).the former part ($\frac{K-k}{K}\times x^{r_1}{}_{r_2}(k)$) play a key role in the early iterations, In this case, any decision variable of the new harmony vector keeps the decision variables from the HM with a large probability, so the new harmony vector is more like a conservative one that conserve the good part by learn from themselves in the early iterations. With the increase of iteration k, The effect of the former part decreases , but the latter part（$F\times rand_i\times(x^{r_1}{}_i(k)-x^{r_1}{}_{r_2}(k))$） become important. The latter part is just like differential evolution mutation strategy; this part is called neighborhood learning. In the late iterations, the weight ($(K-k)/K$) becomes very small, and the latter part has primarily effects on the decision variable of the new harmony vector by random decision variable differential. In this case, any decision variable of the new harmony vector to mutate to a new one from the HM, which provides a promising and alternative search direction for each harmony vector.

The Key Parameter Setting For MHS

HMCR is the probability of choose one value from the historic values stored in the HM. Here the HMCR adaptively adjusted according to the objective function value in the current harmony memory, and it is stated as follows:

$$HMCR_k=\begin{cases}1, & if \quad \dfrac{f^{k-1}{}_{aver}-f^{k-1}{}_{\min}}{f^{k-1}{}_{\max}-f^{k-1}{}_{aver}}>1\\ \dfrac{f^{k-1}{}_{aver}-f^{k-1}{}_{\min}}{f^{k-1}{}_{\max}-f^{k-1}{}_{aver}}, & otherwise\end{cases} \tag{2}$$

Where $f^{k-1}{}_{\min}$ represents the minimal objective function value of all harmony solution vector at iteration k-1, $f^{k-1}{}_{aver}$ represents the average objective function value of all harmony solution vector at iteration k-1, $f^{k-1}{}_{\max}$ represents the maximal objective function value of all harmony solution vector at iteration k-1.A closer look at adaptive harmony memory consideration rate HMCRk reveals that each iteration solution has its own unique HMCR according to the ratio of ($f^{k-1}{}_{aver}-f^{k-1}{}_{\min}$) and ($f^{k-1}{}_{\max}-f^{k-1}{}_{\min}$). If the objective function value of the solution is close to $f^{k-1}{}_{\min}$, $HMCR_k$ tends to be a small value, which is beneficial to the global search of the MHS, otherwise, HMCRk tends to be a large value, which is beneficial to the local search of the SSHS. In short, the adaptive HMCR can balance the local search and global search well.

PAR and bw change dynamically with generation number as expressed as follow:

$$PAR(k)=PAR_{\min}+\frac{(PAR_{\max}-PAR_{\min})}{K}\times k \tag{3}$$

$$\mathrm{bw}(k)=\mathrm{bw}_{\max}\exp(c\cdot k),\ c=\frac{\ln\left(\dfrac{\mathrm{bw}_{\min}}{\mathrm{bw}_{\max}}\right)}{K} \tag{4}$$

Where K is the maximum number of iterations, and k is the current number of iterations; PARmin and PARmax are the minimum adjusting rate and the maximum adjusting rate respectively; bwmin and bwmax are the minimum bandwidth and the maximum bandwidth respectively.

Computational Procedure of the MHS

The Computational procedure of the MHS algorithm can be summarized as follows:

(1) Begin

(2) Set harmony memory size HMS, adjusting rate PAR, distance bandwidth bw, the number of decision variables N and maximal iteration number K.

(3)Initialize harmony memory HM, upper bands of variables $x_U = (x_{1U}, x_{2U}, \ldots, x_{NU})$ and lower bands $x_L = (x_{1L}, x_{2L}, \ldots, x_{NL})$. Harmony memory (HM) is generated from a uniform distribution in the ranges $[x_{jL}, x_{jU}], (j = 1, 2, \cdots, N)$

(4) Improvise a new harmony from the HM

Calculate the objective function values of all harmony solution vectors. Calculate $f^{k-1}{}_{aver} = \frac{1}{HMS}\sum_{i=1}^{HMS} f^{k-1}{}_i$ and find out $f^{k-1}{}_{\max}$, $f^{k-1}{}_{\min}$.

Calculate HMCRK and then conduct improvisation processes, include memory consideration, pitch adjustment and random selection. In the memory consideration, self-learning strategy applied to this part.

(5) Update harmony memory

(6) Check the stopping criterion

Experimental Results and Analysis

To test the performance of the proposed MHS algorithm, an extensive experimental evaluation and comparison with the HS, IHS and GHS algorithms are provided based on a set of 6 global optimization problems as follows:

f_1 Sphere function, defined as $\min f_1 = \sum_{i=1}^{N} x_i^2 \quad -100 \le x_i \le 100 \ (i = 1, 2, ..., N)$

Where global optimum $x^* = (0, 0, ..., 0)$ and $f(x^*) = 0$

f_2 Rastrigrin function, defined as $\min f_2 = \sum_{i=1}^{N} (x_i^2 - 10\cos(2\pi x_i) + 10)$ Where global optimum $x^* = (0, 0, ..., 0)$ and $f(x^*) = 0$ for $-10 \le x_i \le 10 \ (i = 1, 2, ..., N)$.

f_3 Griewank function, defined as

$\min f_3 = \frac{1}{4000}\sum_{i=1}^{N} x_i^2 - \prod_{i=1}^{N} \cos(\frac{x_i}{\sqrt{i}}) + 1$ Where global optimum $x^* = (0, 0, ..., 0)$ and $f(x^*) = 0$ for $-600 \le x_i \le 600 \ (i = 1, 2, ..., N)$

f_4 Ackley's function, defined as $\min f_4 = 20 + e - 20\exp(-0.2\sqrt{\frac{\sum_{i=1}^{N} x_i^2}{N}}) - \exp(\frac{\sum_{i=1}^{N} \cos(2\pi x_i)}{N})$ Where global optimum $x^* = (0, 0, ..., 0)$ and $f(x^*) = 0$ for $-32 \le x_i \le 32 \ (i = 1, 2, ..., N)$.

f_5 Schwefel's problem 2.22, defined as $\min f_5 = \sum_{i=1}^{N} |x_i| + \prod_{i=1}^{N} |x_i|$ Where global optimum $x^* = (0, 0, ..., 0)$ and $f(x^*) = 0$ for $-100 \le x_i \le 100 \ (i = 1, 2, ..., N)$.

f_6 Rotated hyper-ellipsoid function, defined as $\min f_6 = \sum_{i=1}^{N} (\sum_{j=1}^{i} x_j)^2$ Where global optimum $x^* = (0, 0, ..., 0)$ and $f(x^*) = 0$ for $-100 \le x_i \le 100 \ (i = 1, 2, ..., N)$

For each function, 30 independent experiments are carried out in each case, and the numerical results using four harmony search algorithm are reported in Table 1, The "SD" represents standard deviation. The maximum number of iterations is set to 10000 for 6 functions. It can be see from Table 2, that the MHS algorithm is the best algorithm since it generates all 6 significantly better results than the HS, IHS and GHS algorithms for the 6 test functions. MHS performs better than the other three approaches in terms of solution accuracy on the utilized 6 test functions.

Conclusions

This paper proposes a new simple but effective and efficient MHS algorithm for unconstrained optimization problems with continuous decision variables. Unlike the HS algorithm, the MHS designs a novel self-learning strategy, which makes it easier to explore a better solution and to converge. In addition, the harmony memory consideration rate (HMCR) is dynamically adapted to the changing of objective function value in the current harmony memory, which it can balance, the local search and global search well. Based on a large number of experiments, the results obtained using the MHS algorithm may yield better solutions than those obtained using HS, IHS and NGHS algorithm, and demonstrate the effectiveness and robustness of the proposed algorithm. In short, the MHS algorithm is a promising optimization algorithm, and it has high exploration capability of solution space throughout the whole iteration.

Keywords: MDE; position updating; disturbance; convergence; dynamic

Abstract. In this paper, a modified differential evolution algorithm (MDE) developed to solve unconstrained numerical optimization problems. The MDE algorithm employed random position updating and disturbance operation to replaces the traditional mutation operation. The former can rapidly enhance the convergence of the MDE, and the latter can prevent the MDE from being trapped into the local optimum effectively. Besides, we dynamic adjust the crossover rate (CR), which is aimed at further improving algorithm performance. Based on several benchmark experiment simulations, the MDE has demonstrated stronger convergence and stability than original differential (DE) algorithm and its two improved algorithms (JADE and SaDE) that reported in recent literature.

Introduction

In 1995, a new floating point encoded an evolutionary algorithm for global optimization; called Differential Evolution (DE) was proposed. Differential Evolution, inspired by the natural evolution of species, has been successfully applied to solve numerous optimization problems in diverse fields. However, when implementing the DE, users not only need to determine the appropriate encoding schemes and evolutionary operators, but also need to choose the suitable parameter settings to ensure the success of the algorithm, which may lead to demanding computational costs due to the time-consuming trial-and-error parameter and operator tuning process. To overcome such inconvenience, researchers have actively investigated the adaptation of parameters and operators in DE. Literature [1] divided the parameter adaptation techniques into three categories: deterministic, adaptive, and self-adaptive control rules. Deterministic rules modify the parameters according to certain predetermined rationales without utilizing any feedback from the search process. Adaptive rules incorporate some form of the feedback from the search procedure to guide the parameter adaptation. Self-adaptive rules directly encode parameters into the individuals and evolve them together with the encoded solutions. Parameter values involved in individuals with better fitness values will survive, which fully utilize the feedback from the search process. Generally speaking, self-adaptive rules can also refer to those rules that mainly utilize the feedback from the search process such as fitness values to guide the updating of parameters. Differential Evolution uses a special kind of differential operator, and recently, it has been applied in different fields of engineering and science [2-4].

The performance of the conventional DE algorithm highly depends on the chosen trial vector generation strategy and associated parameter values used. Inappropriate choice of strategies and parameters may lead to premature convergence or stagnation, which have been extensively demonstrated in [5] and [6]. In this paper, we propose a modified differential evolution (MDE) algorithm to avoid the expensive computational costs spent on searching for the most appropriate trial vector generation strategy, as well as its associated parameter values by a trial-and-error procedure. Instead, both strategies and their associated parameters are adjusted adaptively to prevent algorithm trapped into local optima.

The Modified Differential Evolution (MDE) Algorithm

The original particle swarm optimization algorithm works as follow:

$$v_i = v_i + c1 \times rand \times (x_l - x_i) + c1 \times rand \times (x_g - x_i)$$

$$x_{i+1} = x_i + v_i$$

Where v_i and x_i represent the speed and position of individual in current iteration, respectively; x_l and x_g are the personal best position and the global best in the current iteration, respectively. Original particle swarm optimization algorithm developed to be a classic particle swarm optimization (PSO) algorithm, which different from original PSO only add inertia weight W for the speed updating. The impact of inertia weight W is to keep the individual advantage in the search process. Inspired by the classic PSO algorithm, in this section, modified differential evolution is proposed. The MDE and the DE are different in two aspects as follow:

(1)Pitch adjustment instead of traditional mutation operation, which is works as follow:

```
if rand<Mr
%random position updating
    if rand>0.5
        v_{i,k} = x_{best,k} + rand_1 · (x_{r1,k} − x_{r2,k})
    elseif rand≤0.5
        v_{i,k} = x_{r0,k} - rand_2 · (x_{r1,k} − x_{r2,k})
    endif
else
    v_{i,k} = rand · (x_max − x_min) + x_min %disturbance operation
end
```

Here, the indices r0, r1 and r2 are distinct integers uniformly chosen from the set {1,2,...,NP}; x_{best} is the best vector in the current iteration k; rand, rand1 and rand2 belongs to a uniform distribution in the ranges [0,1]; Mr represent the position updating rate. In general, Mr is larger than 0.9.

(2) To well balance the exploration and exploitation of the proposed MDE algorithm, the CR value increases dynamically with increasing generations (k) as follows:

$$CR_k = CR_{\min} \exp(c \cdot k),\ c = \frac{\ln\left(\frac{CR_{\max}}{CR_{\min}}\right)}{K} \quad (1)$$

Where K is the maximum number of iterations, and k is the current number of iterations; wmin and wmax are the minimum inertia weight and the maximum inertia weight, respectively; CRmin and CRmax are the minimum crossover rate and the maximum crossover rate, respectively.

Experimental Results and Analysis

To test the performance of the proposed MDE algorithm, an extensive experimental evaluation and comparison with the DE/rand/1, DE/best/1,PSO, JADE and SaDE algorithms are provided based on a set of four global optimization problems as follows:

f_1 Sphere function, defined as $\min f_1 = \sum_{i=1}^{N} x_i^2$

Where global optimum $x^* = (0,0,...,0)$ and $f(x^*) = 0$ for $-100 \le x_i \le 100\ (i = 1,2,...,N)$.

f_2 Rastrigrin function, defined as $\min f_2 = \sum_{i=1}^{N} (x_i^2 - 10\cos(2\pi x_i) + 10)$

Where global optimum $x^* = (0,0,...,0)$ and $f(x^*) = 0$ for $-10 \le x_i \le 10\ (i = 1,2,...,N)$.

f_3 Griewank function, defined as

$$\min f_3 = \frac{1}{4000} \sum_{i=1}^{N} x_i^2 - \prod_{i=1}^{N} \cos\left(\frac{x_i}{\sqrt{i}}\right) + 1$$

Where global optimum $x^* = (0,0,...,0)$ and $f(x^*) = 0$ for $-600 \le x_i \le 600\ (i = 1,2,...,N)$.

f_4 Ackley's function, defined as

$$\min f_4 = 20 + e - 20\exp(-0.2\sqrt{\frac{\sum_{i=1}^{N} x_i^2}{N}}) - \exp(\frac{\sum_{i=1}^{N}\cos(2\pi x_i)}{N})$$ Where global optimum $x^* = (0,0,...,0)$ and $f(x^*) = 0$ for $-32 \le x_i \le 32\ (i = 1,2,...,N)$.

f_5 Schwefel's problem 2.2, defined as

$$\min f_5 = \sum_{i=1}^{N} |x_i| + \prod_{i=1}^{N} |x_i|$$

Where global optimum $x^* = (0,0,...,0)$ and $f(x^*) = 0$ for $-100 \le x_i \le 100\ (i = 1,2,...,N)$.

MDE is compared with two classic differential evolution algorithm DE/rand/1 and DE/best/1, PSO, as well as two recent adaptive DE algorithms JADE and SaDE, and the classic DE/rand/1. For fair comparison, we set the parameters of MDE to be fixed, wmin=0.05, wmax=0.9 and CRmin=0.1, CRmax=0.9 in all simulations. We follow the parameter settings in the original paper of JADE [1] and SaDE [7], except that the parameters of DE/rand/1 are set to be F=0.5 and CR=0.9. The results reported in this section are best, worst, mean and standard deviation (SD) over 30 independent simulations. For each simulation, all the procedure to be run in computer Inter(R) Pentium(R) 4, CPU 2.93GHz, and the numerical results using four differential evolution algorithm are report in Table 1.

Conclusions

This paper proposes a new simple but effective and efficient MDE algorithm for unconstrained optimization problems with continuous decision variables. In the MDE algorithm, new random position updating strategy and disturbance operation were introduced and dynamically adjusted the parameter value of the algorithm, which makes it easier to explore a better solution and balance the local search and global search well. Based on several standards benchmark optimization problems carried out to be tested, the results obtained using the MDE algorithm may yield better solutions than those obtained using DE/rand/1, DE/best/1, PSO, JADE and SaDE algorithm, and demonstrate the effectiveness and robustness of the proposed algorithm. In short, the MDE algorithm is a promising optimization algorithm, and it has high exploration capability of solution space throughout the whole iteration.

Keywords: people counting; optical flow algorithm; moving feature

Abstract. In order to improve the accuracy of people counting in video surveillance, the method for people counting based on the moving feature of the mass is proposed. We obtain the orientation and energy density of mass through the optical flow algorithm, and get the information about the size of mass to design the feature of mass. The people counting model is obtained by training a support vector machine (SVM) classifier with the moving feature and shape feature of mass. The experimental results confirm that our approach improves the accuracy of people counting.

Introduction

People counting based on video is an important application in real life. In recent years, many approaches are proposed based on video-based techniques. The method [1] utilizes the foreground segmentation by Gaussian Mixture Model to count people, and the method [2] analyzes the moving features and distribution of directions of people counting.

Above these methods neglect the information about the moving mass. Therefore, we introduce sizes of moving foreground masses and the histograms of the directions about optical flow of masses by quantizing to form the feature of mass. By training a support vector machine (SVM) classifier with the input of the feature of mass, the people counting model is obtained. Our main contribution is proposing a novel feature of mass which can characterize the intrinsic energy and size properties accurately.

Overview of Our Algorithm

The framework of the method consists of training section and detecting section. Firstly, we get the foreground moving mass in the video of cameras by using Gaussian Mixture Model; Secondly, we calculate the direction of the mass using the optical flow method at first, and then segment the peoples of different directions in the same mass according to the direction information, and complete the mass segmentation; Finally, we train the SVM classifier to complete people counting.

Get foreground mass region. First of all, Gaussian Mixture Model is used for getting the moving foreground mass by using the definition of K (the value range of K is 3-5) Gaussian models for each pixel firstly. Suppose the set $\{x_t\}_{t=1}^{L}$ is a set of pixels in a period of time, where L is the total frame number, x_t is the pixel value at time t, its probability is:

$$P\{x_t\} = \sum_{j=1}^{K} \omega_{j,t} \eta\left(x_t, \mu_{j,t}, \sigma_{j,t}\right) \tag{1}$$

$$\eta\left(x_t,\mu_{j,t},\sigma_{j,t}\right)=e^{\frac{1}{2\sigma_{j,t}^2}\left(x_t-\mu_{j,t}\right)^T\left(x_t-\mu_{j,t}\right)}\Big/\left(2\pi\right)^{\frac{n}{2}}\left|\sigma_{j,t}\right|^{\frac{1}{2}} \tag{2}$$

Where $\eta\left(x_t,\mu_{j,t},\sigma_{j,t}\right)$ is the j Gaussian distribution at time t, $\mu_{j,t}$ and $\sigma_{j,t}$ represent mean and variance respectively, $\omega_{j,t}(\sum_{j}^{K}\omega_{j,t}=1)$ is weight. If the value of x_{t+1} satisfy any Gaussian distribution, the point is the background. Conversely, it is the foreground, and then we get foreground mass of the image.

Moving feature and shape feature of the mass. In order to get more accurate analysis of the mass, we introduce the moving information into mass segmentation. (u,v) denotes the optical flow vector of the current pixel of mass, where u and v represent horizontal velocity and vertical velocity respectively. The process is as follows: Firstly, we established objective function according to the assumption of the consistency of the gray level and gradient, and then we got the optical flow vector by calculating the minimum of the objective function. The objective function is:

$$E(u,v)=\int_{\Omega}(w^T J_{\rho}(\nabla_3 f)w+\alpha(|\nabla u|^2+|\nabla v|^2))dxdy \tag{3}$$

Where $\nabla_3 f$ denotes the spatiotemporal gradient $(f_x,f_y,f_t)^T$, the vector field w describes the displacement, and the weight α serves as regularization parameter. The matrix J_ρ is the structure tensor, it is expressed as:

$$J_\rho=K_\rho*\begin{pmatrix}J_{11}&J_{12}&J_{13}\\J_{21}&J_{22}&J_{23}\\J_{31}&J_{32}&J_{33}\end{pmatrix}=K_\rho*\begin{pmatrix}I_x^2&I_xI_y&I_xI_t\\I_xI_y&I_y^2&I_yI_t\\I_xI_t&I_yI_t&I_t^2\end{pmatrix} \tag{4}$$

Where K_ρ is a Gaussian with standard deviation ρ, $*$ denotes convolution. The optical flow vector is the corresponding (u,v) when the objective function is minimal. Eq. 3 is calculated by Lagrange method as:

$$\Delta u-\frac{1}{\alpha}(K_\rho*(I_x^2)u+K_\rho*(I_xI_y)v+K_\rho*(I_xI_t))=0,\quad \Delta v-\frac{1}{\alpha}(K_\rho*(I_y^2)v+K_\rho*(I_xI_y)u+K_\rho*(I_yI_t))=0 \tag{5}$$

Eq. 5 is a nonlinear equation, we transfer it to linear equations in order to get a solution. Then a finite difference approximation to the Eq. 5 is given by

$$\sum_{j\in N(i)}\frac{u_i-u_j}{h^2}-\frac{1}{\alpha}(J_{11i}u_i+J_{12i}v_i+J_{13i})=0,\quad \sum_{j\in N(i)}\frac{v_i-v_j}{h^2}-\frac{1}{\alpha}(J_{21i}u_i+J_{22i}v_i+J_{23i})=0 \tag{6}$$

We got the unknown quantity (u_i,v_i) using iteration solution of the Gauss - Seidel algorithm [3]. The k iteration result is shown as Eq. 7.

$$u_i^{k+1}=\frac{\sum_{j\in N^-(i)}u_j^{k+1}+\sum_{j\in N^+(i)}u_j^k-\frac{h^2}{\alpha}(J_{12i}v_i^k+J_{13i})}{|N(i)|+\frac{h^2}{\alpha}J_{11i}},\quad v_i^{k+1}=\frac{\sum_{j\in N^-(i)}v_j^{k+1}+\sum_{j\in N^+(i)}v_j^k-\frac{h^2}{\alpha}(J_{12i}u_i^k+J_{13i})}{|N(i)|+\frac{h^2}{\alpha}J_{22i}} \tag{7}$$

Where, h is the size of the grid, $N(i)$ denotes the number of neighbors of pixel i that belong to the image domain. After obtaining the optical flow, we form the moving feature vector of mass H by an eight dimensional vector. H is normalized to $[0,1]$, and divided into eight bins to form an eight dimensional data. We input the vector to SVM [4], and obtain the people counting model.

Experimental Results

In this section, the program runs on the computer in which the CUP is Intel Pentium 2.3 G and the memory is 2G. We realize this program by using VC+OPENCV for the test of many different type

videos including scenes containing occlusion. The frame rate is 33fps/s, and the resolution is 720*576 in the set of videos.

As shown in Fig. 1, the optical flow is used to get internal movement direction in the mass, and the large mass is segmented into two masses through the direction difference. In general the large mass contains more people, and the little mass contains few people. We also can see that the strength of the optical flow information is also directly reflects the number of people, because the speed of people is similar in the scenes. The energy of optical flow about mass can reflect the people number in mass indirectly.

The experiment analyses the confusion matrix [5] to evaluate the algorithm performance as Eq. 8.

$$PR = TP/(TP+FP), \quad RE = TP/(TP+FN), \quad F = 2PR \cdot RE/(PR+RE) \tag{8}$$

As shown in Table 1, the value F and PR are over 95%. The experimental results confirm that our approach significantly improves the accuracy of people counting.

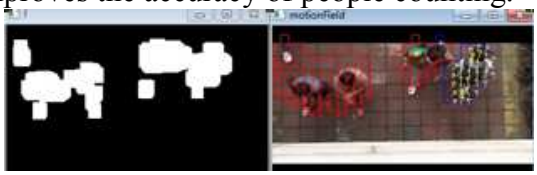

Fig. 1. The influence of the optical flow distribution to the segmentation

Table 1 The result of people counting

Video name	Actual line (in + out)	The thread count (in + out)	TP	FP	FN	PR（%）	RE（%）	F（%）
single direction1	12+0	12+0	12	0	0	100	100	100
two direction 3	29+37	29+37	66	0	0	100	100	100
two direction 4	32+28	32+28	60	0	0	100	100	100
two direction 5	28+18	29+17	45	1	1	97.82	97.82	97.82

Conclusion

The novel method is proposed in complex scenarios with the vertical camera. We integrate the optional flow intensity information of moving people and the size of the mass area to form the feature of mass, and we put the feature into the SVM for people counting analysis. The result show that, the energy and shape information of mass are adequately considered in the algorithm, so the accuracy is close to 100%.In the later study, we will consider joining foreground analysis strategies without shadow to the algorithm for mass information, in order to improve the detection rate.

Keywords: cloud storage security; identity authentication; key separation; encryption strategy

Abstract. With the continuous expansion of the scale data storage, cloud storage technology for its high performance and low cost to get a lot of attention and support. However, the security issues of cloud storage data hinder its further promotion. For the current cloud storage applications of data stored encrypted, a cloud storage encryption scheme based on the separated key and encryption policy is proposed. By strengthening the data encryption key management and data encryption algorithm, the system achieves a more secure storage of data assurance in the technical level.

Cloud storage encryption technology

Encryption technology is the main storage data encryption security measures taken, but also the most used means confidentiality. Specific process is: First, the data is encrypted, then the data stored ciphertext to a storage device; in obtaining data, first remove the data ciphertext, and then use the decryption key for decryption. Common data encryption[1] modes include static data and dynamic data encryption mode encryption mode.

Static data encryption mode refers to the user data is encrypted locally and then sent to the ciphertext cloud storage server. The advantages are: the user to save the decryption key, high degree of safety. Disadvantages are: client computing capability have higher requirements, and only the user's data is encrypted.

Dynamic Data encryption mode, refer to cloud storage server encrypts all data and storage. The advantages are: a unified data encryption key management, ease of use. Disadvantages are: data security depends entirely on cloud storage service provider, from the user's control.

There is no effective data encryption method[2], it is possible to achieve both the encrypted data on the server side, but also a good guarantee the security of stored data.

To ensure that the server is encrypted cloud storage data storage security, the biggest problem is how to solve two problems[3]: First, the management of data encryption key, the second is the data encryption algorithm selection problem.

Traditional cloud storage encryption scheme

Working principle diagram of traditional cloud storage encryption scheme, as shown in Fig.1.

The workflow of traditional cloud storage encryption scheme is as follows:

(1) Users upload the master key to the cloud storage server.

(2) Treating the stored data when encrypted data generated by encrypting the first key generation data encryption key k; secondly based on a single encryption algorithm to encrypt data; Finally, the ciphertext data storage. The ciphertext is stored on the server while the data encryption key.

(3) When the decryption of the ciphertext data, the first data encryption key to decrypt the ciphertext; Secondly, according to the corresponding decryption algorithm to decrypt the data; Finally, the data returned to the user.

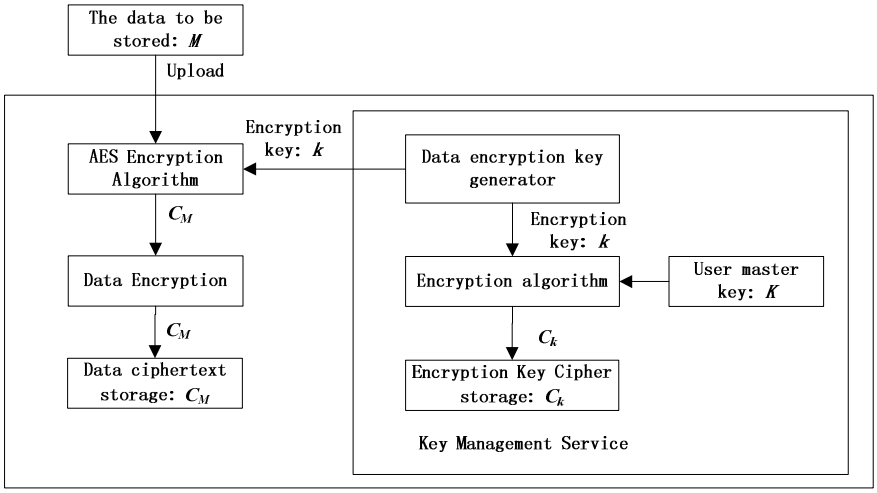

Fig.1: The traditional cloud storage encryption scheme works diagram

While traditional cloud storage encryption scheme allows users to store data in the form of cipher text, but because of its intrinsic unity of key management and data encryption algorithm, making the security of data there is a certain risk. First, because the data encryption keys and master keys stored in the cloud storage service side, hackers can impersonate the user access to the user's data by stealing the user's login account. Secondly, all the data stored on the server side of the cloud cloud storage service managers are transparent. Again, the data encryption algorithm unity such that all the user data using the same encryption algorithm. If the algorithm itself is not high safety performance, safety data for all users are faced with the threat.

A Cloud Storage Encryption Scheme Based on Separated Key and Encryption Policy

For traditional security issues that exist in the cloud storage encryption scheme is proposed based on cloud storage encryption scheme and encryption key separation strategy. The program key and the encrypted virtual management services for the separation of the data encryption key management, and increase the data encryption algorithm selection strategy[4].

Working principle diagram is shown in Fig.2.

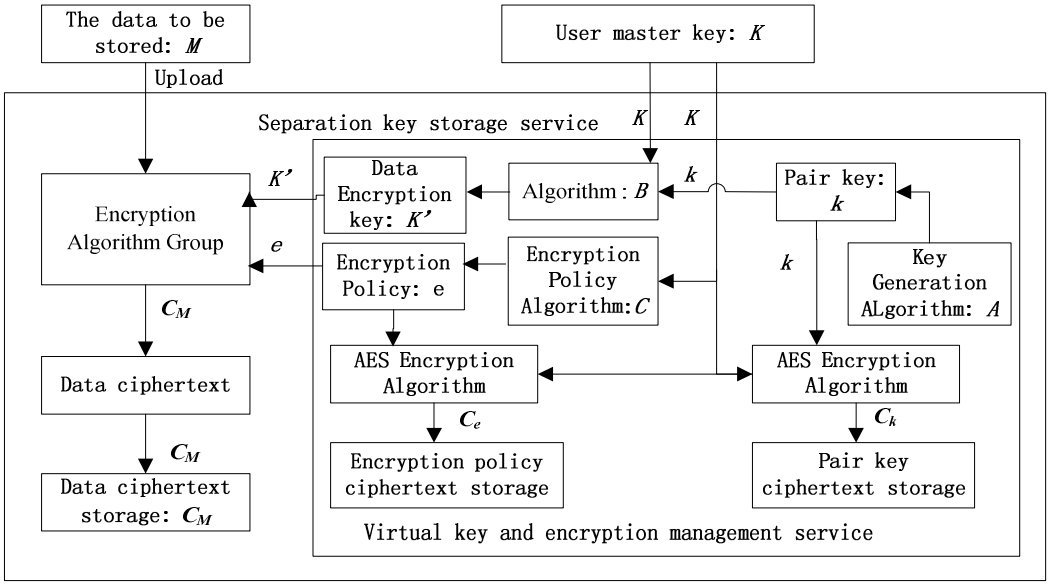

Fig.2: Based on the work of separation and encryption key strategic cloud storage encryption scheme schematic

Encryption Policy: take user master key and timestamp as input pairs to generate encryption policy with encryption policy algorithm, and store the encrypted ciphertext policy on the server.

Pair Key: generated by the key algorithm to automatically generate and together generate data encryption keys and user master key by the algorithm B, and then treat the stored data to be encrypted.

Encryption Algorithm Group: Provide a variety of encryption algorithms and corresponding decryption algorithm, and given the corresponding encryption policy. Users select the appropriate encryption policy based on the encryption algorithm used to encrypt the data and decrypt the encryption policy to select the corresponding decryption algorithm.

Workflow-based separation and encryption key strategic cloud storage encryption scheme is as follows:

(1) When treating the stored data is encrypted, first generate a key pair k; secondly paired with the primary key generation key data encryption key together; then generated based on the user master key encryption policy; then encryption policies and data encryption key as input select an encryption algorithm to encrypt the stored data treatment; last ciphertext data storage. Among them, the pair of keys and encryption policy is stored encrypted on the server.

(2) When the data is decrypted ciphertext, first paired with the user master key encryption key ciphertext and decrypt ciphertext strategies; secondly regenerate the data decryption key K according to the user master key and pairing key '; then data encryption and decryption key strategy as an input, select the corresponding decryption algorithm to decrypt the ciphertext data; Finally, the data returned to the user.

Based on the key separation and encryption strategy of cloud storage encryption scheme, the relationship between key separation and encryption strategy as shown in Fig.3:

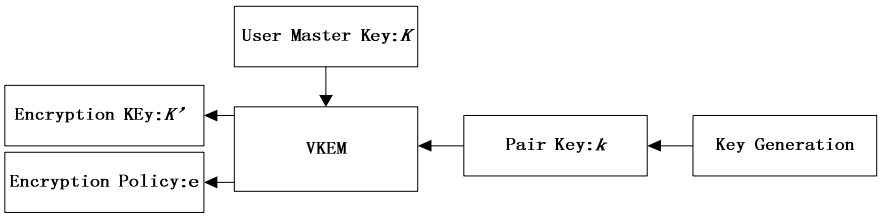

Fig.3: Separation and encryption key strategic relationship diagram

Data encryption key consists of two key components: one is the master key, saved by the user; another is paired keys kept by the cloud storage server. When VKEM processing data encryption, the user must give the key to the master key and matching encryption key data is calculated, and then treat the stored data encryption. Data encryption keys and master keys are not stored in any form on the server side, thus greatly increasing the difficulty of stealing data encryption keys to ensure the security of data.

Data encryption algorithm is determined by the encryption policy, and encryption policies and keys generated by the user's home, the master key is not stored in any form on the server side, so even get still decrypt ciphertext encryption policy, can not be used in what kind of data encryption algorithms, adds data encryption algorithms are difficult to break, to ensure the security of data.

Performance Testing

We use a simple cloud storage service system LAN built, experimental data upload and download via the browser and the cloud server. In order to improve service performance separation and encryption key management server strategy, they were placed on three physical servers for deployment. Based on this framework, for data transfer test.

Encryption cost ratio: the encryption key management services and encryption policies proportion of time spent entire data encryption services takes time.

Decryption cost ratio: encryption key management services and encryption policies take time to decrypt data services accounted for the proportion of total time spent.

Fig.4 shows the two cloud storage data encryption scheme to be stored in a different size than the encryption takes under 5 decryption program for the two cloud storage data to be stored in a different size than the lower of cost and decryption.

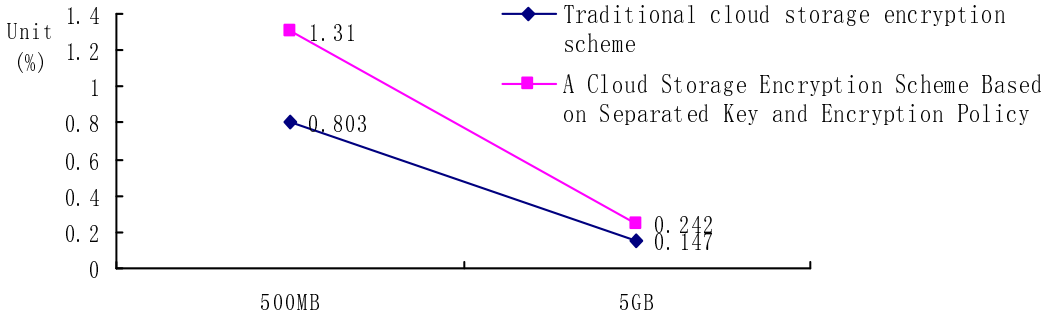

Fig.4: Encryption cost ratio under different sizes

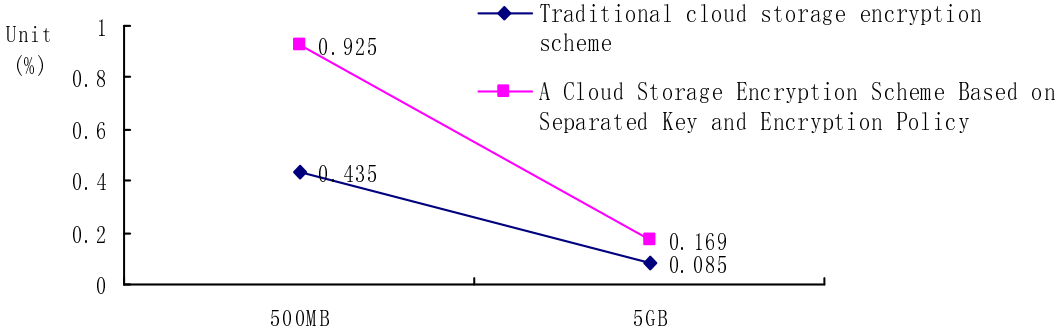

Fig.5: Decryption cost ratio under different sizes

Judging from the test case data, whether the data encryption process or decryption of data, loss of key computing performance separation cloud storage encryption policy-based encryption scheme introduced very small, little effect on the overall performance. Moreover, this affects the performance of cloud storage will increase the amount of data the user is getting smaller. Therefore, the proposed cloud storage encryption scheme, the performance loss is calculated by minimizing server privatized data, to better protect the security of the cloud storage of user data, reducing the ciphertext to crack the degree of risk, so for safe cloud storage applications is entirely acceptable.

Summary

In this paper, because of the traditional security issues that exist in the cloud storage encryption scheme, a cloud storage encryption scheme based on the separated key and encryption policy is proposed. By using this scheme the encryption key separation strategies to enhance the data encryption key management and encryption algorithms to ensure the privacy of user data cloud, improved safety performance. Finally, the test results show that, it not only ensures high security of data, but also has a good performance.

Keywords: Multi-attribute decision-making; quadratic programming; weight; priority

Abstract. The multi-attribute decision making (MADM) problem is studied, in which the information about attribute weights is unknown and the decision maker (DM) has avail preference information on alternatives. Firstly, a quadratic programming model based on the minimum deviation between the objective decision-making information and the subjective preference information on alternatives is established. Secondly, the existence of solution to the model is proved and the calculated formula of the attribute weights are given, thus the overall values of the alternatives are gained by using the additive weighting method. Based on these values, the selecting the best on alternatives is processed. Finally, a practical example is illustrated to show the feasibility and availability of the developed method.

Introduction

Up to now, a lot of good results [1−3] have been obtained on the researches of the MADM problems without preference information on alternatives. However, in the real process of decision-making, the decision maker (DM) often has the subjective preference information on alternatives [4−8]. This is what is called the MADM problems with preference information on alternatives (MADM-PA, for short). As a result, the MADM-PA problems have been investigated and some methods of solving theses problems have been proposed recently. Such as, the MADM-PA problems that the information about attribute weights is unknown completely, the attribute values are numbers and the DM's preference relation on alternatives take the form of fuzzy complementary judgment matrix [3−4] or reciprocal judgment matrix [5−6] are studied in Refs [3-6]. A non-linear programming method is presented. The MADM-PA problem that the information about attribute weights is unknown completely and the DM has ordering preference on alternatives is investigated in Ref [7]. The method based on sensitivity analysis is presented. The MADM-PA problem, in which the attribute weights are interval numbers and the DM's preference relation on alternatives are in the fuzzy complementary judgment matrix and reciprocal judgment matrix is studied in Ref [8]. A linear programming approach is presented. The MADM-PA problem that the information about attribute weights is unknown and DM has avail preference information on alternatives is investigated in this paper. In our method, Section 2 gives simple representation of the studied problem. The principle and approach of decision-making are given in section 3. An application example is given in section 4. Finally, some concluding remarks are included.

Representation of problem

The basic model of the MADM-PA that will be studied in this paper can be represented as follow:

- Let $X = \{x_1, x_2, \cdots, x_n\}$ be a set of $n\ (\geq 2)$ feasible alternatives, and denote $N = \{1, 2, \cdots, n\}$;
- Let $S = \{s_1, s_2, \cdots, s_m\}$ be a set of $m\ (\geq 2)$ attributes, and denote $M = \{1, 2, \cdots, m\}$;
- Let $\omega = (\omega_1, \omega_2, \cdots, \omega_m)^T$ be the vector of weights, such that, $\omega_i \geq 0, \sum_{i=1}^{m} \omega_i = 1$;

- Let $v_j, j \in N$ be the DM's subject avail preference information on alternatives;
- Let $A=(a_{ij})_{m\times n}$ be a decision matrix, where a_{ij} is the attribute value for the alternative x_j with respect to attribute $s_i, i \in M, j \in N$.

In general, there are benefit attribute values I_1, cost attribute values I_2, steady attribute values I_3 and interval values I_4 in the MADM and the different attribute values may be the different dimension. Obviously, $M = I_1 \bigcup I_2 \bigcup I_3 \bigcup I_4$. For the convenience of decision-making, we need to deal with all attributes in dimensionless units and normalize each attribute value. This can be achieved by normalizing a_{ij} in the matrix $A=(a_{ij})_{m\times n}$ into a corresponding element r_{ij} in the matrix $R=(r_{ij})_{m\times n}$ with the normaled formulas in Ref [3].

Then using the simple additive weighting method[1], the overall value of alternative x_j can be expressed as $z_j(\omega)=\sum_{i=1}^{m}\omega_i r_{ij}, j \in N$ (1)

Principle and approach of decision-making

Because the attribute weights are unknown, we need determine it for ranking priorities or selecting the best on alternatives. Considering both the objective decision-making information and the subjective preference information on alternatives is consistent. However, there always exist some differences in them. Therefore, their deviation must be minimum to obtain the reasonable attribute weights. Considering all alternatives are fair. Therefore, the following quadratic programming model can be established:

$$\begin{cases} \min d^2(\omega)=\sum_{i=1}^{m}\sum_{j=1}^{n}(r_{ij}-v_j)^2\omega_i^2 \\ s.t.\sum_{i=1}^{m}\omega_i=1, \omega_i \geq 0 \end{cases} \quad (2)$$

Theorem If $\sum_{j=1}^{n}(r_{ij}-v_j)^2>0, i \in M$, then the model(2) has only solution.

Prove The Lagrange number multiply function $L(\omega,\lambda)=\sum_{i=1}^{m}\sum_{j=1}^{n}(r_{ij}-v_j)^2\omega_i^2+2\lambda(\sum_{i=1}^{m}\omega_i-1)$ is constructed.

let $\begin{cases} \frac{\partial L}{\partial \omega_i}=2\sum_{j=1}^{n}(r_{ij}-v_j)^2\omega_i+2\lambda=0 \\ \frac{\partial L}{\partial \lambda}=2(\sum_{i=1}^{m}\omega_i-1)=0 \end{cases}$;

This is, $\begin{cases} \sum_{j=1}^{n}(r_{ij}-v_j)^2\omega_i+\lambda=0 \\ \sum_{i=1}^{m}\omega_i=1 \end{cases}$, $i \in M$.

Scilicet,

$$\begin{bmatrix} \sum_{j=1}^{n}(r_{1j}-v_j)^2 & 0 & \cdots & 0 & 1 \\ 0 & \sum_{j=1}^{n}(r_{2j}-v_j)^2 & \cdots & 0 & 1 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & \sum_{j=1}^{n}(r_{mj}-v_j)^2 & 1 \\ 1 & 1 & \cdots & 1 & 0 \end{bmatrix}_{(m+1)\times(m+1)} \begin{bmatrix} \omega_1 \\ \omega_2 \\ \vdots \\ \omega_m \\ \lambda \end{bmatrix}_{(m+1)\times 1} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}_{(m+1)\times 1} \tag{3}$$

Let $B_{mm} = diag[\sum_{j=1}^{n}(r_{1j}-v_j)^2, \sum_{j=1}^{n}(r_{2j}-v_j)^2, \cdots, \sum_{j=1}^{n}(r_{mj}-v_j)^2]_{m\times m}$;

$W_{m1} = (\omega_1, \omega_2, \cdots, \omega_m)^T$; $0_{m1} = [0, 0, \cdots, 0]^T$; $E_{m1} = (1, 1, \cdots, 1)^T_{m\times 1}$.

Then(3) equal to (4):

$$\begin{pmatrix} B_{mm} & E_{m1} \\ E_{m1}^T & 0 \end{pmatrix}\begin{pmatrix} W_{m1} \\ \lambda \end{pmatrix} = \begin{pmatrix} 0_{m1} \\ 1 \end{pmatrix} \Leftrightarrow \begin{cases} B_{mm}W_{m1} + \lambda E_{m1} = 0_{m1} \\ E_{m1}^T W_{m1} = 1 \end{cases} \tag{4}$$

Let $D_k = \begin{vmatrix} \sum_{j=1}^{n}(r_{1j}-v_j)^2 & 0 & \cdots & 0 \\ 0 & \sum_{j=1}^{n}(r_{2j}-v_j)^2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \sum_{j=1}^{n}(r_{kj}-v_j)^2 \end{vmatrix}_{k\times k}$, $k \in M$.

Because $\sum_{j=1}^{n}(r_{ij}-v_j)^2 > 0, i \in M$,we have $D_k > 0 (k = 1, 2, \cdots, m)$, thus B_{mm} is a positive definite matrix. This is, B_{mm} is inverse, then the model (2) has only solution. The W_{m1} is solved as follow:

Because the B_{mm} is inverse, then we can obtain W_{m1} by solving the matrix equations (4)as follow:

$$W_{m1} = \frac{B_{mm}^{-1}E_{m1}}{E_{m1}^T B_{mm}^{-1} E_{m1}} = \omega \tag{5}$$

Substituting ω into equation (1), we can get the overall value $z_j(\omega)$ of the alternative x_j. Obviously, the bigger the vales of $z_j(\omega)$ is, the better the corresponding alternative x_j.

Based on the above discussion, we will give the solving processes of the proposed method by using a practical example in the following section.

Practical example

An investment company is planning to exploit a new product and there are five investment alternatives $x_j (j = 1, 2, 3, 4, 5)$ to be considered. The main attributes of evaluating the alternatives are listed as s_1: investment amount, s_2: expected net profit amount, s_3: venture profit amount; s_4: venture loss amount, respectively. Among these four attribute, s_2 and s_3 are of benefit attributes, s_1 and s_4 are of cost attributes. The attribute values of each alternative are listed in Table1 (attribute unit

is10000$), suppose that the DM has avail preference information on alternatives as $v_1 = 0.82, v_2 = 0.85, v_3 = 0.90, v_4 = 0.75, v_5 = 0.95$. Please determine the best investment alternative.

Table1 Original decision matrix A

	x_1	x_2	x_3	x_4	x_5
s_1	5.2	10.08	5.25	9.72	6.60
s_2	5.2	6.70	4.20	5.25	3.75
s_3	4.73	5.71	3.82	5.54	3.30
s_4	0.473	1.599	0.473	1.313	0.803

$$R = (r_{ij})_{4\times5} = \begin{bmatrix} 0 & 1 & 0.010 & 0.926 & 0.287 \\ 0.492 & 1 & 0.153 & 0.508 & 0 \\ 0.407 & 0 & 0.784 & 0.071 & 1 \\ 1 & 0 & 1 & 0.254 & 0.707 \end{bmatrix}$$

Step1 Using normaled formulas [3] ,we can get the normalized decision matrix R from Table1 as top:

Step2 By solving the equation (5), the weight vector of the attributes is obtained as $\omega = (0.102, 0.300, 0.200, 0.398)^T$.

Step3 By (1), the overall value $z_j(\omega)$ of the alternative x_j as follow:

$z_1 = 0.627$; $z_2 = 0.402$; $z_3 = 0.602$; $z_4 = 0.362$; $z_5 = 0.511$.

Thus the ranking priorities of the corresponding alternatives is $x_4 \prec x_2 \prec x_5 \prec x_3 \prec x_1$, this is, the best alternative is x_1 .

Conclusion

In this paper, we propose a new method to solve the MADM -PA problem that the information about weights is unknown and the DM's avail preference information on alternatives. The core of this method is to determine the attribute weights based on a quadratic programming model and applied the project evaluation in the field of venture investment. Not only it can reflect both the objective information and the DM's subjective information, but also it has the advantages of simple operation and easy to implement on a computer.

Keywords: manifold-based learning; dimensionality reduction; face recognition; orthogonal semi-supervised

Abstract. In recent years, a variety of manifold-based learning dimensionality reduction techniques have been proposed, which attempt to project the original data into a lower dimensional feature space by preserving the local neighborhood structure. Among them, marginal fisher analysis (MFA) achieved high performance for face recognition. However, the optimal basis vectors obtained by MFA are non-orthogonal and MFA usually deteriorates when labeled information is insufficient. In order to resolve these problems, we present a new method called orthogonal semi-supervised marginal fisher analysis (OSMFA), which not only extracts all the orthogonal discriminant vectors but also preserves the global structure of labeled and unlabeled samples to learn a better subspace for classification. Experimental results on ORL database demonstrate the effectiveness of the proposed algorithm.

Introduction

Over the past few decades, a large volume of feature extraction techniques have been proposed and most of them have been successfully applied to many applications such as face recognition and so on. One classical technique is the linear discriminant analysis (LDA) [1] that has been shown to be successful on classification problem, such as face recognition. But, when the data is distributed in a nonlinear way, LDA may fail to discover essential data structures. Another technique of manifold-based learning called locality preserving projections (LPP) [2] has been proposed for dimensionality reduction. LPP can preserve the intrinsic geometry of data and yield an explicit linear mapping suitable for training and testing samples. However, LPP has an inherent limitation, that is, the objective function of LPP is to minimize the local quantity, which has no direct relationship to classification. Yan et al. [3] proposed marginal fisher analysis (MFA), which achieved high performance for face recognition. MFA overcomes limitations of LDA and LPP. However, MFA neglects efficacy of the unlabeled samples and the optimal basis vectors obtained are nonorthogonal, which are believed to have more discriminating power [4–6]. In the real world, the labeled samples are often very difficult and expensive to obtain. The supervised methods cannot work well when there is a lack of training samples; in contrast, unlabeled samples can be easily obtained. Therefore, in such situations, it can be beneficial to incorporate the information which is contained in unlabeled samples into face classification. Many algorithms, e.g. semi-supervised discriminant analysis [7] and semi-supervised method based on local and global preserving [8], can efficiently handle the labeled and unlabeled samples to learn a better subspace for classification.

In this paper, we present a new method called Orthogonal Semi-supervised Marginal Fisher Analysis (OSMFA), which can preserve the global structure of labeled and unlabeled samples and at the same time derive all the orthogonal optimal discriminant vectors. The effectiveness of the proposed algorithm is demonstrated by experiments on the ORL face database.

MFA

Assume that X is a n dimensional face sample set with N elements belonging to C classes. Denote x_i the jth image, and N_l number sample in the class i .Thus, we have $\sum_{i=1}^{C} N_i = N$ and $X = [x_1 \cdots x_i \cdots x_N]$. Marginal fisher analysis (MFA) develops a new criteria to characterize intra-class compactness and inter-class separability, in which, the within-class compactness is represented as the sum of distances between each sample and its intra-class neighbors, and the between-class separability is characterized as the sum of distances between each point and its inter-class neighboring points.In MFA, the within-class scatter matrix is defined as:

$$\begin{aligned} S_w^L &= \sum_{i=1}^{N}\sum_{j=1}^{N} R_W(i,j)(x_i - x_j)(x_i - x_j)^T \\ &= X(D_W - R_W)X^T \\ &= XL_W X^T \end{aligned} \tag{1}$$

Where

$$R_W(i,j) = \begin{cases} 1, & \text{if } i \in N_{k1}(j) \text{ or } j \in N_{k1}(i) \\ 0, & \text{otherwise} \end{cases} \tag{2}$$

Where $N_{k1}(i)$ indicates the index set of the k_1 nearest neighbors of the sample x_i in the same class.

The between-class scatter matrix is defined as

$$\begin{aligned} S_B^L &= \sum_{i=1}^{N}\sum_{j=1}^{N} R_B(i,j)(x_i - x_j)(x_i - x_j)^T \\ &= X(D_B - R_B)X^T \\ &= XL_B X^T \end{aligned} \tag{3}$$

where

$$B_{ij} = \begin{cases} 1, & \text{if } (i,j) \in P_{k2}(c_i) \text{ or } P_{k2}(c_j) \\ 0, & \text{otherwise} \end{cases} \tag{4}$$

where $P_{k2}(c)$ denotes the index set of the k_2 between-class nearest neighbors of the sample x_i .

The objection function of MFA is defined as:

$$W = \arg\min_{w} \frac{tr(W^T S_W^L W)}{tr(W^T S_B^L W)} \tag{5}$$

Eq. 5 can be solved by generalized eigenvalue decomposition

$$S_W^L w_i = \lambda_i S_B^L w_i \quad i = 1,2,\cdots,l \tag{6}$$

OSMFA

Assume that $X = [X_1\ X_2]$ are composed of labeled and unlabeled samples. $X_1 = [x_1 \cdots x_i \cdots x_N]$ are composed of labeled samples and $X_2 = [x_{N+1} \cdots x_i \cdots x_{N+M}]$ are composed of unlabeled samples. In order construct the objective function using labeled and unlabeled data, we give total-scatter matrix S_T and the local scatter matrix S_L, respectively. S_T is defined as follows:

$$S_T = \frac{1}{2(N+M)(N+M)} \sum_{i=1}^{N+M}\sum_{j=1}^{N+M} (x_i - x_j)(x_i - x_j)^T \tag{7}$$

S_L is defined as follows:

$$S_L = \frac{1}{2(N+M)(N+M)} \sum_{i=1}^{N+M}\sum_{j=1}^{N+M} H_{ij}(x_i - x_j)(x_i - x_j)^T \tag{8}$$

Affinity matrix H_{ij} is defined as follows

$$H_{ij}=\begin{cases}\exp(-\left\|x_i-x_j\right\|^2/t), & \text{if } i\in N_k(j) \text{ or } j\in N_k(i)\\ 0, & \text{otherwise}\end{cases} \tag{9}$$

Then, we give a new criterion as follows:

$$W=\arg\min_{WW^T=I}\frac{tr(W^TS_W^LW+W^TS_LW)}{tr(W^TS_B^LW+W^TS_TW)} \tag{10}$$

The new objective function is constructed by labeled and unlabeled samples, so we call it as Orthogonal Semi-supervised Marginal Fisher Analysis (OSMFA). Equation.10 can be solved by generalized eigenvalue decomposition

$$(S_W^L+S_L)w=\lambda(S_B^L+S_T)w \tag{11}$$

The projection axes can be selected as the generalized eigenvectors $w_1,w_2,\cdots,w_d$ of $(S_W^L+S_L)w=\lambda(S_B^L+S_T)w$ corresponding to d smallest eigenvalues.

However, since the matrix $(S_B^L+S_T)^{-1}(S_W^L+S_L)$ is asymmetric, the basis vectors $\alpha_1,\alpha_2,\cdots,\alpha_r$ are not orthogonal. The orthogonal basis vectors to Eq. 10 can be obtained through the Gram–Schmidt orthogonalization [6]. OSMFA can be described in the following steps.

Step 1: Compute S_W^L and S_B^L according to Eq. 1- 4;

Step 2: Compute S_T and S_L according to Eq. 7-9;

Step 3: Then, compute $(S_B^L+S_T)$ and $(S_W^L+S_L)$,respectively;

Step 4 : Solve Eq. 10 by generalized eigenvalue decomposition, then we can obtain the basis vectors $\alpha_1,\alpha_2,\cdots,\alpha_r$ .Compute orthogonal matrix W of the $\alpha_1,\alpha_2,\cdots,\alpha_r$ using the Gram–Schmidt orthogonalization.

Experimental Results

To demonstrate the effectiveness of our method, experiments were done on the ORL face database. The ORL face database is composed of 40 distinct subjects. Each subject has 10 images under different expression and different views. The size of each face image is 92×112. From the ORL face database, we randomly selected l (3,4,5,6,7) images from each person for training, while the rest of the images of each person were selected for testing. OSMFA algorithm is compared with MFA, ODLPP and SDA [6,7]. We repeated the experiments 10 times in ORL face database. The average accuracies were taken as their final recognition rates. The recognition rates of the four algorithms mentioned above are shown in Table 1.

Table 1 Recognition rates on the ORL face database (%)

methods	training samples/class				
	3	4	5	6	7
OSMFA	91.28	93.17	95.50	97.28	97.67
MFA	90.75	92.38	94.70	96.62	96.83
SDA	89.33	91.16	93.40	94.12	95.17
ODLPP	88.61	90.18	91.25	94.64	95.25

From Table 1, we find that OSMFA is the most efficient dimensionality reduction method, and is much more efficient than SDA, MFA and ODLPP. The one reason is that OSMFA method eliminates the dependence among discriminant vectors to improve the performance of MFA. The other is that the criterion of OSMFA is optimal compared with criterions of SDA, MFA and ODLPP.

Conclusions

The idea behind OSMFA is to learn orthogonal optimal discriminant vectors and preserves the global structure of labeled and unlabeled samples in addition to separating labeled samples in different classes from each other. As a result, OSMFA is more effective and efficient in face recognition.Experiments on face data show that the proposed algorithm has more discriminative power in comparison with SDA, MFA and ODLPP.

The proposed algorithm is still linear technique for feature extraction. Therefore, they may not sufficient to deal with some applications that have non-linear relationships.One of our future works includes using the so-called kernel trick to generalize the proposed algorithm. The orther is that we will focuse on the incremental learning methods [9] and the incremental feature set will be utilized to improve its processing speed and thus new algorithm can be developed that are suitable for real-time classification and recognition.

Keywords: Geomagnetic matching; Artificial fish swarm algorithm; Affine transformation; Inertial navigation system; Extended Kalman filter.

Abstract. Geomagnetic matching (GM) is a new developmental technology in recent years. For resolving the cumulate errors of position, velocity, attitude in an inertial navigation system (INS), utilizing artificial fish swarm algorithm (AFSA) to carry on GM is proposed, and then the attained matching position regarded as measurement of filter to achieve the emendation of INS. Firstly, affine transformation model between inertial and real trajectories is displayed and the principle of INS/GM is explained. Secondly, the state of artificial fish (AF), distance and food consistence are defined afresh, and then the flow chart based on AFSA is given. Lastly, simulation analysis is performed in actual geomagnetic reference map (GRM). The results show that the algorithm actualizes the GM when the inertial system exist position, velocity and attitude error, that is the algorithm got the optimized global solution, with that, the data fusing is finished with the results that not only reduce error evidently but also verify the validity and feasible of the algorithm.

Introduction

For reducing the dependence on GPS[1], insuring the navigation system security, reliability and independence, GM has become a hotspot in the field of the current navigation domain [2], which possesses the advantage of all weather, good concealment, low energy consumption and so on along with the advance of magnetic theory and measurement technology. GM navigation is enormous action for successive navigation especially for underwater vehicle so as to prevent exposing trace.

The geomagnetic navigation system is applied in many aspects as shown in references [3-6]. At present, the technology of the aviation geomagnetic survey have been mature and the error compensation technology of measurement data is also achieved abundant fruits, thus provide condition for the development GM. GM algorithm can be divided into two kinds: one kind is related extremum algorithm, the other is filtering algorithm. The first algorithm applied widely because it can be solved the biggish position error. Accuracy of GM decides the precision of geomagnetic navigation directly. Reference [7] simulates the feasibility of the first algorithm by using Housdorff distance as related criteria. From the feature space, similarity metric, search space and search strategy four aspects of GM is established, and presents a mathematical description of GM[8]. Reference [9] breaks through traditional search strategy, adopts intelligent search strategy to analyze the feasibility about the GM.

AFSA is an intelligent algorithm in recent years and widely used in communication, signal processing and other subjects[10, 11]. From the intelligent search strategy into consideration, the article introduces the AFSA to develop the GM, and then the attained matching position can be seemed as measurement of Kalman filter to accomplish the correction of INS.

INS error model and principle of GM navigation

INS error model

The INS error is accumulated, so after a period of time the INS need to error emending, and then the carrier can move on. The shape of INS trajectories and real trajectories are different because of

attitude error and velocity error. So the corresponding relation between the INS and real trajectories is established by affine transformation [8], shown as follows

$$\begin{bmatrix} x_{rk} \\ y_{rk} \end{bmatrix} = \alpha \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix} \begin{bmatrix} x_{ik} \\ y_{ik} \end{bmatrix} + \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix} \tag{1}$$

where (x_{ik}, y_{ik}) are INS coordinates values and (x_{rk}, y_{rk}) are real trajectory coordinates values. Δx, Δy denote shift factor, α is scaling factor, mainly used to adjust the speed error, and θ is rotation factor, mainly used to adjust the attitude error.

Principle of INS/GM navigation

Integrated navigation system of INS/GM consists of INS, geomagnetic sensor, GRM and PC etc., mainly contains two function parts, shown in Fig. 1: the part Ⅰ and part Ⅱ. The part Ⅰ is GM technology, which adopts geomagnetic sensors and GRM as assistant tools. The real-time geomagnetic measurement data attained by sensors and at the same time, combined position information of INS, a series of geomagnetic data extracted form the GRM, and then the best matching position gained according to correlation algorithm. The part Ⅱ is data fusing technology, which utilizes best position information as measurement of Kalman filter to filter for integrated navigation system, in this way the INS error restrained. The following depicts the specific principle of GM and data fusing.

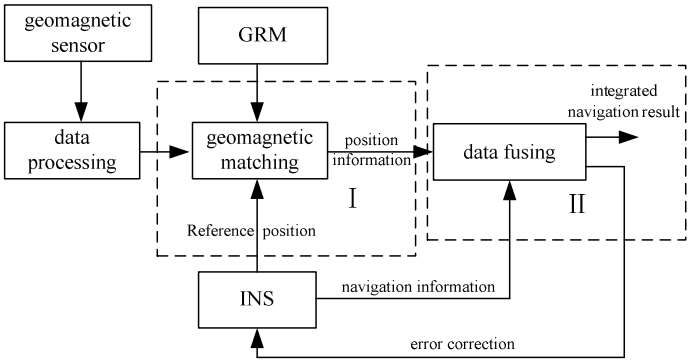

Fig. 1 Schematic diagram of INS/geomagnetic integrated navigation system

AFSA and its application in GM

The basic idea of AFSA is to imitate the fish behaviors such as preying, swarming, following so as to reaching the global optimum[10, 11].

Concept of AF based on GM

(a) AF Individual state By Eq. (1) we know that the four parameters namely α, θ, Δx, Δy required to gain, so the individual state of AF can be expressed as Eq. (2)

$$X = (\alpha, \theta, \Delta x, \Delta y) \tag{2}$$

(b) AF Distance The Euclidean distance is the most commonly used for calculating the distance of AF, the expression is $D = (\sum_{i=1}^{n} |x_i - y_i|^2)^{1/2}$, x, y represent two AFs, and i is the serial number of variables, n is the total number of variables. By the expression we can see that the distance is the simple cumulate of all the variables, but neglect the difference of the variables dimension, and then the practical significance of the distance is hard to illuminate. Aiming at this situation, it is essential to make some changes to the Euclidean distance, as shown in Eq. (3)

$$D = (\sum_{i=1}^{n} \left| x_i - y_i \middle/ Visual_i \right|^2)^{1/2} \tag{3}$$

where $Visual_i$ denotes ith value of $Visual$, the expression reveals the relative size of variables correspond to the $Visual$, which can more reflect the distance between two AFs objectively.

(c) AF Food consistence The food consistence of AF is the objective function value. g_{Ni} is geomagnetic data sequences extracted from GRM based on the INS position after affine

transformation, and H_N is measured data sequences of geomagnetic sensors. In combination with the basic principle of GM, AF food consistence expression is as follows

$$foodconsistence = N / \sum_{k=1}^{N} \left(H_N(k) - g_{Ni}(k) \right)^2 \tag{4}$$

where N is the total number of matching sequence, and the value of food consistence is in direct proportion to the effect of individual state of AF, namely the larger food consistence is, the better individual state of AF is. Compared Eq.(4) with MSD algorithm[9], it is find that Eq.(4) is the reciprocal value of MSD algorithm.

Application of AFSA in GM

After a period of autonomous navigation, velocity error, attitude error and position error can be reasonably estimated, then the range of the scaling factor α, rotating factor θ and shift factor Δx, Δy can be fixed on. In succession, the initial AFs are produced and different fish behaviors are performed and then the optimal state X of AF is obtained. The detailed flow chart is shown in Fig. 2.

Experiment schematic design and analysis

Experiment schematic design

Experiment schematic design based on two conditions: (1) Three discontinuous GRMs (matching areas), shown as in Fig. 3, area A, B and C. (2) Developing path planning for INS entered the matching area propitious. Schematic design of path planning presents in Fig. 3, the black dot and red dot are initial point and end point separately, the blue line connecting initial point with end point is the planned path.

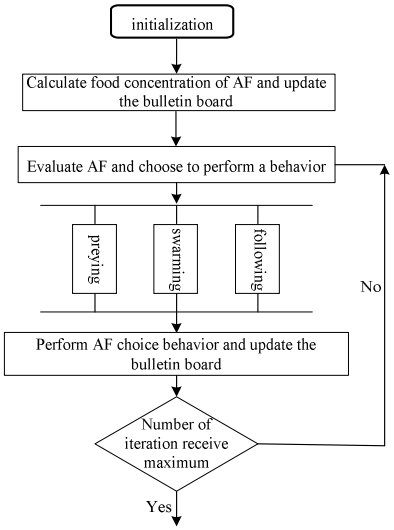

Fig. 2 Flow chart GM based on AFSA

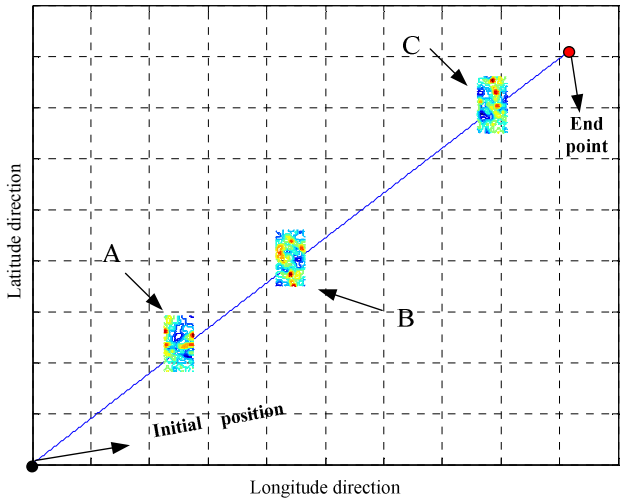

Fig. 3 Schematic design of path planning

Test and analysis of GM

The total number of GRM (area A) grid is 100×110, X and Y axis are shown as longitude and latitude respectively, the grid spacing is 0.001°. The INS and real trajectories are produced by inertial system and tracking generator respectively. The value of real trajectories on the GRM makes up of measurement value of geomagnetic after adding some Gaussian noise.

Setting moving trajectories is uniform linear motion, the velocity is 20m/s, and initial errors are 0. Sensor starts work after 40min, measurement interval of sensor is 10s, sample points are 20. In this time slice the errors of INS are shown in Fig. 4, Fig. 5 and Fig. 6.

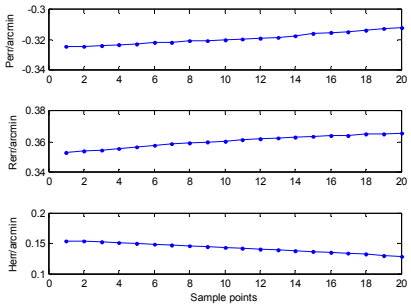

Fig. 4 Attitude errors

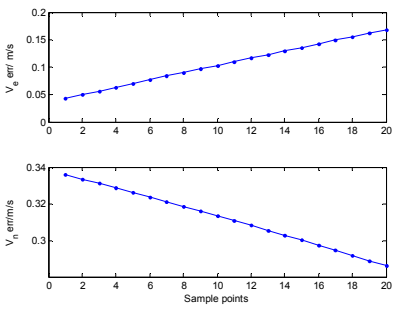

Fig. 5 Velocity errors

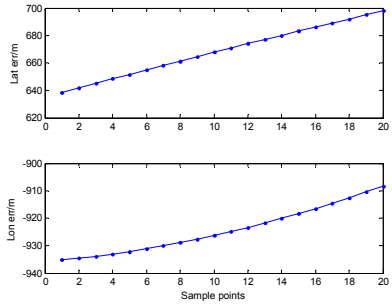

Fig. 6 Position errors

Fig. 4 shows the attitude errors in the process of sampling, the Fig. 5 shows the velocity errors, Fig. 6 shows the position errors. It is found that the transform relation of Eq. (1) is rational, so the key of GM is to seek four factors of α, θ, Δx, Δy. GM experiment is depicted as follows, the parameters of algorithm listed in table 1.

Table 1 Simulation parameters of proposed algorithm

Parameters	value	Parameters	value	Parameters	value
total number	500	try number	3	scope of scaling factor	[0.9,1.1]
iteration	30	crowd factor	0.518	scope of rotate factor	[-3°,3°]
vision	(0.04,0.05°,2.5,2.5)	noise of sensor	(0, 25)		
step length	(0.01,0.0125°,0.6,0.6)	scope of shift factor	[-5000,5000]m		

Simulation results are shown as Fig. 7 and Fig. 8. Fig. 7 reveals the matching result of algorithm on the whole. Fig. 8 displays the idiographic matching results in latitude and longitude direction, and the results show the matching precision less than 100m.

In general, matching result of the last sample point can be seemed as the final matching result, namely, latitude error is about 20m, and longitude error is about 50m in this experiment. It is obligatory point out that the matching results shown in Fig. 7 and Fig. 8 are just once simulation experiment. For evaluating the reliability of algorithm, the 20 trials of simulation experiment put in practice, likewise the matching result of the last sample point seemed as the final matching result.

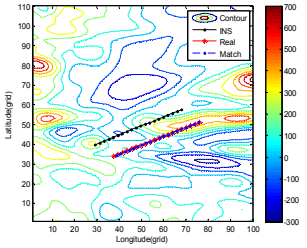

Fig. 7 Matching results

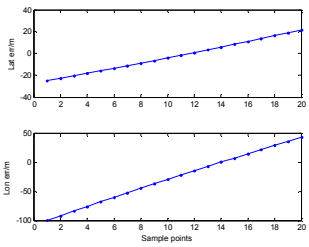

Fig. 8 Latitude and longitude error after matching

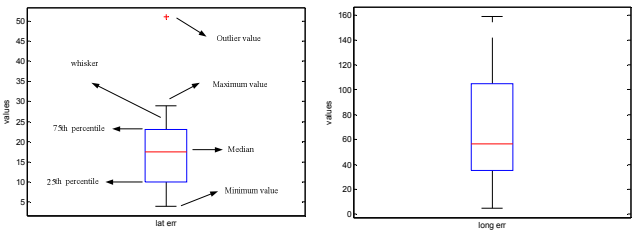

Fig. 9 Box figure of error statistics results
(a) Latitude error (b) Longitude error

By the method of mathematical statistics the error results are shown in Fig.9. Fig. 9(a) depicts the detailed meanings and we can see that there is only one outlier value, which is about 50m within a grid (100m). From Fig. 9(b) we can see that there is no one outlier value in longitude direction, and the maximum value is about 160m. So we validate the convergence property and randomness with the statistics method. Thereupon, taking example by area A validates feasibility of the algorithm.

INS/GM integrated navigation

Data fusing is implemented by EKF after attained the matching position. Combine with the position of GRM shown in Fig. 3(a), the three matching time slice are fixed on 40~43min, (has shown in section of 4.2), 70~73min and 127~130min. Sampling point of every time slice is 20 and sampling interval time is 10s. Ultimately the results of data fusing are demonstrated as Fig.10.

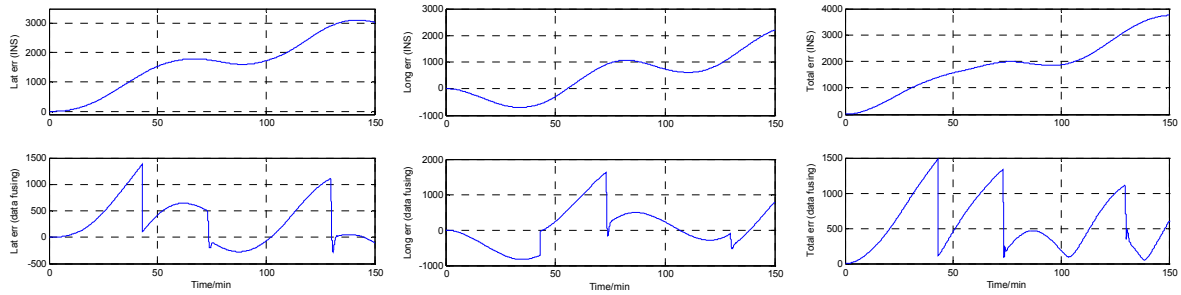

Fig. 10 Contrast between INS and data fusing
(a) Latitude error (b) Longitude error (c) Total error

Fig. 10 displays the contrast results between INS and data fusing, which denotes that the errors of latitude, longitude and total are accumulated by pure INS, but errors are restrained by data fusing. In this way, without the GPS, merely rely on three GRMs, the INS error is revised by using path planning, which decreases the difficulty of engineering application, and has great significance for successive navigation of carrier especially for underwater vehicle so as to avoid exposing trace.

Conclusion

We have presented AFSA application research in GM field, which achieved error emendation of INS by imitating the fish behaviors such as the preying, swarming, following and leaping etc. Combine with the actual circs of GM, the state, distance of AFs were revised and operation steps, flowchart were brought forth. Based on the practical position condition of three GRMs, schematic design was done, and took area A for example GM was test and analyzed, following the results show that the proposed method has a strong robustness and convergence character, in the last place, the data fusing was proceed, from the results we can see that the INS error gained the restrained effectively, which is of great importance to the uninterrupted navigation of carrier especially underwater vehicle. Additionally, because of algorithm's feasibility, we may use it to test practical carrier in the future.

Keywords: Currency Crisis; Wavelet; Support Vector Machine.

Abstract. A currency crisis is typically a kind of rare event, but it hurts sustainable economic development when it occurs. A novel method of wavelet-based support vector machine (SVM) is proposed to predict financial crisis events for early-warning purposes in this paper. In the proposed method, currency exchange rate, a typical currency indicator that usually reflects economic fluctuations, is first chosen. Then a wavelet decomposition algorithm is applied to the currency exchange rate series. Using the wavelet decomposition procedure, some details and features of the currency exchange rate series, with different scales, can be obtained. Using these details and features, a wavelet-based SVM learning paradigm is used to predict future currency crisis events, based upon some historical data. For illustration purpose, the proposed wavelet-based SVM learning paradigm is applied to exchange rate data of two Asian countries to evaluate the state of currency crisis. Experimental results reveal that the proposed wavelet-based SVM learning paradigm can significantly improve the generalization performance relative to some popular forecasting methods.

Introduction

Economic crises occurred over the past several decades have showed that currency crises are usually in the core position of economic crises. Therefore, currency sectors' stability is key to maintain economic stability and currency crisis may cause a economic crisis. The European currency crises in 1992, the Mexican peso crisis in 1994, the Asian crises in 1997–98, the Russian currency crisis in 1998, the American subprime mortgage crisis in 2007 and the Greek debt crisis in 2010 were indeed telling the fact. To prevent future crises, researchers have tried to predict the crisis by identifying common factors underlying exchange rate instability. However, existing models suffer from a number of weaknesses which include the need for a large number of controlling parameters, difficulty in obtaining a stable solution, the danger of over fitting, dependence on the selection of indicators and single-scale learning process. These problems usually lead to poor generalization to the out-of-sample data despite impressive in-sample results[1-3]. SVM and Wavelet analysis can solve the above problems.

In 1995, a novel neural network algorithm, called support vector machine (SVM), was developed by Vapnik and his co-workers [4]. Unlike most of the traditional neural network models which implement the empirical risk minimization principle, SVMs implement the structural risk minimization principle which seeks to minimize an upper bound of the generalization error rather than minimize the training error. Based on this principle, SVMs achieve an optimum network structure. This results in better generalization performance than other neural network models.

In most previous studies, stock index , interest rate or currency exchange rate is selected as model input. In this paper, the currency exchange rate is chosen. A possible drawback of a single-scale learning process is that it is sometimes inadequate for complex and difficult problems, e.g., some non-stationary and non- linear real-world problems, and often yields poor generalization performance[5]. To alleviate the potential problem of poor generalization, the original exchange rate data are decomposed into multiple intrinsic components by DWT algorithm before applying the SVM

algorithm . These decomposed independent componets can represent different factors affecting currency exchange rate movement. Therefore, the components are considered as independent variables for constructing a pattern recognition model. These components, with different scales, are used for SVM training to improve performance, relative to single series-based models training. Therefore, the proposed new learning paradigm is seen as multiscale SVM learning algorithm and overcomes many shortcoming of the existing approaches by virtue of the advantages of SVM and wavelet analysis.

Overview of SVM

Based on statistical learning theory, Vapnik puts forward support vector machine. Its basic idea is to construct an optimal separating hyperplane with high classification accuracy . A brief description of the SVM algorithm is provided as follows [6].

Given the training data set $D=\{(x_i,y_i)\}_{i=1}^{M}$, where $x_i \in R^n$ is an input vector and $y_i \in \{-1,1\}$ denotes a target label. In the linear separable case, SVM algorithm is to find an optimal separating plane $w \cdot x + b = 0$. In the nonlinear separable case, a nonlinear function $\Phi(x)$ must be applied to map input space to a higher dimensional feature space and the constrained optimization model of soft-margin based on SVM is as follows :

$$\text{Minimize } \frac{1}{2}w^T w + C\sum_{i=1}^{M}\xi_i \text{ , Subject to } \begin{cases} y_i[w^T\Phi(x_i)+b] \geq 1-\xi_i \ (i=1,\cdots,M) \\ \xi_i \geq 0 \ (i=1,\cdots,M) \end{cases} \tag{1}$$

Where ξ_i is a slack variable and C is a tuning parameter. By applying the Lagrangian technique to Eq. (1), we can obtain its dual problem as follows:

$$\text{Maximize } \frac{1}{2}\alpha^T Q\alpha - e^T\alpha \text{ , Subject to } \begin{cases} 0 \leq \alpha_i \leq C \ (i=1,\cdots,M) \\ y^T\alpha = 0 \end{cases} \tag{2}$$

where e^T is a vector of all ones, Q is a positive semi-definite matrix and α_i is Lagrange multiplier. The element Q_{ij} of Q is equal to $y_i y_j K(x_i,x_j)$, where $K(x_i,x_j)=\Phi(x_i)^T\Phi(x_j)$ is called kernel function. In the paper, we adopt the Gaussian kernel function, i.e. , $K(x,y)=\exp(-\|x-y\|^2/2\sigma^2)$, where σ is the kernel width. Based on the above analysis, we can obtain the classifier function:

$$f(x)=sign(\sum_{i=1}^{M}a_i y_i K(x,x_i)+b) \tag{3}$$

Overview of wavelet analysis

Wavelet analysis provides an advanced technique to decompose an original time series into a hierarchical representation of multilevel time series [7]. Wavelet analysis focuses on scale-based analysis, which allows the use of long time intervals where we want more precise low-frequency information, and shorter regions where we want high-frequency information. This paper choose scales and positions based on powers of two, i.e. the span of each coarser level is double to that of the previous level, which is the so-called dyadic scales and positions. Wavelet multi-resolution analysis produces a family of hierarchically organized decompositions. For example, an original time series $x(t)$ is decomposed into an approximation $a_1(t)$ and a detail $d_1(t)$, and $a_1(t)$ can be decomposed into an approximation $a_2(t)$ and a detail $d_2(t)$ similarly. This decomposition process can be iterated with successive approximations being decomposed in turn. At the end of this sifting procedure, the time series $x(t)$ can be expressed by

$$x(t)=a_J(t)+d_J(t)+\cdots+d_1(t) \tag{4}$$

where J is the number of details, $a_J(t)$ is the approximation, which is the main trend of $x(t)$, and $d_j(t)(j=1,\cdots,J)$ are the details, which are orthogonal to each other. Thus, one can achieve decomposition of the data series into several intrinsic components.

Wavelet-based multiscale SVM

As earlier noted, SVM are a new kind of neural network technique based on the structural risk minimization (SRM) principle and are widely used in many practical problems. However, a major challenge in SVM is how to make the trained SVM possess good generalization ability, i.e. they can generalize well for cases that were not included in the training set. The key is how to determine the parameters of the kernel function. The SVM with Gaussian RBF kernel is sensitive to the kernel width σ that greatly affects the classification accuracy. We advocate use of the 5- fold cross-validation technique for getting good generalization [8]. But in the cross-validation technique, if SVM is based on a single series representation for the entire training process and the problem is very difficult and complex, the trained SVM by a single series may be inadequate [5]. For this reason, the wavelet-based multiscale SVM is employed to decompose a time series and approximate it by using decomposed components via wavelet analysis framework. Generally speaking, the wavelet-based multiscale SVM paradigm consists of four different steps.

Step I: Data decomposition: The original time series are decomposed into various orthogonal components with a range of scales. The resultant different components form the inputs of SVM.

Step II: The components selection: The different components produced by Step I are input into the SVM for training. In the SVM learning process, internal correlation structures of different componets are explored. Using the explored internal relationships, some important components are selected as final SVM inputs and some unimportant componets that are of little use in mapping of inputs to output are discarded. In this study, principal component analysis (PCA) is used to explore the internal correlation structures of different components.

Step III: SVM training: Once the input patterns, i.e. selected components, are determined , SVM training can be started. In the study, the inputs of SVM are composed of k components (i.e. k components selected by Step II) and the output is -1 or 1. The SVM network training process is performed by Matlab software package.

Step IV: Crisis prediction: After training, we can use the trained SVM to predict future currency crises for out-of-sample data in the final step. When an unknown decomposed vector with k dimensions is input, -1 or 1 is to be picked as the final SVM output, i.e. the pattern to which the given currency crisis state belongs. Particularly, output '-1' is classified as a non-crisis pattern, while output 1 is classified as a crisis pattern, implying that the given currency crisis state might be trapped in a crisis period.

In order to verify the effectiveness of the proposed wavelet-based multiscale SVM approach, two typical Asian currencies—South Korean Won and Thai Baht—which suffered disastrous crisis, are used as testing targets.

Experiments study

For verification purpose, some experiments with data of the two Asian countries (i.e. currencies) are conducted in this study. First, data description and experimental design are presented and then the experimental results are reported.

In our study, we examine the currency crisis conditions and a currency crisis event is defined as a large devaluation of a currency, which far exceeds previous devaluations. From this definition, and some previous studies [9-10], a crisis can be defined as an abnormal event where rate of change (ROC) of exchange rate ($ROC_t = (E_t - E_{t-1})/E_{t-1}$) exceeds an extreme value:

$$F(ROC)=\begin{cases} 1 \ \ if \ \ ROC > \mu_{ROC} + 2.5\sigma_{ROC} \\ -1 \qquad\qquad otherwise \end{cases} \tag{5}$$

where $F(ROC)=1$ represents the occurrence of the currency crisis, and μ_{ROC} and σ_{ROC} are the sample mean and sample standard deviation of the ROC, respectively.

The data used in this study are daily exchange rate data for two currencies (South Korean won, Thai baht) against the US dollar, obtained from the Pacific Exchange Rate Service (http://fx.sauder.ubc.ca/). For purposes of training and testing, we take daily data from January 2, 1996 to December 31, 1997 as in-sample (training periods) datasets (506 observations). We take data from January 2, 1998 to December 31, 1998 as out-of-sample (testing periods) datasets (249observations).

To evaluate the forecasting ability of the proposed wavelet-based multiscale SVM learning approach, we select some popular forecasting methods from the existing literature—such as signal approach [1], logit model [2] , GRNN model [9] for comparative purposes. Table 1 and 2 show the results of comparison for KRW and THB, respectively.Obviously, our method performs the best.

Table 1. Comparison of forecasting performance of KRW for different methods for testing data

Models	Classification accuracy
Signal approach	79.52%
Logit model	78.31%
GRNN model	92.77%
The proposed Multiscale SVM	98.01%

Table 2. Comparison of forecasting performance of THB for different methods for testing data

Models	Classification accuracy
Signal approach	78.95%
Logit model	84.73%
GRNN model	93.82%
The proposed Multiscale SVM	98.72%

Conclusions

In this paper, an wavelet-based multiscale SVM learning approach is proposed for currency crisis forecasting. Applications of the proposed approach to out-of-sample data display surprisingly high accuracy.It reveals that the proposed approach might also be useful for financial practitioners who attempt to build a currency crisis forecasting model or a currency crisis early-warning system. Furthermore, experimental results show that the proposed approach is superior to other classification methods and single-scale neural network learning paradigm, implying that our proposed approach is a promising tool for currency crisis forecasting.

Keywords: Speech Enhancement. Wiener-filtering. Masking Properties of Human Auditory System. Spectrum-Shaping

Abstract. This paper proposes an improved speech enhancement algorithm based on Wiener-Filtering, which addresses the problems of speech distortion and musical noise. The proposed algorithm adopts the masking properties of human auditory system on calculating the gain of spectrum point, in order that the signal in the enhanced speech whose energy is lower than the threshold will not be decreased further and the less distortion will be brought to enhanced speech by the trade-off between the noise elimination and speech signal distortion. What's more, in order to eliminate the "musical noise", a spectrum-shaping technology using averaging method between adjacent frames is adopted. And to guarantee the real-time application, two-stage moving-average strategy is adopted. The computer simulation results show that the proposed algorithm is superior to the traditional Wiener method in the low CPU cost, real-time statistics, the reduction of the speech distortion and residual musical noise.

Introduction

Single channel speech enhancement is one of the research focuses. Many algorithms[1-4] including spectral subtraction method, Wiener filtering, signal subspace method and statistical model based algorithm have been developed and put into use. The Wiener filtering is one of the most well-known and widely used due to its good performance on restraining musical noise. An improved algorithm is given here which gives better speech enhancement under wider range of input SNRs.

Proposed speech enhancement algorithm

Figure 1 shows the block diagram of proposed system.

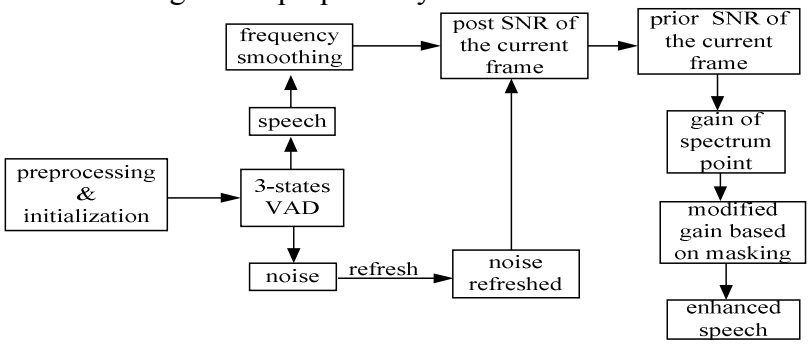

Fig. 1 structure of the proposed enhancement algorithm

VAD(Voice Activity Detect)

The flow diagram of improved VAD algorithm is showed by figure 2.

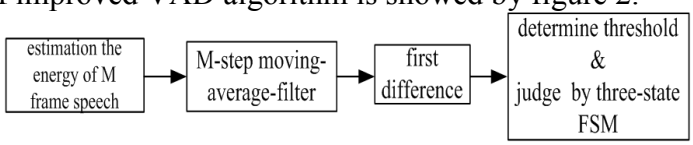

Fig. 2 Flow diagram of improved VAD

The input speech is divided into frames and processed by Hamming window, their energy is estimated. M of them are stored and then input the moving-average-filter. The function $f(x)$ is [5]

$$f(x)=e^{Ax}\left[K_1\sin(Ax)+K_2\cos(Ax)\right]+e^{-Ax}\left[K_3\sin(Ax)+K_4\cos(Ax)\right]+K_5+K_6e^{Sx} \quad (1)$$

Here, parameter A affects the amplitude of its frequency response. Parameter K_1~K_6 affect the shape of the frequency response. Parameter S affects the initial conditions. The output of the moving-average-filter is

$$F_{out}=\sum_{i=1}^{M}(E_i * f_i) \quad (2)$$

where E_i is the energy of M frames. f_i is parameter of the filter(i=1,2,…M).

Figure 3 shows the state transition diagram.

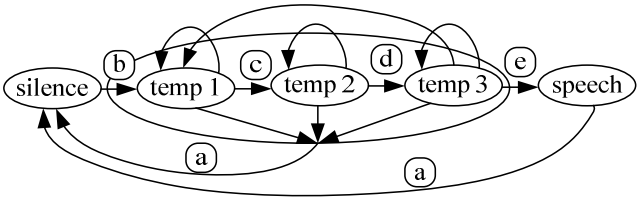

Fig. 3 State transition diagram

During the transition, it starts with silence frame and transits among these states depending on the corresponding conditions a~e. These conditions are described as followed.

a: the output of filter bi is less than the given threshold T_1;

b: the output of filter bi is greater than the given threshold T_1;

c: differential energy between two successive frames is more than the threshold DIF;

d: Duration as the number of the frames whose energy is more than T_1 is greater than the given threshold MAX_Dur;

e: low frequency(i.e. frequency is lower than 400Hz) energy of current frame is greater than the threshold E_{low} and its ratio in total energy is greater than the energy factor ρ.

Calculate the prior SNR

In baseline system, the prior SNR is determined both by "a apriori SNR" of last frame and that of current frame. Relation among them in the Decision-Directed algorithm is determined by

$$\hat{\varepsilon}(p,k)=\alpha\frac{\left|H(p-1,k)X_m(p-1,k)\right|^2}{\Gamma_d(p,k)}+(1-\alpha)P'\left[V(p,k)\right] \quad (3)$$

Where $V(p,k)=\gamma(p,k)-1$, $P[x]=x$ if $x\geq 0$ and $P[x]=0$ otherwise. The parameter α is assumed constant 1 in traditional usage which leads to an inefficiency in noise-varying situation. Thus an improvement is proposed and the definition of cost function J is shown as followed,

$$J=E\left\{\left[\hat{s}(n)-s(n)\right]^2\right\} \quad (4)$$

$\hat{s}(n)$ and $s(n)$ are enhanced speech and pure speech respectively.

Let $\frac{\partial J}{\partial \alpha}=0$, then

$$\alpha=1-f(\varepsilon_{k-1},\gamma_k) \quad (5)$$

The definition of $f(\varepsilon_{k-1},\gamma_k)$ is

$$f(\varepsilon_{k-1},\gamma_k)=\begin{cases}\left|\dfrac{\gamma_k}{\varepsilon_{k-1}}\right|\left(|\gamma_k|<|\varepsilon_{k-1}|,\varepsilon_{k-1}\neq 0\right)\\ \left|\dfrac{\gamma_k*\varepsilon_{k-1}}{|\gamma_k|^2+|\varepsilon_{k-1}|^2}\right|\left(|\gamma_k|>|\varepsilon_{k-1}|\right)\end{cases} \quad (6)$$

When ε_{k-1} and γ_k are both zero, α can be any value belong to [0, 1]. ε_{k-1} and γ_k are calculated by the following formulas.

$$\varepsilon_{k-1} = \frac{\lambda_s(k-1)}{\lambda_d(k-1)} \tag{7}$$

$$\gamma_k = \frac{|y_k|^2}{\lambda_d(k)} \tag{8}$$

$\lambda_s(k)$ and $\lambda_d(k)$ are energy of speech and noise respectively. y_k is the noise-corrupted speech signal.

Human hearing physiological and philosophical characteristics such as masking effects[6][7] are taken into considerations while determining the gain obtained from the assumed algorithm.

Let the auditory threshold of each frequency point is described by $F = [f_0, f_1, ...f_{M-1}]$, f_k is the threshold of kth frequency. The modified gain $\hat{G}(n)$ considering the masking properties of human auditory system is

$$\hat{G}(n) = M\,\mathrm{ax}\left(G(n), \frac{f_k}{y(n)}\right) \tag{9}$$

Where

$$G(n) = \frac{\varepsilon_k(n)}{1+\varepsilon_k(n)} \tag{10}$$

Spectrum shaping

In order to eliminate the "musical noise"a spectrum-shaping technology using averaging between adjacent frames is adopted. To guarantee the real-time application, two-stage moving-average strategy is adopted.

Suppose the sequence of the frequency samples of the frame going to be smoothed is $S_i = [s_{i,0}, s_{i,1}, ..., s_{i,N-1}]$, N is the number of the frequency points. That sequence of the last frame is $S_{i-1} = [s_{i-1,0}, s_{i-1,1}, ..., s_{i-1,N-1}]$. Then the smoothed sequence of current frame is

$$\hat{S}_i = [\hat{s}_{i,0}, \hat{s}_{i,1}, ..., \hat{s}_{i,N-1}] \tag{11}$$

Where $\hat{s}_{i,j} = \frac{1}{2}(s_{i-1,j} + s_{i,j})$.

What's more, in order to get a better smoothing result, the number of N in most non-real-time application is 3~5. While in real-time application, the number of N is 2~3.

Experimental results

We select a piece of single channel data as pure speech which is saved as 1.wav The speech signal is sampled at 8 kHz and quantified with 16 bits. Gauss White Noise whose mean value and variance are 0 and 1 respectively is added into the speech to get a noise-corrupted speech signal with SNR of 5dB.

The proposed algorithm in the paper divided the mixed signal into frames with 32ms whose offset is 16ms. The order M of Winner filter is 25. Smoothing parameter is 2. In power spectrum subtraction algorithm, parameters α and β are 2.7 and 0.01 respectively. In baseline system of Winner filter, factor of Decision-Directed is 0.99, α and β are 2.7 and 0.01 respectively too, forgetting factor ρ is 0.85. Figure 4~figure 7 showed the initial noise-corrupted speech signal and the results of enhanced speech according to each algorithm above.

Keywords: License Plate Recognition; Edge Detection; License Plate Color Information; Character Feature Extraction; Neural Network

Abstract. In order to improve the license plate recognition accuracy under complex environment, a new license location algorithm combining vertical edge detection, color information of the license plate and mathematical morphology is presented in this paper. For balance of computing load and recognition accuracy, a "200-d" character feature rule is designed, and the "200-d" feature is used as the input of BP neural network to recognize the characters. Based on the above-mentioned methods, a license plate recognition system is set up, which can locate and recognize the license plate effectively, even when the resolution of pictures and the position of vehicles in the pictures are not fixed. Experimental results indicate that the recognition rate of the algorithm reaches 90.5%.

Introduction

License plate recognition is very widely used in intelligent transportation systems. Through the license plate image recognition, vehicles can be indentified automatically. Then the vehicle management, flow control and toll charge can be highly automated. License plate recognition technology includes three main parts, which are license plate location, character segmentation and character recognition. Among them, license plate location and character recognition play key roles in the speed and accuracy of license plate recognition technology. So this paper mainly focuses on license plate location and character recognition.

License plate location technology refers to extracting the license plate image from complex image background. Many license plate location methods have been proposed, such as the method based on texture features [1], edge detection [2], mathematical morphology [3] and image color information [4]. While the images are taken in complex environment, the result of using only a single feature to distinguish the license plate region from background is a hard job. It is because that some license plate features exist in some non-license plate region as well, which will interfere with the result of location. Therefore, the method that combines several features to locate the license plate is becoming more and more popular. Such as Wang et al. [5] combined edge detection with mathematical morphology to analyze the connected domains and got the location rate at 90.833%. Xu et al. [6] combined color information with edge detection. They rough classified the plate region in LAB color space at first, and then got the final result according to the edge detection method. As the images they used are all taken in the same place and resolution on a sunny day, the location rate came to 98.51% in those conditions.

Character recognition algorithms are mainly based on the template matching [7], neural network [8] and support vector machine (SVM) [9]. The template matching method identifies the characters by the comparison between the characters to be recognized and the characters in template library. But this method is more vulnerable to the clarity, resolution and some other factors. Neural network has strong learning ability, with the learning of more samples and training of the network, more defective and distortional characters can be recognized. However, the recognition accuracy based on neural network relies on the character feature extraction technology. Recognition method based on support vector machine (SVM) has high robustness in two-class problem, but it is not sufficient to support multi-class problem. And the recognition rate is dependent on the choice of kernel function, the

change of the data set may lead to the change of kernel function, which would change the rate of recognition.

Unlike the images are usually taken in a fixed toll gate or lane [4,5,6], the experimental images in this paper have no unified limit in resolution and clarity. A license plate location method combining vertical edge detection, license plate color information and mathematical morphology is presented in this paper. The license plate is corrected by Radon transform and the character segmentation is done according to the vertical projection. A "200-d" character feature extraction rule is designed to guarantee the appropriate input for BP neural network. After experiment, the results show that the method presented in this paper could reach a high accuracy of recognition.

Vehicle Image Preprocessing

Before the location of license plate, the vehicle image needs to be preprocessed to improve the image quality and contrast. This paper converts color images to gray images at first. The conversion formula of pixel I(x, y) in the color image is shown as Eq. 1:

$$Gray(x, y) = 0.3R(x, y) + 0.59G(x, y) + 0.11B(x, y). \quad (1)$$

Where x and y are the horizontal ordinate and vertical ordinate of the pixel I. $Gray(x, y)$ is the grey value of point (x, y). $R(x, y)$, $G(x, y)$ and $B(x, y)$ are the R, G, B component of pixel $I(x, y)$.

As there is a lot of noise in the vehicle images, by median filter first, the gray image is preprocessed. The 3×3 filter window is adopted, that is, the 8 neighborhood of pixel $Gray(x, y)$ will be sorted and the pixel value in the middle (No.5) will be the response $g(x, y)$. Preprocessing results are shown in Fig. 1 and all the Chinese characters on license plates are covered by white or black squares in all the images in this paper.

(a)Original RGB Image (b) Image after Preprocessing

Fig. 1 Vehicle Image Preprocessing

License Plate Location

Vertical Edge Detection. The edge feature is very obvious between the background and characters in the license plate region, which is helpful for edge detection. As the seven characters of the license plate are roughly horizontally arranged in the vehicle images, obvious and dense edges are gotten easily in the license plate region through vertical edge detection. Compared to the conventional edge detection, the edge got through vertical edge detection is far more less, which can improve the efficiency of subsequent processing.

Vertical Sobel edge operator is used in this paper, as shown as Fig. 2:

$$\begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix}$$

Fig. 2 Vertical Sobel Edge Operator

Vertical edge detection of the gray image is operated by the operator above mentioned. Then the edges too long or too short are removed because they could not belong to the license plate region. The vertical edge detection image is shown in Fig. 3.

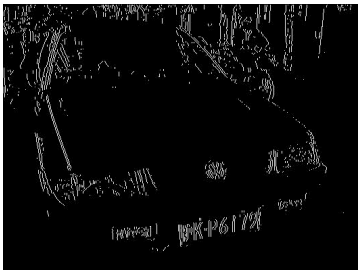

Fig. 3 Vertical Edge Detection Image

Fig 4. Standard Chinese License Plate

Edge Color Pairs Detection. Unlike [5] and some other work, mathematical morphology is not used directly in this paper. Ahead of license plate location, a detection method based on license plate color information is used, so that some interference, such as the characters in non-license plate region, can be removed.

There is a industry standard named GA36-2007 [10] for license plate in China. The specific style of Chinese license plate is shown in Fig. 4.

The color of license plate characters and background has a clear definition according to the GA36-2007. For small cars, the background of license plate is blue and the characters are white; for large cars, the background is yellow and the characters are black; for military and police cars, the background of license plate is white and the characters are black or red; for cars in Embassies, the background of license plate is black and the characters are white. It is obvious that the colors of license plate background and characters come in pairs as follows: blue-white, yellow-black, white-red, white-black and black-white.

Based on the feature that the colors in Chinese license plate come in pairs, the vertical edges are further processed. Only when the edge pixel and its adjacent pixels in the original image match the color pairs rules mentioned above, could the edge belong to license plate region. Other edges will be cancelled because they are treated as non-license plate region.

As the red character only appears once in a white-red license plate and six other characters are all black, the red character has little influence on the location result. Only four kinds of color as blue, yellow, white and black are considered here. The judgment of background and character colors is conducted in HSV space. The range of each component of these four colors is shown in Table 1, where "-" indicates that the value of this component doesn't need to be considered.

Table 1 The Range of HSV Component

	Blue	Yellow	White	Black
H	190-245	25-55	-	-
S	0.35-1	0.35-1	0-0.1	-
V	0.3-1	0.3-1	0.91-1	0-0.35

It is easy to determine whether the pixel color is blue, yellow, white or black by the value of *H*, *S* and *V* component. And it is easy to determine whether the colors of vertical edge pixels are in line with one kind of color pairs among blue-white, yellow-black, white-black and black-white also. Edge pixels meet the rule will be maintained and other edge pixels will be ruled out. Color pairs in the vertical edges of Fig. 3 are detected, and the result is shown in Fig. 5.

Fig. 5 Image after Edge Color Pairs Detection

Mathematical Morphology Method. Then the mathematical morphology method is used to process the edge image. Closing operation comes first and then opening operation operates, so that the dense regions of edges turn into initial connected domains.

According to the aspect ratio of license plate region, some non-license plate region can be cancelled. In this paper, the range of length-width ratio of license plate is set from 2:1 to 4:1. The connected domains which obey this rule will be kept as the candidate license plate region, as shown in Fig. 6.

(a) Initial Connected Domains (b) Connected Domains with Aspect Ratio Limit

Fig 6. Connected Domains

Finally, the license plate image after location is achieved, as shown in Fig. 7.

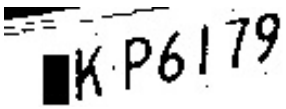

Fig. 7 License Plate Image

License Plate Correction and Character Segmentation

As the license plate image is achieved, characters need to be segmented. But the license plates in vehicle images are usually with a certain angle, which is caused by camera position, as shown in Fig. 7. To solve this problem, Radon transform is used in this paper. If *f(x, y)* is a two-dimensional image, then the definition of Radon transform is shown as Eq. 2:

$$R_\theta(x') = \int_{-\infty}^{+\infty} f(x'\cos\theta - y'\sin\theta, x'\sin\theta + y'\cos\theta)dy \,. \tag{2}$$

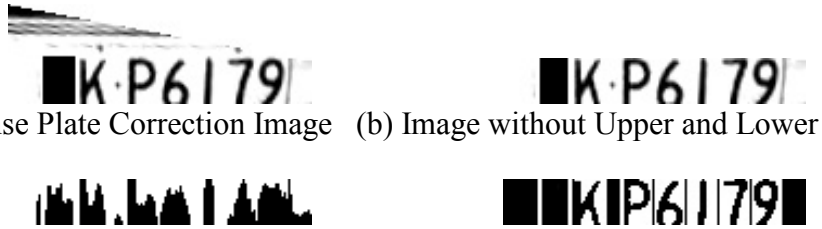
Where $\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}$.

That is, the Radon transform of *f(x, y)* is a line integral parallel to the y' axis. For the license plate image, the value of θ is the tilt angle, which makes the formula (2) to have the smallest accumulation result. It can be used to correct the license plate, as shown in Fig. 8(a).

After correction, there still exist the upper and lower borders of the license plate in the image. The binary license plate image is detected horizontally. If a line contains the character pixels, the value of

pixels will jump at least 14 times in this line. By detecting the image from top to bottom and from bottom to top respectively, any line does not meet the rule will be excluded, as shown in Fig. 8(b).

As the upper and lower borders are removed, vertical projection is adopted in this paper, as shown in Fig. 8(c), and the result of character segmentation is shown in Fig. 8(d).



(a) License Plate Correction Image (b) Image without Upper and Lower Borders

(c) Vertical Projection Image (d) Character Segmentation Image

Fig. 8 License Plate Correction and Character Segmentation Image

Character Recognition

BP neural network is used for character recognition in this paper. As the size of single character made by the character segmentation is not fixed, it is necessary to normalize the characters.

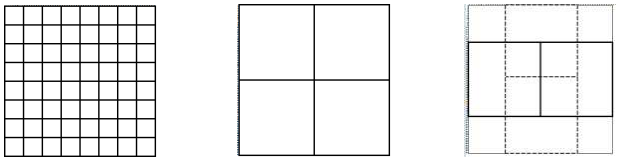
The Design of the "200- d" Character Feature Rule. All the character will be normalized in the same size of 64×64, and BP neural network is used for character recognition in this paper. The character feature is extracted in three steps:

STEP 1: Sum up the value of all pixels in each line and use the sum as a feature, all the 64 lines have 64-d feature.

STEP 2: Sum up the value of all pixels in each column and use the sum as a feature, all the 64 column have 64-d feature;

STEP 3: As shown in Fig. 9(a), there are 64 subblocks in size of 8×8, sum up the value of all pixels in each subblock and use the sum as a feature, all the 64 subblocks have 64-d feature; as shown in Fig. 9(b) and 9(c), there are 8 small subblocks in size of 32×32, sum up the value of all pixels in each subblock and use the sum as a feature, all the 8 subblocks have 8-d feature.

Finally, there are 200-d character feature in total.



(a)8×8subblocks (b)32×32subblocks (c)32×32subblocks

Fig. 9 Subblocks of Characters

License Plate Recognition based on BP Neural Network. There are seven characters in a Chinese license plate. Among them, the first one is a Chinese character, the second character is an English letter and last five characters are all letters or numbers. Therefore, three networks as network of Chinese characters, network of letters and alphanumeric hybrid network are designed. Corresponding to the dimension of the character feature, the number of input nodes is 200. Output is in binary encoding and the number of output nodes is 6. The number of hidden nodes is determined by Eq. 3:

$$h = \sqrt{i \times (o+1)} + 1 . \tag{3}$$

Where h is the number of hidden nodes, i is the number of input nodes and o is the number of output nodes. As i is 200 and o is 6, h should be 37 according to the formula.

The activation function is Eq. 4:

$$\Phi_j(v_j(n)) = \frac{1}{1+e^{(-v_j(n))}}. \tag{4}$$

The learning factor is 0.4, iterations are 50000 and the momentum factor is 0.7.
Input the characters to the trained network, and the final recognition result is shown in Fig. 10.

Fig. 10 License Plate Recognition Result

Experimental Result and Analysis

In this paper, the experiment is conducted on a 2.93 GHz CPU, 2G memory hardware platform, and the software platform is the Windows 7 operating system and the Visual Studio 2008. 200 images are used to verify the effective of our algorithm. Compare with other methods, such as the method combining the edge detection with mathematic morphology, and methods based on single feature as edge detection, mathematical morphology and color information. The location results are shown in Table 2.

Table 2 License Plate Location Result

	Method in this paper	Method combining Edge Detection with Morphology	Method based on Edge Detection	Method based on Mathematical Morphology	Method based on Color Information
Number of Images	200	200	200	200	200
Number of Success	193	185	168	163	154
Location Rate	96.5%	92.5%	84%	81.5%	77%

The resolution and clarity of the images used in the experiments are not fixed. The positions where the license plates locate in the images and the environment where the images taken are not fixed as well. As shown in Table 2, in a total of 200 images, using the method in this paper, 193 images can be successfully located, the location accuracy is 96.5%; using the method combining the edge detection with mathematic morphology, 185 images can be successfully located, the location accuracy is 92.5%; using the method based on edge detection, 168 images can be successfully located, the location accuracy is 84%; using the method based on mathematical morphology, 163 images can be successfully located, the location accuracy is 81.5%; using the method based on the color information, 154 images can be successfully located, the location accuracy is 77%. The result indicates that the two

methods using combination features are better than those only dependent on a single feature, and the location method in this paper is better than the method which just combines edge detection with mathematical morphology.

Table 3 License Plate Recognition Results

	Number of Images	Number of Success	Recognition Accuracy
Method in this paper	200	181	90.5%
Method without Subblock Feature Extraction	200	162	81%

The final recognition result is shown in Table 3. Among the 200 experimental images, using the method in this paper, 181 images are recognized successfully, the recognition accuracy is 90.5%. When only the sum of all the pixel value in each line and column are used as character feature, 162 images can be recognized successfully, the recognition accuracy is 81%. The result in Table 3 shows that the "200-d" character feature extraction method in this paper is better than the method without subblock feature extraction.

Conclusion

This paper proposes a license plate location method combining vertical edge detection, license plate color information and mathematical morphology. Comparing to the method only combining edge detection with mathematical morphology, the method in this paper improves the location accuracy. A "200-d" character feature extraction rule is designed and BP neural network is used in this paper. Compared to the method without subblock features extraction, a better result is gotten. Experimental results indicate that the recognition accuracy of the algorithm reaches 90.5%.

Keywords: Rayleigh Fading Channel, Hidden Markov Model (HMM), channel modeling, finite State Markov Channel (FSMC)

Abstract. In this paper, we proposed a novel hidden Markov model (HMM) to approximate the characteristic of the Nakagami Fading channel. Our study is based on a Hidden Markov Model (HMM). The channel switches between 'good' and 'bad' channel situation. The transition between the sub-states of the channel is governed by a Markov Chain, which some self-return state is hidden. The performance of the model is studied by simulating probability density functions (PDF), cumulative distribution functions (CDF), level cross rate (LCR) and average fade duration (AFD).

Introduction

The technology of telecommunication, especially wireless communication is one of those exciting technologies that has directly and significantly influenced our everyday life. It has changed the dynamics of the working environment and workforce mobility. Without being tethered to a fixed location or formal work-based environment, people can work anywhere.

A key component work of design and build wireless networks is the study of wireless channel models. The modeling of the wireless channel is of great importance to satisfy the operator requirement for network planning, optimization, interference and traffic calculation, as well as frequency planning and neighbors analyses. However, our knowledge of the radio channels encountered in mobile-to-mobile and relay-based systems are still inadequate.

Different approaches could be used to simulate diverse type of channels and their conditions. Generally, mobile radio propagation channels are usually studied in terms of deterministic models, empirical models. Deterministic models [1, 2] are based on a fixed geometry (such as buildings, streets…) and used to analyze particular situations. They provide high accuracy, but require actual analytical path profiles and time-consuming computations. Empirical as well as pure statistical models [3, 4] are based on measurements. They linked to the environment and the parameters of the measurement campaign. Such models are characterized by simple input data and low computational effort, but are usually very poor at extrapolating outside of the measured parameter range and suffer from a classification problem involved in describing the environment. Due to the lack of physical background, such models, however, only apply with good results in environments that are very close to the one they have been inferred from.

This paper presents a novel hidden Markov method to model flat Rayleigh fading channels. The proposed Hidden Markov Model (HMM) is based on the Finite State Markov Channel (FSMC) model [5]. The performance of the model is studied by simulating the probability density functions (PDF), cumulative distribution functions (CDF), level cross rate (LCR) and average fade duration (AFD).

The remainder of this paper is organized as follows: The Nakagami Fading Channel is presented in Section II. In Section III, Hidden Markov Model (HMM) is studied. The joint probability density function and cumulative distribution function of the received envelope amplitudes are analyzed and simulation in Section IV. Section V concludes the paper.

Nakagami Fading Channel

Due to the multipath propagation, the transmitted signals of the receiver are variations of amplitude, phase and angle. The multipath fading gives rise to specific types of degradations of the signal. The variations are characterize by two main manifestations, large-scale and small-scale fading, the later is also known as Rayleigh fading since the fluctuation of the signal envelope is Rayleigh distributed when there is no predominant line of sight between the transmitter and receiver. The sum of multiple independent and identically distributed (i.i.d.) Rayleigh-fading signals have a Nakagami distributed signal amplitude. After k - branch maximum ratio combining (MRC) with Rayleigh-fading signals, the resulting signal is Nakagami with $m = k$. MRC combining of m - Nakagami fading signals in k branches gives a Nakagami signal with shape factor mk.

For Nakagami channels the probability distribution function (PDF) of the channel gain α is [6]:

$$p_\alpha = 2\left(\frac{m}{\Omega}\right)^m \frac{\alpha^{2m-1}}{\Gamma(m)} \exp\left(-m\frac{\alpha^2}{\Omega}\right), \qquad \alpha \geq 0, \tag{1}$$

where $\Omega = E\left(\alpha^2\right)$ is the average received power, m is the Nakagami fading parameter $\left(m \geq 1/2\right)$, and $\Gamma(\cdot)$ is the gamma function. The received CNR γ is then gamma distributed according to the PDF, $p_\gamma(\gamma)$, given by:

$$p_\gamma(\gamma) = \left(\frac{m}{\gamma}\right)^m \frac{\gamma^{m-1}}{\Gamma(m)} \exp\left(-m\frac{\gamma}{\overline{\gamma}}\right), \qquad \gamma \geq 0, \tag{2}$$

where $\overline{\gamma}$ is the average received CNR. The phase ϕ of the Nakagami fading is uniformly distributed over $[0, 2\pi]$.

If $m = 1$, the Nakagami distribution is reduced to Rayleigh distribution, if $m = (1+k)^2 / 2k+1$, the Nakagami distribution is reduced to Rice distribution, and if $m \to \infty$, the Nakagami distribution is reduced to Gaussian distribution.

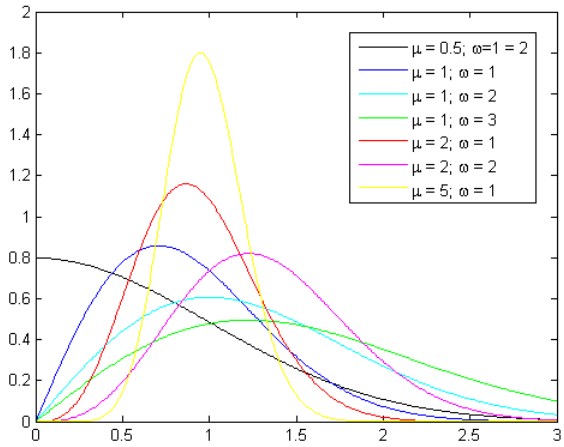

Fig. 1 PDF for Nakagami distribution

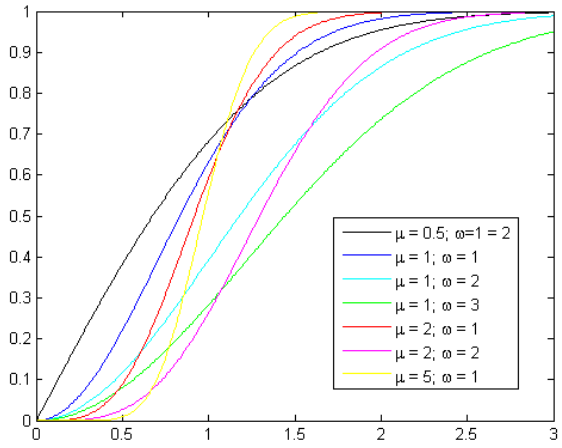

Fig. 2 CDF for Nakagami distribution

Hidden Markov Model

Normally, the Gilbert-Elliot model, the Finite State Markov Channels (FSMCs) and Hidden Markov Models (HMMs) are used to characterize a flat Rayleigh fading channel. In this paper, we used HMM to model the Nakagami channel.

The first order FSMC is inadequate and impractical under very long channel memory **[7]**, due to the fact that in this case the number of states grows exponentially with the process memory.

HMMs are probabilistic function of Markov chains, the results of the observable models is a doubly embedded stochastic process, because one of the stochastic process is not observable, hence the name HMM. The main characteristic of HMM can be outline as follows **[7]**:

1. The number of states in the model is ‘n’, even though some states are ‘hidden’ in practical application. The HMMs processes can be defined by a finite number of possible states by a set $S=\{s_0,s_1,s_2,...,s_{n-1}\}$;
2. The discrete alphabet size is ‘m’, and the set X of the outputs can be represented by as a set $X=\{x_0,x_1,x_2,...,x_{n-1}\}$;
3. The state transition probability distribution matrix $A=\{a_{ij}\}$, where $a_{ij}=p(s_j/s_i)$;
4. The observed symbol probability distribution matrix B is a diagonal matrix whose elements b_j represent the probability $p\{x/s_j\}$, $x\in X$ (is X is discrete);
5. The initial state probability vector is π.

Simulation and Comparison

In this section, we compare the first order statistics (PDF,CDF) and second order statistics (LCR, AFD) of the HMM for Nakagami fading channel. Figure 5 and Figure 6 present the comparison of PDF and CDF for the simulated data and the measured ones respectively. It is perceived that the simulated PDF CDF based on HMM agree well with the measured ones.

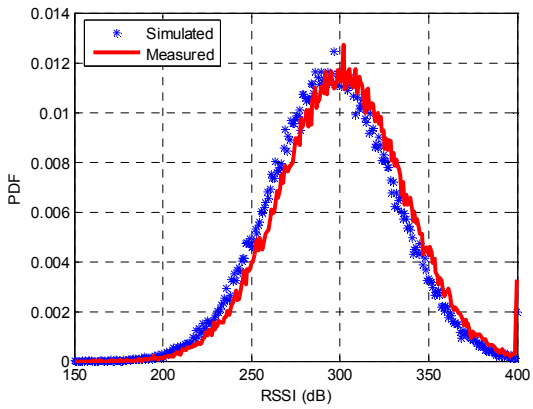

Fig. 1 Comparison of PDFs

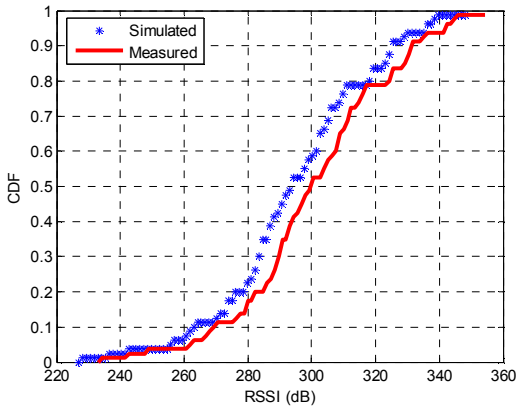

Fig. 2 Comparison of CDFs

It is clear from Fig. 1 and Fig. 2 that there is a significant variance around the mean value. This variation is well described by a lognormal distribution. A maximum likelihood estimate (MLE) of the standard deviation of this distribution is $\sigma_{dB}=3.2$.

Apart from the PDF and the CDF, in order to optimize the digital communication systems, which are required for error correction, other characteristic quantities describing the statistics of mobile fading channels are of importance. These quantities are the level-crossing rate (LCR) and the average duration of fades (AFD).

The system performance changes rapidly when the signal falls below some noise-related threshold and this causes bursts of errors to occur. The rates of occurrence and average length of these error bursts can be estimated from average LCR and AFD of the received signal strength. LCR is defined as the rate at which the RSSI crosses a specified fading level in the positive (or negative) slope. AFD is the average time duration that the RSSI remains below a specified level. Fig. 3 and Fig. 4 present a comparison of LCR and AFD for the simulated data and the measured ones, respectively. It is perceived that the simulated LCR and AFD based on the HMM agree well with the measured ones.

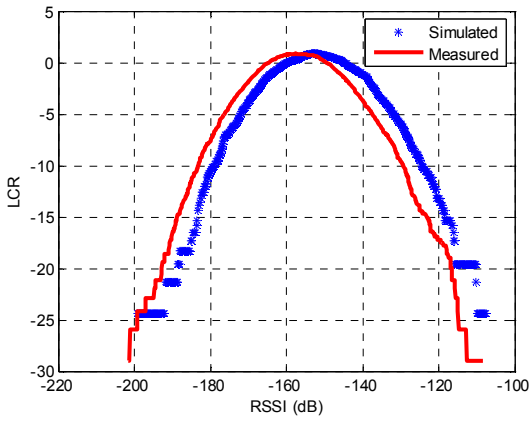

Fig. 3 Comparison of LCR

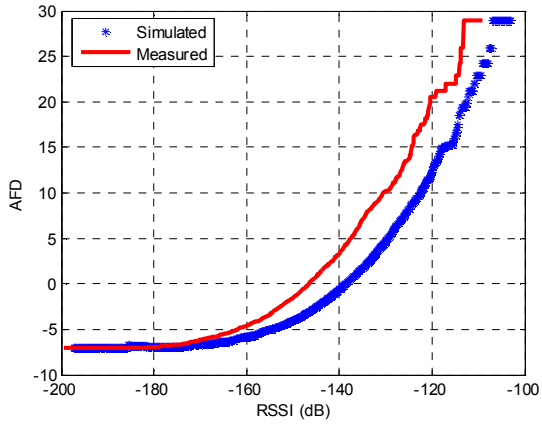

Fig. 4 Comparison of AFD

Conclusion

Extensive research in cellular radio channels has led to the successful deployment of cellular networks. In this paper, we applied the HMM the Nakagami Channel. We have also analysis the channel performance using simulation method. This study shows that the HMM approach can be valuable for the Nakagami channel analyzing and performance evaluation.

The advantages of this model is that it can have a very good fit to experimental data and can obtain closed solutions for several parameter of the model, and all of these advantages could result in better approximation of the model to specific conditions.

Application of Multipurpose Decision Making problem with AHP and Rectilinear Norm in Old Town Renewal Proposals

Bingjiang ZHANG

School of Applied Science, Beijing Information Science and Technology University, Beijing, 100192, China

E-mail: zbj2013ch@163.com

Keywords: AHP; Rectilinear Norm; Allocation Problem; MCDM; Urban Renewal

Abstract. In the process of urbanization, old town renewal is an unavoidable problem. The significance of old town renewal focuses on meliorating residents' physical environment conditions, humane and social environment, and improving urban operation efficiency. Such problem affects not only the development of a certain district, but the benefits of future generations. For city managers, it is difficult to bring up a rational and highly efficient proposal such that related interest bodies would accept, and thus democracy science decision is required. This essay employs AHP to solve the problem of old town renewal proposal assessment, and brings forward the decision-making of multi-objective programming problem based on rectilinear norm allocation problem. Since there is no such paper that systematically and efficiently assess old town renewal proposal by using allocation problem, this paper tries to use this method to "fill out this blank".

Introduction

Nowadays, China's economy and social development are experiencing complicated structural alteration. Urbanization has entered into a stage of accelerated process. Due to the acceleration of urbanization process, new towns are being constructed on the one hand; on the other hand, some old towns cannot satisfy the demands by towns, governments and citizens and thus needed to be redeveloped. In the process of urban development, it has formed its own distinctive cultural, political, and economical system on the one side; although it has written down the path of town development, it reflects the disadvantages left from town development on the other side. In the process of urban development, the movement of population and usage of town resources both result in high population intensity, urban layout chaos, traffic inconvenience and other disadvantages and defects. Some areas cannot sustainably make further development anymore and therefore it cannot meet the needs by the town developments and the economy developments. Along with the consecutive update of the human society development concept, city values and the main point of development continuously happen to have corresponding changes. Today's world has a common approval of society development concept and city value with people oriented and sustainable development, and all of these factors have determined China's urban plans, and the new ideas and principals that urban development must follow.

There are many problems involved in old town redevelopment, which include solving the problems of high population intensity, town layout chaos, inconvenient traffic, and pollution and so on. In the process of old town redevelopment, it is difficult to solve those problems if we merely rely on the government, because citizens, professionals and other residents have their own expectations and each of these group will be affected when participating old town renewal at different stage. Since every single doable proposal will never fulfill all personal considerations and expectations, it is going to be a difficult and complicated process to make up a sustainable and renewable suggestion. It is needed to pick up a compromising proposal with which most people are satisfied from a bunch of proposals with which most people are agreed. Try at most possibility to put forward a most satisfactory urban renewal proposal. In order to make sure the final proposal is persuasive, a scientific method that can

be used to assess urban renewal proposal is needed. This essay will apply AHP and multicriteria allocation problem based on rectilinear norm to solve the problem of sustainable urban renewal.

Old town renewal proposal

First, we bring up a general guideline for old town renewal. In the process of old town renewal, the resources inherited in the town, the future development potential of the town and the problems exists at present must be taken into consideration. Old town renewal is a huge project, and the following elements should be taken into account.

(1) Sustainable development ability. Based on the inherited style of the town, we should consider the "self-hematopoietic function" of the town, which lay a foundation for future town development;

(2) Public participation mechanism. Future residents will gain more opportunities to notice government policy and commit themselves to express their opinions about urban development decision; especially those policies that are related to their living environment and living standards;

(3) Comprehension between related bodies. All class of citizens that reside in future urban areas should be able to follow such urban living style that covers government implements, community supervision, and resident self-consciousness. Related interest groups are compatible and comprehensive with each other;

(4) Residents' living standards are remarkably improved and old town energy and appeal are enhanced. In the process of urban renewal, it is very important to make sure citizens are physically and mentally healthy. Public infrastructures are well matching; public space gets developed and enriched. Old town neighborhoods relationships and social networks are conserved; the sense of identification and the sense of pride that citizens feel about the community are reestablished and enhanced;

(5) Appropriate and balanced use of land. Renewed town should own a broadly mixed-use function which includes working place, residence, Commercial Street, and entertainment infrastructure and so on. These infrastructures and the environment should achieve mutual support to build up a district brimmed with energetic life, business and relaxation;

(6) Perfect traffic facilities. In the renewal region, there should be sideway, highway, bridge, and public railway traffic infrastructure among different infrastructures in order to provide citizens a safe and convenient traffic environment. Traffic lines between renewal region and other region are connected, which includes the connection between the streets inside the region and the main streets outside the region;

(7) Preservation of traditional and positive elements. New exploitation is inevitable in the process of old town renewal. Regions being exploited should enrich and complement the positive characteristics of the renewal region, infrastructures that have remarkable contributions to the characteristics of the town, and some positive elements that truly reflects social personals past achievements. New logos and signs could enhance town characteristics. New framework must be amalgamated with inherited components;

(8) Appropriate humanity environment and urban greening. At the same time the construction of humanity environment is enhanced, urban greening of the renewal region should also be taken into consideration. For example, we should consider what kind of trees and flowers to be planted so that the city image can be better reflected.

According to the old town renewal guidelines mentioned above, a more specific old town renewal proposal is brought up. For urban planning of the old town, the principals discussed in the general guideline only set a direction for old town renewal, and implementers could prepare urban renewal proposal based on this guideline. At the same time the old town renewal proposal reflects the distinct style and geographic characteristics of the town, it should possess common view and sustainable develop ability. Reference [1] and [2] help us set up the goals and principals of sustainable urban

renewal proposal (Table 1). Table 2 gives the goals and specific content of designing principles. Although Table 1 as far as possible shows all sorts of important elements that exist in the old town renewal, distinct humane and geographical areas can be adjusted according to different demands. During the construction, no matter how good the proposal is, it must satisfy the money demanded in urban renewal and acreage limitation of the construction place.

Table 1 Objectives and design criteria for sustainable urban renewal proposal

Objectives	Design criteria
Sociality, SO	Access to public facilities, APF Open and tolerant of public space, OTS Provisions for disadvantaged groups, PDG Conservation of local distinctiveness, CLD Adaptability of development to the changing needs, ADN
Economy, EC	Provision of commercial facilities, CFS Traffic facilities supply and its distribution, TSD Compatibility with neighborhood , COR Citizens job security , CJS
Environmental, EN	Green design, GD Building form and structure, BFS human environment , HE Rehabilitation of repairable properties, RRP
Workability, WO	Construction cost, CC Project implementation, PI Energy utilization, EU

Table 2 The specific contents of evaluation

Objectives and design criteria	Specific contents
SO	It must accord with the demands for human whole development, and it is favorable to the urban social development.
APF	The government offers the society the public articles or public to enjoy. Such as administrative facility, information facility, health facilities, cultural facility, sports facilities, etc.. and if communal facilities meet people's demands and communal facilities can be sufficient used.
OTS	There is not the vacant floor space which does not have buildings and it have the surrounding environment compatibility.
PDG	The social disadvantaged groups included the diseased, young, old, and injured can get government's help. Guarantee the most basic living guarantee of the social disadvantaged groups, and offer the necessary insurance to them, such as the endowment insurance, medical insurance, etc..
CLD	The left characteristic old architecture and celebrity's former residence are protected and offered maintenance.
ADN	In the development of urban area in the future, while the urban area is be developed again or reconstructed, it can adapt to its surroundings, and is favorable to the social development.
EC	The economic development of the urban society, including industry's characteristic and structure.
CFS	There are large-scale markets or comprehensive emporium which can supply with some general merchandise, building materials, ornament materials, etc., and it can offer large-scale food and beverage, amusing, recreation facility, including the construction of significant commercial facilities closely related with people's life such as the commercial square and business street, etc..
TSD	Whether the facilities such as traffic route and station, electromechanical equipment, communication signal, etc. could meet demands of going out of people at ordinary times, and the distribution of traffic facility is more rational.
COR	Area reconstructed and nearby area can well combine it together in order to develop steadily.
CJS	Basic ensured work of urban citizen, for example assign to work for laid-off workers etc..
EN	Urban environmental protection, not only refer to the natural environment, and living environment, social environment, i.e. various interpersonal social relationships such as the political system, cultural tradition, neighbourhood relation, etc..
GD	The floor space of the urban green plants, and if it could beautify the environment.
BFS	The use of the building material and form of the building can bring a kind of comfortable feeling to people.
HE	The environment that can get along harmoniously between men, including people's attitude, idea, faith, cognitive environment, etc..
RRP	After the urban area reconstruct, it will could have a certain destructivenesses on facility, environment, resource, etc. in original area, the destroyed area can well resume the steady state, and it does not influence the residents' life.
WO	The concrete implementation intensity of the old urban area reconstructed.
CC	The old urban area reconstruction of overall cost and expense source.
PI	Dependability of constructing and completion intensity.
EU	It can fully utilize existing resources.

The decision-making model of urban renewal proposals based on AHP

Analytical hierarchy process (AHP) was brought up by an American operational research experts T. L. Saaty in mid 70’s of the 20th century. The fundamental theory is to assess proposal based on objectives, sub objectives, restricted condition and departments, which are leveled hierarchical structural, form a contrast matrix, then use the components of vectors from the biggest feature of judgment matrix and its related feature as the related coefficient, and eventually conclude the priority

of each proposal. AHP is a qualitatively and quantitatively combined, systematically, and hierarchical analyzing method ([3]).

Before data was collected and calculated, a decision-making model must be built up with respecting to a decision-making problem. For the decision-making problem of old town renewal proposal, its model is shown as diagram 1, the meanings of the characters are given in chart 1. The final goal of decision-making model is the highest standard of descriptive problem (it is referred as "the best designed proposal" here). The second level is the decision-making objective level, which includes four aspects: social, economical, environmental, and engineering. These four indexes are composed from different decision-making designs, shown as Figure 1.

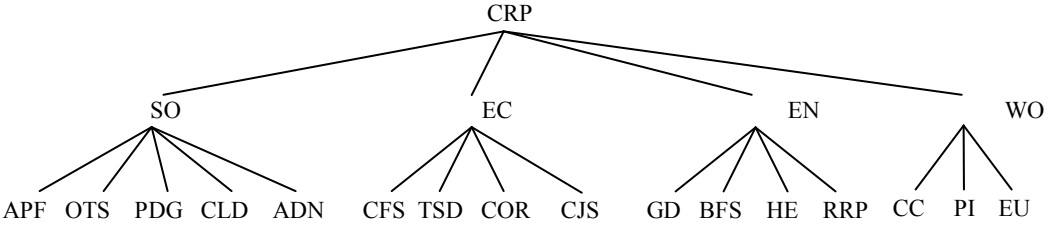

Fig. 1 AHP decision model for producing sustainable urban renewal proposal

A case study of the town renewal proposal based on AHP

As a designed case, this essay brings up three proposals about a town renewal construction. In order to make sure the priority of hierarchal decision-making model of sustainable development objective in the second level, and the relative importance of each distinct designed proposal in the third level, personals participated in old town renewal will accomplish a series of one-to-one comparison. In order to obtain a representative result, we have invited 40 citizens, which include scholars, residents, foreigners, and developers. We separate these citizens into 4 groups with respect to their identities, and assess the three old town renewal proposals mentioned above in the form of groups. While making comparisons between old town renewal proposal and each projects using AHP, assessors must follow the 9-point scale in Table 3 to make judgment. The final grading of the judgment of two elements' importance and every possible advice is based on the combination of observations proceeded in the process of judgment of each group.

Taking an example of a group of scholars, calculate the weight of program priority according to the specific scale and the calculation steps in AHP. Table 3 shows the relative assessment results with respect of four objectives of a group of scholars. Table 4 shows the relatively comparative results among social sub principles. With the same method, we can obtain the relatively comparative results among sub principles of other programs, shown as Table 5. Table 6 is a project hierarchy judgment matrix of public infrastructure setting and utilizing rate. The relative comparative result between each of other designing program hierarchies and project hierarchy can also be calculated. After calculating the comparative data of each designing program hierarchy with respect to program hierarchy, we integrate the weights of objective hierarchy to obtain the comprehensive weights of each designing program at first, and then we calculate the weights of each project. With above calculation, we get an overall assessment of three proposals about old town renewal with respect to a group of scholars. The first proposal is 0.3401, second one is 0.3207, and the third one is 0.3391. With the same method, we can get the assessment of the projects for the other three groups of people, shown as Table 7.

Table 3 Comparisons of objectives

CRP	SO	EC	EN	WO	Weights
SO	1	3	5	7	0.5880
EC	1/3	1	1/2	3	0.1545
EN	1/5	2	1	3	0.1923

SOT	0.0942				0.0554
DSE	0.3248				0.1910
OTP	0.1549				0.0911
RDA	0.0820				0.0482
CFS		0.4262			0.0658
TSD		0.3480			0.0538
COR		0.1322			0.0204
CJS		0.0935			0.0144
GF			0.0742		0.0143
BFS			0.1972		0.0379
HE			0.4569		0.0879
RF			0.2717		0.0522
CC				0.5695	0.0371
IN				0.0974	0.0064
EU				0.3331	0.0217

Table 6 Comparisons of three design schemes

PFU	D1	D2	D3	Weights
D1	1	5	3	0.6267
D2	1/5	1	1/4	0.0936
D3	1/3	4	1	0.2797

$\lambda_{\max} = 3.0858$, C.R. = 0.0739 < 0.10

with respect to PFU

Table 7 The weighted order of four groups with respect to three design schemes

Valuator	First proposal	Second proposal	Third proposal
Scholars	0.3401	0.3207	0.3391
Foreigners	0.3089	0.2764	0.4147
Residents	0.3290	0.3609	0.3099
Developers	0.2664	0.3299	0.4039

In view of the computed results, scholars pay relatively more attention to the first proposal – the content of the first proposal includes pretty good economical efficiency, relatively good sociality, mediocre environmental protection, and relatively poor engineered. Foreigners and developers pay relatively more attention to the third proposal – it includes pretty good sociality, relatively good engineered, mediocre economical efficiency and poor environmental protection. Residents emphasize on the second proposal – it includes pretty good environmental protection, relatively good sociality, and mediocre engineered and poor economical efficiency.

Multi-criteria location problem based on rectilinear norm

Given demand points in R^n, a problem to locate a new facility in R^n is called a single facility location problem. The problem is usually formulated as a minimization problem with an objective function involving distances between the facility and demand points. It is assumed that m demand points $D = \{d_1, d_2, \cdots, d_m\}$, $d_i = (d_i^1, d_i^2, \cdots, d_i^n)^T \in R^n$, $i \in M = \{1, 2, \cdots, m\}$ and rectilinear norm $\|\cdot\|_1$ defined on R^n are given. Let $x = (x^1, x^2, \cdots, x^n)^T \in R^n$ be the location of the facility to be determined. We put $D = \{d_i \mid i \in M\}$. Without loss of generality, it is assumed that $D \not\subset \{(x^1, x^2, \cdots, x^n)^T \in R^n : x^j = x_0\}$ for each $j \in J = \{1, 2, \cdots, n\}$ and any $x_0 \in R$, then our main problem is a multi-criteria location problem formulated as follows

$$(\mathrm{P}) \quad \min_{x \in R^n} f(x) = (\| x - d_1 \|_1, \| x - d_2 \|_1, \cdots, \| x - d_m \|_1)^T. \tag{1}$$

Let $E(D)$ and $QE(D)$ be the set of all efficient solutions of (P) and the set of all quasi-efficient solutions of (P), respectively. By the above definitions, it can be seen that $D \subset E(D) \subset QE(D)$. Our main interest is to find $QE(D)$. In order to characterize quasi-efficient solutions of (P), we also consider a scalarization problem formulated as follows:

$$(\mathrm{P}_\lambda) \quad \min_{x \in R^n} g(x) = \sum_{i=1}^{m} \lambda_i \| x - d_i \|_1, \tag{2}$$

where each λ_i, $i \in M$ is a non-negative weight associated with d_i, and $\lambda = (\lambda_1, \lambda_2, \cdots, \lambda_m)^T \neq 0$.

Theorem 1 ([3]) A point $x_0 \in R^n$ is quasi-efficient solution in (P) if and only if x_0 is optimal solution in (P_λ) for some $\lambda \geq 0$ with $\lambda \neq 0$.

From Theorem 1, $QE(D)$ and $E(D)$ can be expressed as

$$QE(D) = \{x^* \in R^n \mid x^* \in R^n \mid x^* \in S^*(\lambda) \text{ for some } \lambda \geq 0 \text{ with } \lambda \neq 0\}$$

and

$$E(D) = \{x^* \in R^n \mid x^* \in R^n \mid x^* \in S^*(\lambda) \text{ for some } \lambda > 0\},$$

where $S^*(\lambda)$ is the optimal solution set of (P_λ) for some $\lambda > 0$.

Since the objective function of (P_λ) can be rewritten as

$$(P_\lambda) \quad \min_{x \in R^n} g(x) = \sum_{i=1}^{m} \lambda_i \sum_{j=1}^{n} | x^j - d_i^j | = \sum_{j=1}^{n} \sum_{i=1}^{m} \lambda_i | x^j - d_i^j | . \tag{3}$$

Namely, $x^* = (x^{1*}, x^{2*}, \cdots, x^{n*})^T \in S^*(\lambda)$ if and only if each x^{j*}, $j \in J$ is an optimal solution of the following one-dimensional problem:

$$(P_j) \quad \min_{x \in R} g_j(x) = \sum_{i=1}^{m} \lambda_i | x^j - d_i^j |, \tag{4}$$

where $j \in J$. For these one-dimensional problems, we can be to find all quasi-efficient solutions by algorithm in [5].

When $n = 2$, all unions of efficient solutions of Problem (P) are given in [6], all unions of junior efficient solutions of Problem (P) are given in [7]. Solutions of Problem (P_λ) could be calculated using the algorithm mentioned in [5].

Next, based on the properties of efficient solutions of multi-purpose allocation problems mentioned in [7], we discuss the scalarization algorithm of multi-purpose allocation problems.

For each $j \in \{1, 2, \cdots, n\}$, let $d^j_{[[1]]}, d^j_{[[2]]}, \cdots, d^j_{[[m_j]]}$ be all distinct real numbers among $d_1^j, d_2^j, \cdots, d_m^j$ such that $d^j_{[[1]]} < d^j_{[[2]]} < \cdots < d^j_{[[m_j]]}$, and we put

$$F^j_{2k-1} = \{d^j_{[[m_j]]}\}, \quad k = 1, 2, \cdots, m_j \tag{5}$$

and

$$F^j_{2k} = [d^j_{[[k]]}, d^j_{[[k+1]]}], \quad k = 1, 2, \cdots, m_j - 1. \tag{6}$$

For each $k_j \in \{1, 2, \cdots, 2m_j - 1\}$, $j \in J$, $F^1_{k_1} \times F^2_{k_2} \times \cdots \times F^n_{k_n}$ is called a box. Moreover, if k numbers are even among $k_1, k_2, \cdots, k_n$, then $F^1_{k_1} \times F^2_{k_2} \times \cdots \times F^n_{k_n}$ is called k-dimensional box.

For any fixed $\lambda \geq 0$ with $\lambda \neq 0$,

$$S^*(\lambda) = (F^1_{k_1} \cup F^1_{k_2} \cup \cdots \cup F^1_{k_n}\} \times \{F^2_{k_1} \cup F^2_{k_2} \cup \cdots \cup F^2_{k_n}\} \times \cdots \times \{F^n_{k_1} \cup F^n_{k_2} \cup \cdots \cup F^n_{k_n})$$

for some k_j, $k_j' \in \{1, 2, \cdots, 2m_j - 1\}$ with $k_j \leq k_j'$, $j \in J$. Therefore, $QE(D)$ is the union of some boxes. The union of all one-dimensional boxes in $QE(D)$ is called the frame of $QE(D)$.

For $a = (a^1, a^2, \cdots, a^n)^T \in \prod_{j=1}^{n} \{1, 2, \cdots, 2m_j - 1\}$, we put

$$F(a) = \prod_{j=1}^{n} F^j_{a^j}. \tag{7}$$

Next, for $a \in A = (\prod_{j=1}^{n} \{1, 2, \cdots, 2m_j - 1\}) \setminus (\prod_{j=1}^{n} \{2k - 1 \mid k \in \{1, 2, \cdots, m_j\}\})$, we check λ such that $F(a)$ is a set of all optimal solutions of (P_λ) exists or not. If such λ exists, the $\forall x \in F(a)$ is a solutions of (P_λ).

For $F(a)$, $a \in A$, we assume

$$J_2(a) = \{j \in \{1, 2, \cdots, n\} \mid a^j \text{ is even}\} \neq \varnothing,$$

$F(a)$ is called $|J_2(a)|$-dimensional box. $|J_2(a)|$ said the number of elements. For $k \in \{1,2,\cdots,n\}$, we assume

$$A_k = \{a \in A \,|\, |J_2(a)| = k\} \neq \varnothing,$$

$F(a)$ is called $k-$dimensional box.

The algorithm of solving $E(D)$

Step 1 Set $T^* = \varnothing$ and $k = n$.

Step 2 For each $F(a) \not\subset T^*$, $a \in A$, check $\lambda > 0$ such that $F(a)$ is set of all optimal solutions of Problem (P_λ) exists or not. If such λ exists, we put $T^* = T^* \cup F(a)$.

Step 3 If $k \neq 1$, $k = k-1$, go to Step 2, otherwise, then stop. The $E(D) = T^*$ is set of all efficient solutions of Problem (P).

Analysis on results obtained based on AHP using location problem

From the calculation of the fourth part, we know that the assessment results of the three town renewal proposals that scholars, foreigners, residents and developers separately assess are not unified, and this causes certain confusion to the final decision makers because taking each proposal will disappoint those who disagree with such proposal. Subsequently, we need to find such method that can generate a comprehensive evaluation of these three assessment results in order to obtain a final proposal that more people will approve. We try to solve this problem using the method that solves the allocation problem mentioned above.

Let $d_i = (d_i^1, d_i^2, d_i^3)^T$, $i = 1,2,3,4$ be a priority weight vector of i-group. From Table 7, we get $d_1 = (0.3401, 0.3207, 0.3391)^T$, $d_2 = (0.3089, 0.2764, 0.4147)^T$, $d_3 = (0.3290, 0.3609, 0.3099)^T$ and $d_4 = (0.2664, 0.3299, 0.4039)^T$. Let $x = (x^1, x^2, x^3)^T$, x^1, x^2 and x^3 be a final evaluation results of the first proposal, the second proposal and the third proposal, respectively.

From Problem (P), we have

$$(\mathrm{P}) \quad \min_{x \in R^4} f(x) = (\| x - d_1 \|_1, \| x - d_2 \|_1, \| x - d_3 \|_1, | x - d_4 \|_1)^T. \tag{8}$$

Since the objective function of (P_λ), $g_j(x)$ can be rewritten as

$$(\mathrm{P}_j) \quad \min_{x \in R} g_j(x) = \sum_{i=1}^{4} \lambda_i | x^j - d_i^j |. \tag{9}$$

According to the calculation steps in part 5, we proceed to further calculation and analysis of the data in Table 7 that reflects the assessment weights that scholars, foreigners, residents and developers weight about the three proposals.

Let $d_1 = (0.3401, 0.3207, 0.3391)^T$, $d_2 = (0.3089, 0.2764, 0.4147)^T$, $d_3 = (0.3290, 0.3609, 0.3099)^T$ and $d_4 = (0.2664, 0.3299, 0.4039)^T$. From formula (5) and formula (7), we have

$F_1^1 = \{0.2664\}$, $F_2^1 = [0.2664, 0.3089]$, $F_3^1 = \{0.3089\}$, $F_4^1 = [0.3089, 0.329]$, $F_5^1 = \{0.329\}$, $F_6^1 = [0.329, 0.3401]$, $F_7^1 = \{0.3401\}$, $F_1^2 = \{0.2764\}$, $F_2^2 = [0.2764, 0.3207]$, $F_3^2 = \{0.3207\}$, $F_4^2 = [0.3207, 0.3299]$, $F_5^2 = \{0.3299\}$, $F_6^2 = [0.3299, 0.3609]$, $F_7^2 = \{0.3609\}$, $F_1^3 = \{0.3099\}$, $F_2^3 = [0.3099, 0.3391]$, $F_3^3 = \{0.3391\}$, $F_4^3 = [0.3391, 0.4039]$, $F_5^3 = \{0.4039\}$, $F_6^3 = [0.4039, 0.4147]$, $F_7^3 = \{0.4147\}$.

Then

$A_1 = (\{1,3,5,7\} \times \{1,3,5,7\} \times \{2,4,6\}) \cup (\{1,3,5,7\} \times \{2,4,6\} \times \{1,3,5,7\}) \cup (\{1,3,5\} \times \{2,4,6\}$,

$A_2 = (\{2,4,6\} \times \{1,3,5,7\} \times \{1,3,5,7\}) \cup (\{2,4,6\} \times \{1,3,5,7\} \times \{2,4,6\}) \cup (\{2,4,6\} \times \{2,4,6\}$
$\times \{1,3,5,7\}) \cup (\{2,4,6\} \times \{2,4,6\} \times \{2,4,6\})$.

We could get the solutions of problem (P_λ) under four situations from above calculations, which is such multi-purpose problem has solutions under the following four situations:

(ⅰ) When $a=(2,5,5)^T$, let $\lambda=(1,1,1,3)^T$. In this situation, developers' opinion is the most important, their satisfaction is $[0.2664,0.3089]\times\{0.3299\}\times\{0.4039\}$, which tells that developers consider the third proposal as the best one.

(ⅱ) When $a=(6,3,3)^T$, let $\lambda=(3,1,1,1)^T$. In this situation, scholars' opinion is the most important, and their satisfaction to the third proposal is $[0.329,0.3401]\times\{0.3207\}\times\{0.3391\}$, which tells that scholars think both the first proposal and the third one are fine.

(ⅲ) When $a=(3,2,6)^T$, let $\lambda=(1,3,1,1)^T$. In this situation, foreigners' opinion is the most important, and their satisfaction to these three proposals is $\{0.3089\}\times[0.2764,0.3207]\times[0.4039,0.4147]$, which tells that foreigners consider the third proposal as the best one.

(ⅳ) When $a=(5,6,2)^T$, let $\lambda=(1,1,3,1)^T$. In this situation, residents' opinion is the most important, and their satisfaction about these three proposals is $\{0.329\}\times[0.3299,0.3609]\times[0.3099,0.3391]$, that is residents think both the second and the third proposal are fine.

Consolidated above four situations, scholars, foreigners, residents and developers all choose the third proposal, which concludes the third proposal is relatively outstanding and it has the most public opinion.

Conclusion

This essay focuses on making the decision-making process of such problem to be easier by using AHP. Although AHP is neither the best nor the only solution for all daily decision problems, AHP is an efficient tool for old town renewal proposal assessment. There exist disadvantages when assessing old town renewal proposal merely depends on AHP. From the analyzing results, it is efficient to assess old town renewal proposal when these two methods are combined because this reduces people's subjectivity and makes decisions more rational.

E-mail: zbj2013ch@163.com

Keywords: AHP; MCDM; House plan; Proposal assessment

Abstract. In this paper, we suggest and analyze a new support system for easy decision-making on housing planning. Using this, user's can analyze their preferences by themselves individually and can select optimal alternatives. The purpose of this paper is to propose a rational decision-making system in housing planning based on the ASP (Analytic Hierarchy Process). Then, we show how standard evaluation can be decided on this system. In this paper, evaluation and election of the room arrangements is based on the information data came from users.

Introduction

House plan is a complex process that has been commonly adopted to meet various market supply. In this case, even cost a lot of money also can not obtain favorite house. Building a favorite house is every one's dream. In view of it, it is necessary to have a tool to assist the users in working out the most house plan. In order to ensure that the final proposal is convincing, a more systematic and sophisticated method to make the tradeoff decisions is required. Therefore, this paper encourages the use of analytic hierarchy process (AHP) in dealing with this challenge. The basic problem of decision-making is how to choose best one in a set of competing alternatives that are evaluated under conflicting criteria. The method of Analytic Hierarchy Process (AHP) provides us with a comprehensive framework for solving such problem. We are reported by using the AHP to evaluate housing planning by qualitative elements such as several kinds of construction methods, room arrangement, and designs. Based on this research on room arrangements particularly, we observe a mathematical approach for decision-making in housing planning problems in this paper.

What is AHP?

Before discussing AHP, it is necessary to know what multi-criteria decision making (MCDM) method is. MCDM methods are valuable in reaching important decisions that cannot be determined straightforwardly. Nowadays, there are numbers of MCDM methods available for selection. As mentioned, AHP is one of the MCDM methods. Saaty (1980) developed AHP which models a hierarchical decision problem framework that consists of multiple levels of criteria having unidirectional relationships. AHP works with such hierarchy that can combine both subjective (intangible) and objective (tangible) criteria. AHP is a reliable tool to facilitate systematic and logic stated al decision making processes, and determine the significance of a set of criteria and sub-criteria. It is widely applied to construction fields such as resources allocation, project design, planning for urban development, maintenance management, policy evaluation, etc. AHP is composed of seven major steps (see [4]):

(1) To identify the decision problem—The decision problem has to be in the topmost level of a hierarchy that is broken down into different levels in which the final level is usually the scenarios or alternatives to be selected;

(2) To ascertain that the problem can be solved by AHP—AHP is suitable for the decision problem that can be turned into a hierarchical decision model;

(3) To structure the decision problem—A hierarchy structure formed for the decision problem consists of several levels;

(4) To determine the raters—AHP solicits expert's judgment and therefore, only experts are eligible to be the raters who are responsible for making the decision;

(5) To collect data from the raters—AHP determines the relative priorities of different criteria in every level of the hierarchy by employing a pairwise comparison. During the process, each expert is required to make judgments on their relative importance in relation to the element at the higher level with reference to a 9-point scale;

(6) To calculate the priority weights of each criterion—Each decomposed level with respect to a higher level forms a Matrix;

(7) To measure the consistency ratio (C.R.)—This practice is to ascertain that the experts are consistent in rating the relative importance of the criteria.

Housing plan model by AHP

There are the following three principles when we use the AHP method in problem solving. They are principles of decomposition, comparative judgments, and synthesis of priorities. The decomposition principle requires structuring the hierarchy to capture the basic elements of the problem. An effective way to do this is first to work downward from the focus in the top level to criteria bearing on focus in the second level, followed by subcriteria in third level, and so on, from the more general to the more particular and definite. The bottom level elements are alternatives. The structure of a hierarchy is given by Figure 1.

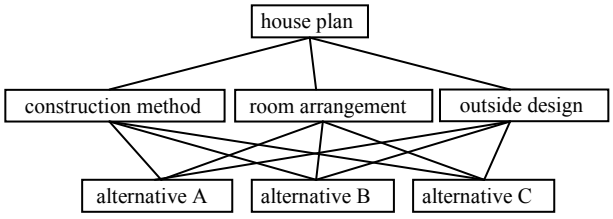

Fig. 1 Structure of a hierarchy

We propose a systematical procedure to select optimal solution for a user who wants to build own house. Form view of mathematical programming, we introduce a certain type of multi-criteria evaluation associated with a house plan by the following formula

$$\begin{cases} \text{minimize } (f_1, f_2, f_3) \\ \text{subject to } (v_1, v_2, v_3) \end{cases}. \tag{1}$$

The symbols shown in the formula (1) are defined, as

f_1= construction method; f_2= room arrangement; f_3= outside design;

v_1=economical conditions; v_2= site-conditions; v_3=others.

This research can give a comprehensive evaluation for user's preference with concrete values. At first, a user's plan is quantified by certain evaluations based on each criterion, and then its comprehensive evaluation can be calculated by their weighted sum. If the comprehensive evaluation is not satisfactory for the user, quantifications will be modified by perturbing evaluation values. This evaluation method with multi-criteria can be written as follows.

Before building the house, users have to select an optimal construction type from some alternatives of construction styles, such as wooden, building area, and so on. Moreover, outside design is also important for the evaluation as another preference for users. In comparison with these two criteria, room arrangement seems to more complex and most important for users.

In this paper, we assume that the land for house is sufficiently suitable and wide, and that it is satisfactory for general conditions of the single house. Furthermore, we assume that a user is satisfied with this land.

Comprehensive evaluation for the house of room arrangements

Calculation of the weight. It can be judged by AHP which item is most important among the three criteria (see [1]). So it is necessary to judge the weight of each item by the information came from the users. It is interpreted as the factor with highest weight being good. Moreover, it turns out that users are thinking which evaluation item as most important by the value of weight. Saaty [1] proposed the AHP absolute measurement method and AHP relative measurement method as algorithm. The alternatives may be evaluated by paired comparisons (relative measurement). Weights of the single house are given according to the following Figure 2.

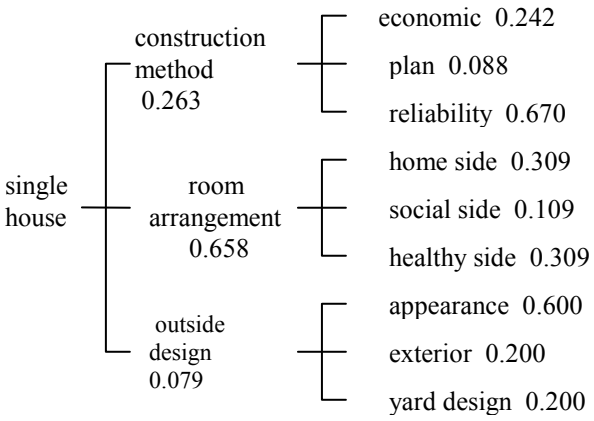

Fig. 2 Weights of the single house

Maximization of utility problem on the floor space. For users as a family, if the area of a site of a site is fixed, there is a problem how the floor space of room arrangement should be chosen. In the same situation, each user may not choose the same plan. In this paper, based on the information came from many users, the utility problem function on selection of the floor space is expressed as follows:

$$U = U(\sum_{i=1}^{n} \omega_i u_i(x_i)), \tag{2}$$

where ω_i is weight of selection of floor space x_i, and $u_i(x_i)$ is evaluation function about selection of floor space x_i. The width of each room is not only restricted to the width of the next room, but also restricted to the floor space of a house. For a user, the biggest concern is to select floor space to the expected maximum utility. We can construct the following function for the optimal floor space which can be determined according to its utility:

$$\begin{cases} \text{minimize} \ \sum_{i=1}^{n} \omega_i u_i(x_i) \\ \text{subject to} \ \sum_{i=1}^{n} x_i \le L,\ x_i \in S_i,\ i = 1, \cdots, n \end{cases}, \tag{3}$$

where L is the floor space of a house, and it is related to a loan, and S_i (i=1,…,n) is a set of relative to the floor space of each room. Then, we introduce the method of asking for the utility function $u_i(x_i)$. To calculate the coefficient of an utility function by using the certain degree of each floor area. The algorithm for finding the function $u_i(x_i)$ which use Lagrange interpolation polynomial is proposed.

Maximization utility problem is expressed definitely as follows:

$$\begin{cases} \text{minimize} \ \sum_{i=1}^{n} \omega_i (a x_i^5 + b x_i^4 + c x_i^3 + d x_i^2 + e x_i + f) \\ \text{subject to} \ \sum_{i=1}^{n} x_i \le L,\ x_i \in S_i,\ i = 1, \cdots, n \end{cases}. \tag{4}$$

Example

First the weighs of each factor are calculated. The degrees of each factor are calculated possibly if the weights of each factor are known. A degree shows which factor a user thinks as most important. For example, calculate a degree of a kitchen room according to the following Table 1. There values show that the user thinks kitchen room area 9 m^2 is the most important. Next the function $u_i(x_i)$ is approximated by using the Lagrange interpolation polynomial by the polynomial which passes though points $\{x_i, f_i\}$. Here x_i and f_i are floor space and degree, respectively. By Table 1, $\{x_1, x_2, x_3, x_4, x_5\}=\{6, 7.5, 9, 10.5, 12\}$ and $\{f_1, f_2, f_3, f_4, f_5\}=\{0.1, 0.7, 1.0, 0.7, 0.4\}$ are floor space and degree of a kitchen room, respectively. Then we can obtain following utility function $u(x)$ of a kitchen room by the upper algorithm:

$$u(x) = 0.01x^4 - 0.26x^3 + 3.25x^2 - 17.12x + 32.20 .$$

Therefore, we can obtain the others coefficients by the same method as follows. See the Table 2.

Table 1 Degree of kitchen room

CRP	6 m^2	7.5 m^2	9 m^2	10.5 m^2	12 m^2	Weights	Degree
6 m^2	1	1/5	1/7	1/5	1/3	0.043	0.1
7.5 m^2	5	1	1/3	1	5	0.244	0.7

Comprehensive evaluation system of room arrangement. After the area of each room is decided, the comprehensive evaluation system of room arrangement will be considered. In this paper, a ten-point method is used to evaluate room arrangement. The comprehensive evaluation system is proposed by the following Table 3. The weights of a framework are calculated in Subsection of calculation of the weight. The user can obtain the optimal solution easily in an objective framework by using qualitative data, which expresses an evaluation result.

Table 3. Comprehensive evaluation system

	Item	An evaluating point	Weight	Result
homely side	number width functionality arrangement receipt	1—10	0.066 0.118 0.419 0.111 0.286	=6—10 (good) =4—6 (good in general) =1.5—4 (not good) =1—1.5 (quite bad)

healthy side	sanitary sunshine ventilation safety	1—10	0.054 0.306 0.154 0.486	

Algorithm

House design software can create a floor plan quickly, and we can look at a floor plan from many angles, but it cannot judge the floor plan scientifically. In this paper, users not only plan a wish house by using this software, but also express his preference quantitatively, and evaluate it scientifically. Specifically, the automatic generation algorithm of the house plan arrangement was proposed follows:

Step 1 A user's hope is arranged.

Step 2 After deciding the total floor space, the maximum floor area of using is calculated. If restriction conditions are satisfied, it will go to next step, otherwise, it returns to step1 and the area of each room is corrected.

Step 3 The wish house in step1 is designed by using house design software.

Step 4 The house as an image is evaluated. If it satisfies the user's preference sufficiently, the total cost will be calculated and a house maker will be chosen. Otherwise, it returns to step1 and improved unreasonable designs.

Conclusion

In this paper, a house planning system is established that can determine several kinds user's hope in short time based on a rational decision-making system by using AHP method.

It is necessary to determine algorithm which can connect research in this paper with house design software by using the various decision-making technique containing AHP method.

Keywords: rotation symmetric H Boolean functions; e-derivative; algebraic immunity; correlation immunity; annihilators

Abstract. Boolean functions with a variety of secure cipher properties are the key factors to design cryptosystem with the ability to resist multiple cipher attacks and good safety performance. In this paper, using the derivative of the Boolean functions and the e-derivative defined by ourselves as the main research tools, we study algebraic immunity, correlation immunity and other cryptographic properties of the quadratic rotation symmetric Boolean functions. We determine the quadratic rotation symmetric Boolean functions which are H Boolean functions, and the range of weight distribution of the quadratic rotation symmetry H Boolean functions. Besides, we get the compatibility among propagation, balance, correlation immunity and algebraic immunity of the quadratic rotation symmetry H Boolean functions, and also focus on the relationship of balance, correlation immunity and dimension. Furthermore, we check the existence of the cubic rotation symmetry H Boolean functions, and obtain the relationship between existence and dimension of the cubic rotation symmetry H Boolean functions. Moreover, we obtain a more convenient method for solving annihilator. Such researches are important in cryptographic primitive designs, and have significance and role in the theory and application range of cryptosystems.

Introduction

Boolean functions are compatible with a variety of cryptographic properties is always an important problem in studying cryptography, which is related to the cryptosystem' ability to resist a variety of cipher attacks. Rotation symmetric Boolean functions (RSBFs) are a kind of functions with special algebraic structure, and having been well application in cryptography. In 1999, RSBFs were proposed by Pieprzyk and Qu to apply in some cipher algorithms, such as MD4, MD5 and fast implementation of HAVAL [1]. RSBFs are paid wide attention in cryptography academia when it was been proposed, and some researchers always study them. In the recent year, there have many valuable results [4~15] about the study of algebraic immunity and other cryptographic properties of RSBFs. There are a lot of research methods for the study of RSBFs such as recursive definition, cascade calculations and orbit division [7~11]. The methods above need to calculate step by step, and it is complicated in calculation. In this paper, we use the derivative [16~18] and the custom e-derivative as the main research tools, and study the problems of rotation symmetric Boolean functions and rotation symmetric H Boolean functions, such as the structure, the relationship between weight and dimension, balance, correlation immunity, the relationship between propagation and algebraic degree, algebraic immunity and solving methods of annihilator. We get some valuable conclusions.

Preliminaries

The Boolean functions of cryptographic are defined on Galois field $GF(2)$. In this paper, we discuss cryptographic properties of rotation symmetric H Boolean functions on $GF(2)$.

Now the e-derivative is defined here. The readers may refer to [19~21] for more information on e-derivative.

Definition 1[19~21]**.** The e-derivative (e-partial derivative) of *n*-dimensional Boolean functions $f(x_1,x_2,\cdots,x_n)$ for *r* variables $x_{i1},x_{i2},\cdots,x_{ir}$ $(i,r,i_1,i_2,...,i_r\in[1,n])$ is defined as

$$ef(x)/e(x_{i1},x_{i2},\cdots,x_{ir})=f(x_1,x_2,\cdots,x_{i1},x_{i2},\cdots,x_{ir},\cdots,x_n)f(x_1,x_2,\cdots,1+x_{i1},1+x_{i2},\cdots,1+x_{ir},\cdots,x_n). \quad (1)$$

If $r=1$, (1) turns into the e-derivative of $f(x)=f(x_1,x_2,\cdots,x_n)$ for a single variable, which is denoted by $ef(x)/ex_i$ $(i=1,2,\cdots,n)$. As a result, the simplified form below can be easily derived.

$$ef(x)/ex_i=f(x_1,x_2,\cdots,x_{i-1},1,x_{i+1},\cdots,x_n)f(x_1,x_2,\cdots,x_{i-1},0,x_{i+1},\cdots,x_n)\ (i=1,2,\cdots,n). \quad (2)$$

According to the definition of e-derivative and derivative, we can get Lemmas 1&2 easily.

Lemma 1. The sufficient and necessary condition of *n*-dimensional Boolean functions $f(x)$ to satisfy the *k*-degree propagation criterion is: for all $r=1,2,\cdots,k$, there is

$$w_t(\partial f(x)/\partial(x_{i1},x_{i2},\cdots,x_{ir}))=2^{n-1}\ (i_1,i_2,\cdots,i_r\in[1,n]). \quad (3)$$

Lemma 2. The (4) that follow describe the relationship of *n*-dimensional Boolean functions.

$$f(x)=f(x)\partial f(x)/\partial(x_{i1},x_{i2},\cdots,x_{ir})+ef(x)/e(x_{i1},x_{i2},\cdots,x_{ir})\ (i_1,i_2,\cdots,i_r\in[1,n]). \quad (4)$$

We will involve RSBFs with degree $k(k\geq 3)$, so the definition of *k*-degree BF is given below.

Definition 3. Let $n\in I_+$, for any $x=(x_1,x_2,\cdots,x_n)\in GF(2)^n$, define $\rho_n^k(x)=(\rho_n^k(x_1),\rho_n^k(x_2),\cdots,\rho_n^k(x_n))$ $(k\in I_+,0\leq k\leq n-1)$, among them $\rho_n^k(x_i)=\begin{cases}x_{i+k}, & i+k\leq n\\ x_{i+k-n}, & i+k>n\end{cases}$. If for any $x=(x_1,x_2,\cdots,x_n)\in GF(2)^n$ and $f(\rho_n^k(x))=f(x)$ $(0\leq k\leq n-1)$, $f(x)$ is called a RSBF.

Definition 4. If *n*-dimensional Boolean functions $f(x)$,which have if and only if *k*-degree $(k\in\{1,2,\cdots,n\})$ terms, $f(x)$ is called a pure *k*-degree Boolean function. And if $f(x)$ has if and only if different *k*-degree terms whose total number is $\binom{n}{k}$, $f(x)$ is called completely pure *k*-degree Boolean function, denoted by $f_0^k(x)$ $(k\in\{1,2,\cdots,n\})$. i.e. A Boolean function $f(x)$ is a completely pure *k*-degrees Boolean function,iff $f(x)$ is the sum of different *k*-degree terms which has $\binom{n}{k}$.

The basic properties of the quadratic rotation symmetric H Boolean functions

Quadratic rotation symmetry H Boolean functions have propagation, we need to study other cryptographic properties and basic properties of this functions.

Theorem 1. 1) The sum of two RSBFs $f_1(x)$ and $f_2(x)$, $f(x)=f_1(x)+f_2(x)$ are still RSBFs [22].

2) All *n*-dimensional $(n\geq 3)$ completely pure *k*-degree Boolean functions $f_0^k(x)$ $(k=1,2,\cdots,n)$ are RSBFs. In Boolean functions that are consist entirely of *k*-degree terms, only completely pure *k*-degree Boolean functions $f_0^k(x)$ are RSBFs**.**

3) Quadratic RSBFs $f_1(x)=f_0^2(x)$ and $f_2(x)=f_0^1(x)+f_0^2(x)$ are RS H Boolean functions.

Proof. 1) The readers may refer to [22].

2) For any rotation transformation $\rho_n^r(x)$ $(0\leq r\leq n-1)$, without loss of generality, we only prove $r+i=n$ $(i=1,2,\cdots,n)$. Then $\begin{pmatrix}x_1,x_2,\cdots,x_{i-1},x_i,x_{i+1},x_{i+2},\cdots,x_n\\ x_{r+1},x_{r+2},\cdots,x_{n-1},x_n,x_1,x_2,\cdots,x_r\end{pmatrix}$ describe the *n*-order replacement of $\rho_n^r(x)$ on the components of $x=(x_1,x_2,\cdots,x_n)$.

In $\{x_1,x_2,\cdots,x_{i-1},x_i,x_{i+1},x_{i+2},\cdots,x_n\}$, we take the product of the *k*-th components as one term, total $\binom{n}{k}$ terms, $f_0^k(x)$ is composed by the sum of all $\binom{n}{k}$ terms. In $\{x_{r+1},x_{r+2},\cdots,x_{n-1},x_n,x_1,x_2,\cdots,x_r\}$, we take the product of the *k*-th components as one terms, total $\binom{n}{k}$ terms, $f_0^k(\rho_n^r(x))$ is composed by the sum of all $\binom{n}{k}$ terms. So $f_0^k(\rho_n^r(x))=f_0^k(x)$, i.e. $f_0^k(x)$ is a RSBF.

After removing some of the terms in $f_0^k(x)$, $f_0^k(x)$ must not be RSBFs. Without loss of generality, suppose $f(x)=f_0^k(x)+x_{i1}x_{i2}\cdots x_{ik}$.

Since for $0\le r\le n-1$, there are $f_0^k(\rho_n^r(x))=f_0^k(x)$.

Then for all $i=1,2,\cdots,n$, there must be $df_0^k(\rho_n^r(x))/dx_i=df_0^k(x)/dx_i$.

Suppose $\rho_n^r(x_{i1}x_{i2}\cdots x_{ik})=x_{s1}x_{s2}\cdots x_{sk}$, by the 1) of the theorem 1, we can know

$f(\rho_n^r(x))=f_0^k(\rho_n^r(x))+\rho_n^r(x_{i1}x_{i2}\cdots x_{ik})=f_0^k(x)+x_{s1}x_{s2}\cdots x_{sk}$.

So $df(\rho_n^r(x))/dx_{sk}=df_0^k(x)/dx_{sk}+x_{s1}x_{s2}\cdots x_{s(k-1)}\neq df_0^k(x)/dx_{sk}$.

It is contradicted with $df_0^k(\rho_n^r(x))/dx_i=df_0^k(x)/dx_i$.Therefore, $f(x)$ is not a RSBF.

3) Since for all $i=1,2,\cdots,n$, there are

$$\begin{cases} w_t(df_1(x)/dx_i)=w_t(df_0^2(x)/dx_i)=w_t(x_1+x_2+\ldots+x_{i-1}+x_{i+1}+x_{i+2}+\ldots+x_n)=2^{n-1} \\ w_t(df_2(x)/dx_i)=w_t(1+x_1+x_2+\ldots+x_{i-1}+x_{i+1}+x_{i+2}+\ldots+x_n)=2^{n-1} \end{cases}.$$

By Lemma 1,we can know that $f_1(x)=f_0^2(x)$ and $f_2(x)=f_0^1(x)+f_0^2(x)$ are H Boolean functions.

Remark 1: Known by the 3) of Theorem 1, $f_1(x)=f_0^2(x)$ and $f_2(x)=f_0^1(x)+f_0^2(x)$ are RS H Boolean functions. But in RSBFs, there may have more than quadratic H Boolean functions. Following we discuss this issue in Theorem 2&3.

Theorem 2. Suppose variables are $x'=(x_2,x_3,\cdots,x_n)$ of $f_{1,n-1}(x')$ and $f_{2,n-1}(x')$. $f_{1,n-1}(x')$ is $f_0^2(x')$ with $n-1$ -dimensional, $f_{2,n-1}(x')$ is $f_0^1(x')+f_0^2(x')$ with $n-1$ -dimensional, $f_{1,n}(x)$ and $f_{2,n}(x)$ are $f_1(x)$ and $f_2(x)$ with *n*-dimensional respectively. Then

1)

$$\begin{cases} f_{1,n}(x)=(1+x_1)f_{1,n-1}(x')+x_1f_{2,n-1}(x') \\ f_{2,n}(x)=(1+x_1)f_{2,n-1}(x')+x_1(1+f_{1,n-1}(x')) \end{cases}. \tag{5}$$

2) In RSBFs, there exist balanced quadratic RS H Boolean functions.

Proof.

1) $f_{1,n}(x)=f_{1,n-1}(x')+x_1\sum_{i=2}^{n}x_i=f_{1,n-1}(x')+x_1(f_{1,n-1}(x')+f_{0,n-1}^1(x')+f_{1,n-1}(x'))=(1+x_1)f_{1,n-1}(x')+x_1f_{2,n-1}(x')$.

$f_{2,n}(x)=f_{0,n}^1(x)+f_{1,n}(x')=f_{0,n}^1(x)+f_{1,n-1}(x')+x_1(x_2+x_3+\cdots+x_n)=x_1+f_{2,n-1}(x')+x_1\sum_{i=2}^{n}x_i$.

$=x_1+f_{2,n-1}(x')+x_1(f_{2,n-1}(x')+f_{1,n-1}(x'))=(1+x_1)f_{2,n-1}(x')+x_1(1+f_{1,n-1}(x'))$

2) By (5), we have

$$w_t(f_{1,n}(x))=w_t((1+x_1)f_{1,n-1}(x'))+w_t(x_1f_{2,n-1}(x')) \text{ and } w_t(f_{2,n}(x))=w_t((1+x_1)f_{2,n-1}(x'))+w_t(x_1f_{1,n-1}(x')) \tag{6}$$

and

$$w_t(f_{1,3}(x))=2^{3-1} \text{ and } w_t(f_{2,3}(x))=2^{3-1}+2^{3-2}. \tag{7}$$

By (6) and (7), We can be deduce these:

$$w_t(f_{1,n}(x))=2^{n-1} \text{ When } n=2r+3\ (r=0,1,2,\cdots);\quad w_t(f_{2,n}(x))=2^{n-1} \text{ When } n=2r+5\ (r=0,1,2,\cdots). \tag{8}$$

Known by (8), there exist balanced RS H Boolean functions.

Corollary 1. $2^{n-2}<w_t(f_i(x))\le 2^{n-1}+2^{n-2}\ (i=1,2)$.

Theorem 3. In completely pure cubic RSBFs $f_0^3(x)$, there exist H Boolean functions [22].

Example 1. For $f_{0,8}^3(x)$, there are

$$\begin{cases} w_t(df_{0,8}^3(x)/dx_1)=2w_t(f_{0,7}^2(x))=2^{8-1}=128 \\ w_t(df_{0,8}^3(x)/dx_i)=2^{8-1}=128 \end{cases} (i=1,2,\cdots,8). \tag{9}$$

Knowing by Lemma 1 and (9), $f_{0,8}^3(x)$ is a rotation symmetric H Boolean function.

Remark 2. Known by Theorem 3, it is difficult to find whether have H Boolean functions in $f_0^3(x)$ through observing directly wihtout derivative. Even if we want to study them,it is also difficult to prove directly. Derivative plays an irreplaceable role in the discovery and proof of Theorem 3.

Because $f(\rho_n^k(x)) = f(x)$ $(0 \le k \le n-1)$, there are $df(\rho_n^k(x))/dx_i = df(x)/dx_i$, $ef(\rho_n^k(x))/ex_i = ef(x)/ex_i$, $(i = 1,2,\cdots,n)$. By Lemma 1&2, it is obvious to deduce Theorem 4. So it is easy to get Theorem 4 without proof.

Theorem 4. The necessary and sufficient conditions of RSBFs $f(x)$ are RS balanced H Boolean functions, are that: $w_t(df(\rho_n^k(x))/dx_i) = 2^{n-1}$ *and* $w_t(ef(\rho_n^k(x))/ex_i) = 2^{n-2}$ $(i = 1,2,\cdots,n)$.

Correlation immunity of quadratic rotation symmetric H Boolean functions

The quadratic RS H Boolean functions have propagation, many quadratic rotation symmetric H Boolean functions have balance. Whether the quadratic rotation symmetric H Boolean functions are not compatible with the correlation immunity,is the ability to resist correlation attack. We discuss the correlation immunity of the quadratic RS H Boolean functions in this section.

Theorem 5. 1) When $n = 4r+3$ $(r = 0,1,2,\cdots)$, $f_2(x) = f_0^1(x) + f_0^2(x)$ are correlation immune functions.

2) When $n = 4r+5$ $(r = 0,1,2,\cdots)$, $f_1(x) = f_0^2(x)$ are correlation immune functions.

Proof. 1) Solve the derivative of $f_2(x)$, we get

$$\partial f_2(x)/\partial(x_1,x_2,\cdots,x_n) = f_2(x) + f_2(1+x) = f_0^1(x) + f_0^1(1+x) + f_0^2(x) + f_0^2(1+x). \quad (10)$$

Because of $n = 4r+3$ $(r = 0,1,2,\cdots)$, so $f_0^1(x) + f_0^1(1+x) = \sum_{i=1}^{n} 1 = 1$ and

$$f_0^2(x) + f_0^2(1+x) = \sum_{i=1}^{n}\sum_{j=1}^{n-1} x_i + \sum_{i=1}^{s} 1 \ (s = 2^{-1}n(n-1)). \quad (11)$$

When $n = 4r+3$ $(r = 0,1,2,\cdots)$, $n-1 \equiv 0 \bmod 2$. While for $s = (4r+3)(2r+1)$, there is $s \equiv 1 \bmod 2$. Take the above formula into (11), we have $f_0^2(x) + f_0^2(1+x) = 1$.

Take $f_0^1(x) + f_0^1(1+x) = \sum_{i=1}^{n} 1 = 1$ and $f_0^2(x) + f_0^2(1+x) = 1$ into (10), we have $\partial f_2(x)/\partial(x_1,x_2,\cdots,x_n) = 0$. Therefore, we can know that for all $i = 1,2,\cdots,n$, there is $w_t(f_2(x) \mid x_i = 0) = w_t(f_2(x) \mid x_i = 1) = 2^{-1}w_t(f_2(x))$. So we can know that, $f_2(x)$ are correlation immune functions when $n = 4r+3$ $(r = 0,1,2,\cdots)$.

When $f_2(x)$ are correlation immune functions of order 1, using (12) and (5) of Theorem 2, we have

$$w_t(x_i(1+f)) = w_t(x_i) - w_t(x_i f) \ and \ w_t(x_i x_j(1+f)) = w_t(x_i x_j) - w_t(x_i x_j f). \quad (12)$$

As a result, for all $n \ge 3$, there are

$$w_t(x_{n-1}x_n f_2(x) df_2(x)/dx_n) \ne 2^{-1}w_t(x_n f_2(x) df_2(x)/dx_n) = 2^{-1}w_t(x_{n-1} f_2(x) df_2(x)/dx_n), \quad (13)$$

or

$$w_t(x_{n-1}x_n ef_2(x)/ex_n) \ne 2^{-1}w_t(x_n ef_2(x)/ex_n) = 2^{-1}w_t(x_{n-1} ef_2(x)/ex_n), \quad (14)$$

and or (13) and (14) are not establishment at the same time. So $f_2(x)$ just correlation immune functions of order 1. That is, $f_2(x)$ are correlation immune functions.

2) The same as the proof of 1), the result can be proved that when $n = 4r+5$ $(r = 0,1,2,\cdots)$, $f_1(x) = f_0^2(x)$ are 1-order correlation immune functions, we omit it here.

Algebraic immunity of quadratic rotation symmetric H Boolean functions

In this section, we discuss the algebraic immunity of quadratic RS H Boolean functions.

Theorem 6. For the quadratic RS H Boolean functions $f_1(x)$ and $f_2(x)$, $f_1(x) = f_0^2(x)$ and $f_2(x) = f_0^1(x) + f_0^2(x)$, there are: 1) $AI(f_1(x)) = 2$; 2) when $n > 3$, $AI(f_2(x)) = 2$.

proof. 1) For $f_1(x)$, we have $df_1(x)/dx_n = \sum_{i=1}^{n-1} x_i$, $w_t(df_1(x)/dx_n) = 2^{n-1}$ and $df_1(x)/dx_n \cdot ef_1(x)/ex_n = 0$.

Let $h_1 = f_1(x)df_1(x)/dx_n + df_1(x)/dx_n$, then $h_1 f_1(x)df_1(x)/dx_n = 0$, $h_1 ef_1(x)/ex_n = 0$. Hence there are $h_1 f_1(x) = h_1 f_1(x)df_1(x)/dx_n + h_1 ef_1(x)/ex_n = 0$, and $w_t(h_1) = 2^{n-2} < 2^{n-1}$. So h_1 is an annihilator of $f_1(x)$. It is easy to deduce from Theorem 2: $\deg(f_1(x)df_1(x)/dx_n) = \deg(ef_1(x)/ex_n) = 3$. Then $\deg h_1 = 3$.

It is easy to deduce $w_t(ef_1(x)/ex_n) < 2^{n-1}$ from Theorem 2. Let $h_2 = 1 + df_1(x)/dx_n + ef_1(x)/ex_n$,then $\deg h_2 = 3$. Obviously there are $h_1 + h_2 = 1 + f_1(x)$ and $w_t(h_2) < 2^{n-1}$.

So $h_1 + h_2$ is an annihilator of $f_1(x)$,and we can get $\deg(h_1 + h_2) = 2$.

We can take $r_1 + r_2 = h_i$ $(i = 1,2)$, $r_1 r_2 = 0$ and $r_1 \neq r_2 \neq 0$.

Known by $w_t(h_1) = 2^{n-2} < 2^{n-1}$ and $w_t(h_2) < 2^{n-1}$, there must be $w_t(r_i) < 2^{n-1}$ $(i = 1,2)$, which says that r_i must not be linear functions. So we can get $\deg r_i \geq 2$ $(i = 1,2)$.

Since $\deg f_1(x) = 2$, $\deg(1 + f(x)) = 2$ as well,we can get that the algebraic degree of all annihilators of $f_1(x)$ is no lower than 2-degree , so $AI(f_1) = 2$.

2) For $f_2(x)$, when $n = 3$, there is $w_t(ef_2(x)/ex_n) = 2^{n-1}$. Hence $1 + f(x)$ must have 1st annihilator, 1st annihilator is $1 + df_2(x)/dx_n = ef_2(x)/ex_n$ .When $n > 3$, the algebraic immunity of $f_2(x)$ and $f_1(x)$ proof are same, we can obtain $AI(f_2) = 2$, we omit it here.

Remark 3: The proof of Theorem 6 gives a convenient method, which use derivative $df(x)/dx_n$ and e-derivative $ef(x)/ex_n$, solving annihilator for any function easily.

Example 2. For $n = 4$'s cubic rotation symmetric Boolean functions $f(x) = f_0^2(x) + f_0^3(x)$, using derivative $df(x)/dx_n$ and e-derivative $ef(x)/ex_n$, we can obtain that $w_t(f(x)) = 2^{n-2} + 2^{n-3}$, $w_t(df(x)/dx_n) = 2^{n-1} + 2^{n-2}$ and $w_t(ef(x)/ex_n) = 0$. We can conclude that, $f(x)$ should be have 1st annihilator. Owing to $ef(x)/ex_4 = ef(x)/ex_3 = ef(x)/ex_2 = ef(x)/ex_1 = 0$, solving this differential equation, we can get 1st annihilator $x_1 + x_2 + x_3 + x_4$ .So $AI(f) = 1$.

Conclusions

In this paper,using derivative and *e*-derivative of Boolean functions as research tools, we obtain a series of results, like the compatibility of propagation and various cryptographic properties of quadratic RSBFs. These results are of great significance and play a key role in theory and applications. If we don't use derivative and *e*-derivative, it is difficult to obtain these results. For example, there exists H Boolean functions in $f_0^3(x)$. In addition, the proof of Theorem 6 gives the method of solving annihilators via derivative and *e*-derivative.This method makes it simple and convenient to solve annihilators.

Furthermore, in this paper, we reveal the relationship between RSBFs and completely pure *k*-degree Boolean functions, and decompose RSBFs into single completely pure *k*-degree Boolean functions. It will provide convenience on studying the algebraic immunity and other cryptographic properties of RSBFs further and deeply.

Keywords: H Boolean functions; e-derivative; derivative; algebraic degree; algebraic immunity; correlation immunity

Abstract. Using the derivative of the Boolean function and the e-derivative defined by ourselves as research tools, going deep into the internal structure of Boolean functions, we study relationship of algebraic degree, correlation immunity and annihilators for H Boolean functions with a specific Hamming weight. We obtain the algebraic degree of the e-derivative which is a component of H Boolean functions decide the algebraic degree of H Boolean functions. Besides, we describe the characteristics of the algebraic degree of e-derivative for the correlation immune H Boolean functions. We also check the e-derivative of H Boolean functions can put annihilators, correlation immunity and algebraic degree of H Boolean functions together. Meanwhile, we also deduce a formula method to solving annihilators of H Boolean functions. Such researches are important in cryptographic primitive designs, and have significance and role in the theory and application range of cryptosystems.

Introduction

Boolean functions with a variety of secure cipher properties are the key factors to design the cryptosystem with the ability to resist multiple cipher attacks and good safety performance. It is of great importance for a security cryptosystem to study some properties of Boolean functions, which make the cryptosystem resist various attacks [1,3,5,6,10], such as high algebraic degree [2], high nonlinearity [4], the strict avalanche criterion and propagation [8,9], higher-order correlation immunity [6,7] and higher-order algebraic immunity [11]. But in the study we find that there are mutual checks between some properties of cipher security. If one kind of property was improved, the other would be reduced [12]. Therefore, the compatibility of Boolean functions with a variety of properties of cipher security has been an issue of concern. Among them, the algebraic immunity of Boolean functions is current central issues. On the study of algebraic immunity of Boolean functions, the relevance among algebraic immunity and other cipher security properties, the solving method of the high-order algebraic immune functions and the optimal algebraic immune functions, and the solving method of annihilators are central contents of the study. The main research methods we take as follows, such as algebraic analysis, spectral analysis, matrix analysis, weighting analysis, linear subspace analysis and cascade analysis. The above methods need to do multi-step calculations step-by-step to obtain the results, which are more complicated.

In this paper, using e-derivative and derivative as main research tools, we study the relations among algebraic degree, correlation immunity and the annihilators of H Boolean functions $f(x)$ with the Hamming weight of $2^{n-1}+2^{n-2}$ .We also study the relations among algebraic degree, correlation immunity, the annihilators of the lowest algebraic degree, e-derivative and derivative of $f(x)$.

Preliminaries

The derivative of Boolean functions is already a well known concept [13~15]. Now the e-derivative is defined here. The readers may refer to [16~19] for more information on e-derivative.

Definition 1: The e-derivative (e-partial derivative) of Boolean function $f(x_1, x_2, \cdots, x_n)$ with respect to r variables $x_{i1}, x_{i2}, \cdots, x_{ir}$ $(i, r, i_1, ..., i_r \in [1, n])$ is defined as

$$ef(x)/e(x_{i1}, x_{i2}, \cdots, x_{ir}) = f(x_1, x_2, \cdots, x_{i1}, x_{i2}, \cdots, x_{ir}, \cdots, x_n) f(x_1, x_2, \cdots, 1+x_{i1}, 1+x_{i2}, \cdots, 1+x_{ir}, \cdots, x_n). \quad (1)$$

Remark 1: If $r = 1$, (1) turns into the e-derivative with respect to a single variable, which is denoted by $ef(x)/ex_i$ $(i = 1, 2, \cdots, n)$. As a result, the simplified form below can be easily derived.

$$ef(x)/ex_i = f(x_1, x_2, \cdots, x_{i-1}, 1, x_{i+1}, \cdots, x_n) f(x_1, x_2, \cdots, x_{i-1}, 0, x_{i+1}, \cdots, x_n) \ (i = 1, 2, \cdots, n).$$

Definition 2: The Hamming weight of n-dimensional Boolean functions $f(x) = f(x_1, x_2, \cdots, x_n) \in GF(2)^{GF(2)^n}$ is the number of elements contained in set $\left\{(x_1, x_2, \cdots, x_n) \middle| (x_1, x_2, \cdots, x_n) \in GF(2)^n, f(x_1, x_2, \cdots, x_n) = 1\right\}$, which denoted by $w_t(f(x))$ or $w_t(f)$. That is

$$w_t(f(x)) = \left|\left\{(x_1, x_2, \cdots, x_n) \middle| (x_1, x_2, \cdots, x_n) \in GF(2)^n, f(x_1, x_2, \cdots, x_n) = 1\right\}\right|.$$

Definition 3: For any arbitrary $\varepsilon_i = (0, 0, \cdots, 0, 1, 0, \cdots, 0)$ $(1 \le i \le n)$, If $f(x) = f(x_1, x_2, \cdots, x_n) \in GF(2)^{GF(2)^n}$ holds:

$$w_t(f(x+\varepsilon_i) + f(x)) = 2^{n-1}. \quad (2)$$

In (2), ε_i stands for n-dimensional Boolean vectors, which the i-th component is 1 and other components are 0. Then $f(x)$ was called an H Boolean function.

An H Boolean function is a Boolean function with propagation of degree 1.

Remark 2: The cascade function defined by (8) is more convenient to use than $f(x) = (1+x_{n+1}) f_1(x) + x_{n+1} f_2(x)$, which typically appears in classical cryptography, although these two definitions are essentially identical. For instance, with given H Boolean functions $g_{21} = 1 + x_n + x_{n-1}x_n$ and $g_{22} = 1 + x_{n-1} + x_{n-1}x_n$ of weight $2^{n-1} + 2^{n-2}$, $f_1(x) = (1+x_{n-2}) g_{21} + x_{n-2} g_{22}$ is the cascade of order g_{21} and g_{22}, whereas $f_2(x) = (1+x_{n+1}) g_{21} + x_{n+1} g_{22}$ is equivalent to $f_3(x) = (1+x_{n-2}) g_{22} + x_{n-2} g_{21}$, which is nothing but a cascade with a different order.

Definition 4: For any arbitrary ω $(\omega = (\omega_1, \omega_2, \cdots, \omega_n) \in GF(2)^n,\ 1 \le w_t(\omega) \le m)$, $f(x) = f(x_1, x_2, \cdots, x_n) \in GF(2)^{GF(2)^n}$ holds:

$$w_t(f(x) + \omega x) = 2^{n-1}. \quad (3)$$

In (3), $\omega x = \omega_1 x_1 + \omega_2 x_2 + \cdots + \omega_n x_n$ is a linear function. In this situation, Boolean functions $f(x)$ was called a m-order correlation immune function. the correlation immunity order is written as $CI(m)$.

Definition 5: If $w_t(f(x)) = r \ne 0$, suppose that $g(1+f) = 0$ and $w_t(g) = s \le r$, then function g is called a sub-function of function f with $gf = g$. Evidently, g is the annihilator of $1+f$, and any sub-function of $1+f$ is also the annihilator of f.

Lemmas 1~3 that follow describe properties of derivative and e-derivative of Boolean functions.

Lemma 1: A Boolean function is a propagation function of degree r iff

$$w_t(\partial f(x)/\partial(x_{i1}, x_{i2}, \cdots, x_{ir})) = 2^{n-1} \ (i, r, i_1, ..., i_r \in [1, n]).$$

Lemma 2: A Boolean function is an H Boolean function, iff the following equations hold for all x_i:

$$w_t(df(x)/dx_i) = 2^{n-1} \ (i = 1, 2, \cdots, n).$$

Lemma 3: For any arbitrary Boolean function, the following equations are true:

$$f(x) = f(x)\partial f(x)/\partial(x_{i1}, x_{i2}, \cdots, x_{ir}) + ef(x)/e(x_{i1}, x_{i2}, \cdots, x_{ir}) \ (i, r, i_1, ..., i_r \in [1, n]),$$

$$f(x) = f(x)df(x)/dx_i + ef(x)/ex_i \ (i = 1, 2, \cdots, n),$$

$$w_t(f(x)) = w_t(f(x)df(x)/dx_i) + w_t(ef(x)/ex_i) = 2^{-1} w_t(df(x)/dx_i) + w_t(ef(x)/ex_i) \ (i = 1, 2, \cdots, n).$$

Relationship among derivative, e-derivative, algebraic degree, correlation immunity and the annihilators

In this section,we reveal the relations among the e-derivative, derivative, the algebraic degree, correlation immunity, and the annihilator of H Boolean function with $w_t(f(x)) = 2^{n-1} + 2^{n-2}$.

The derivative of Boolean functions is necessary to be used to calculate the algebraic degree of H Boolean functions. Thus, Theorem 1 and Theorem 2 are introduced here firstly. Theorem 1 describes that how to calculate the algebraic degree of Boolean functions with the aid of their derivatives, and Theorem 2 describes the characteristics of the algebraic degree of e-derivative for the correlation immune H Boolean functions with the Hamming weight of $2^{n-1} + 2^{n-2}$.

Theorem 1[19]***:*** For any Boolean function $f(x)$, $\deg f(x) = m$ iff $\deg(df(x)/dx_i) \le m-1$ $(i = 1, 2, \cdots, n)$. And there exists an $i_0 \in \{1, 2, \cdots, n\}$, such that $\deg(df(x)/dx_{i_0}) = m-1$.

Theorem 2[19]***:*** Suppose that an H Boolean function $f(x)$ with the Hamming weight $2^{n-1} + 2^{n-2}$ and correlation immunity. If $ef(x)/ex_n$ is affine, i.e. $\deg ef(x)/ex_n = 1$, then the number of variables of $ef(x)/ex_n$ is greater than 1.

Theorem 3: For the H Boolean function $f(x)$ with the Hamming weight $2^{n-1} + 2^{n-2}$,

1. $\deg ef(x)/ex_n = 1$ iff $\deg f(x) = 2$.

2. If $\deg f(x) = 2$ and $CI(f(x)) = m \ge 1$,

$AI(f(x)) \le CI(f(x)) < ef(x)/ex_n$ contains the number of variables. (4)

Proof:

1. (sufficiency)

By Lemma 3, we can know, there is

$f(x) = f(x)df(x)/dx_n + ef(x)/ex_n$. (5)

Now, we prove $\deg ef(x)/ex_n = 1$. Adopt contradiction proof. Suppose $\deg ef(x)/ex_n > 1$, without loss of generality, we may assume $\deg ef(x)/ex_n = 2$. Since $w_t(f(x)) = 2^{n-1} + 2^{n-2}$,

$\deg df(x)/dx_n = \deg(1 + ef(x)/ex_n) = 2$.

By the properties of derivative, there must be $\deg f(x)df(x)/dx_n \ge 3$.

Known by (5), $\deg f(x) \ge 3$. That is a contradiction with $\deg f(x) = 2$, and it can only be

$\deg ef(x)/ex_n \le 1$. (6)

By Lemma 3 and $w_t(f(x)) = 2^{n-1} + 2^{n-2}$, one knows that $w_t(ef(x)/ex_n) = 2^{n-1}$. So

$\deg ef(x)/ex_n > 0$. (7)

Combining of (6) and (7), we have $\deg ef(x)/ex_n = 1$.

(necessity)

If $\deg ef(x)/ex_n = 1$, known from the properties of e-derivative, $ef(x)/ex_n$ of linear functions only can be x_{n-1}, $x_i + x_{n-1}$ $(i = 1, 2, \cdots, n-2)$, $x_i + x_j + x_{n-1}$ $(i, j = 1, 2, \cdots, n-2, i \ne j)$, $\cdots$, $x_1 + x_2 + \cdots + x_{n-2} + x_{n-1}$,etc (or the corresponding affine functions), or $x_1 + x_2 + \cdots + x_{n-2}$. When $ef(x)/ex_n$ is not equal to $x_1 + x_2 + \cdots + x_{n-2}$, since $f(x)$ is an H Boolean function with the Hamming weight $2^{n-1} + 2^{n-2}$, there must be $\begin{cases} w_t(ef(x)/e(x_{n-1}x_n)) = 2^{n-1} \\ w_t(\partial f(x)/\partial(x_{n-1}x_n)) = 2^{n-1} \end{cases}$, and $\begin{cases} e(ef(x)/e(x_{n-1}x_n))/ex_n = 0 \\ d(ef(x)/e(x_{n-1}x_n))/dx_n = 1 \end{cases}$.

We can know, $ef(x)/e(x_{n-1}x_n)$ is a linear function with the term of $x_{n-1} + x_n$ (or the corresponding affine function), that is $\deg(ef(x)/e(x_{n-1}x_n)) = 1$. We can get

$\deg(f(x)df(x)/dx_n) = 2$. (8)

By the Lemma 3, (8) and $\deg(ef(x)/ex_n) = 1$,we can know, $\deg f(x) = 2$.

When $ef(x)/ex_n$ is equal to $x_1 + x_2 + \cdots + x_{n-2}$, obviously, $f(x) = \sum_{i=1}^{n} x_i + (x_{n-1} + x_n)\sum_{i=1}^{n-2} x_i$, then $\deg f(x) = 2$.

2. Because $\deg f(x) = 2$, known by the 1 of Theorem 3,

$\deg ef(x)/ex_n = 1$. (9)

By the Lemma 3, there is

$ef(x)/ex_n(1+f(x)) = ef(x)/ex_n + ef(x)/ex_n f(x)df(x)/dx_n + ef(x)/ex_n ef(x)/ex_n = 0$. (10)

Known from (9) and (10), $AI(f(x)) = 1$. For any ωx $(\omega, x \in GF(2)^n)$ of $w_t(\omega) \geq 1$, we can deduce

$w_t(f(x)+\omega x) = w_t(f(x)df(x)/dx_n + \omega x) + w_t(ef(x)/ex_n + \omega x) - w_t(\omega x)$. (11)

Thanks to $\max_{\omega x} w_t(f(x)df(x)/dx_n + \omega x) = 2^{n-1} + 2^{n-2}$, by (11) and known correlation immunity of $f(x)$, we can know, there must be

$w_t(ef(x)/ex_n + \omega x) \neq 0$. (12)

By known $CI(f(x)) = m \geq 1$, the concept of *m*-order correlation immunity, (12) and $ef(x)/ex_n$ is a linear function, there must be

$CI(f(x)) < ef(x)/ex_n$ contains the number of argument. (13)

By $AI(f(x)) = 1$ and (13), we can judge (4) is set up and this completes the proof.

Remark 3: The (11) and (12) are set up for any non-linear Boolean functions,and the variables' number of $\max ef(x)/ex_n$ contain is $n-1$.

Theorem 4: For the H Boolean function $f(x)$ with $w_t(f(x)) = 2^{n-1} + 2^{n-2}$, if $\deg ef(x)/ex_n = 1$, $\deg ef(x)/ex_i = 1$ $(i = 1,2,\cdots,n-1)$.

Proof: By the known conditions and Theorem 3, there must be $\deg f(x) = 2$.

Suppose $\deg ef(x)/ex_i \neq 1$ $(i \neq n)$. Without loss of generality, we can assume

$\deg ef(x)/ex_i = 2$ $(i \neq n)$. (14)

Since H Boolean function $f(x)$ with $w_t(f(x)) = 2^{n-1} + 2^{n-2}$, By Lemma 2 and 3, we have

$w_t(ef(x)/ex_i) = 2^{n-1}$ $(i \neq n)$. (15)

By (14) and (15), one knows that

$\deg df(x)/dx_i = \deg(1+ef(x)/ex_i) = 2$ $(i \neq n)$. (16)

Since

$d(f(x)df(x)/dx_i)/dx_i = df(x)/dx_i + f(x)d(df(x)/dx_i)/dx_i + df(x)/dx_i d(df(x)/dx_i)/dx_i = df(x)/dx_i$. (17)

By (16) and (17), we can know, $\deg(f(x)df(x)/dx_i) \geq 3$ $(i \neq n)$.

By Lemma 3, we can get $\deg f(x) \geq 3$. It conflicts with the known $\deg f(x) = 2$.

And i is any one of $\{1,2,\cdots,n-1\}$, then there must be

$\deg ef(x)/ex_i = 1$ $(i = 1,2,\cdots,n-1)$.

The proof ends.

Theorem 5: An H Boolean function $f(x)$ has,

$w_t(f(x)) = 2^{n-1} + 2^{n-2}$, (18)

$\partial f(x)/\partial(x_{n-4}x_{n-3}x_{n-2}x_{n-1}x_n) = 0$, (19)

and

$$\begin{cases} w_t(\partial f(x)/\partial(x_{n-1}x_n)) = 2^{n-2} \\ w_t(ef(x)/e(x_{n-1}x_n)) = 2^{n-1} + 2^{n-3} \end{cases}. \quad (20)$$

Then $CI(f(x)) = 1$ and $1+f(x)$ has the annihilators of linear function

$(x_{n-1}+x_n)ef(x)/e(x_{n-1}x_n) + e((1+x_{n-1}+x_n)ef(x)/e(x_{n-1}x_n))/ex_{n-2} = x_{n-4} + x_{n-3} + x_{n-1} + x_n$. (21)

Proof: Since $f(x)$ is an H Boolean function which satisfies (18), by the Lemma 3, we can know

$$\begin{cases} w_t(f(x)df(x)/dx_i) = 2^{n-2} \\ w_t(ef(x)/ex_i) = 2^{n-1} \end{cases} (i = 1,2,\cdots,n). \quad (22)$$

Because $f(x)$ satisfies (19), there are $w_t(f(x)|x_i = 0) = w_t(f(x)|x_i = 1) = 2^{-1}w_t(f(x))$. So $f(x)$ is a correlation immune function of order 1,and $CI(f(x)) = 1$.

Since $f(x)$ is an H Boolean function, for all ωx $(\omega, x \in GF(2)^n)$, we have

$$w_t(d(f(x)+\omega x)/dx_i)=2^{n-1}\ (x_i\neq\omega x). \tag{23}$$

Since $f(x)$ is a correlation immune function of order 1,moreover there are (23) and Lemma 3, when $\omega x\neq x_i$,for all ωx $(\omega,x\in GF(2)^n)$ of $w_t(\omega)=1$, we have

$$w_t(e(f(x)+\omega x)/ex_i)=w_t(ef(x)/ex_i)-2w_t(\omega xef(x)/ex_i)-w_t(\omega xdf(x)/dx_i)+w_t(\omega x)=2^{n-2}. \tag{24}$$

By (22) and (24), there are

$$w_t(\omega xdf(x)/dx_i)+2w_t(\omega xef(x)/ex_i)=2^{n-1}+2^{n-2}. \tag{25}$$

Since $f(x)$ is an H Boolean function which satisfies (18), by the Lemma 2, we can know

$$w_t(\omega xdf(x)/dx_i)+w_t(\omega xef(x)/ex_i)=w_t(\omega x)=2^{n-1}. \tag{26}$$

The solution of the simultaneous equations of (25) and (26) is

$$\begin{cases} w_t(\omega xdf(x)/dx_i)=2^{n-2} \\ w_t(\omega xef(x)/ex_i)=2^{n-2} \end{cases}. \tag{27}$$

So

$$\begin{cases} w_t(x_{n-1}df(x)/dx_n)=2^{n-2} \\ w_t(x_{n-1}ef(x)/ex_n)=2^{n-2} \end{cases}. \tag{28}$$

Based on correlation immunity of order 1 of $f(x)$ and Lemma 3, for all ωx $(\omega,x\in GF(2)^n)$ of $w_t(\omega)=1$, there is

$$\begin{aligned} &w_t(f(x)+\omega x) \\ &=w_t(f(x)df(x)/dx_n)-2w_t(\omega xf(x)df(x)/dx_n)+w_t(ef(x)/ex_n)-2w_t(\omega xef(x)/ex_n)+w_t(\omega x). \\ &=2^{n-1} \end{aligned} \tag{29}$$

By (22), (27) and (29), we have $w_t(\omega xf(x)df(x)/dx_n)=2^{-1}w_t(f(x)df(x)/dx_n)=2^{n-3}$. So

$$w_t(x_{n-1}f(x)df(x)/dx_n)=2^{-1}w_t(f(x)df(x)/dx_n)=2^{n-3}. \tag{30}$$

By (20), (28), (30), (18) and (22), we can get

$$\begin{cases} w_t((x_{n-1}+x_n)\partial f(x)/\partial(x_{n-1}x_n))=2^{n-2} \\ w_t((x_{n-1}+x_n)ef(x)/ex_n)=2^{n-2} \\ w_t((1+x_{n-1}+x_n)\partial f(x)/\partial(x_{n-1}x_n))=0 \\ w_t((1+x_{n-1}+x_n)ef(x)/ex_n)=2^{n-2}+2^{n-3} \end{cases}. \tag{31}$$

Known by (31), (18), (22) and (19), $1+f(x)$ has 1-degree annihilator $g=x_{n-4}+x_{n-3}+x_{n-1}+x_n$, and there is a relationship of (32) between g and $f(x)$,

$$g=(x_{n-1}+x_n)ef(x)/e(x_{n-1}x_n)+e((1+x_{n-1}+x_n)ef(x)/e(x_{n-1}x_n))/ex_{n-2}, \tag{32}$$

The proof ends.

Remark 4: By the Theorem 7, we can know, the annihilators of the lowest algebraic degree of $f(x)$ can be represented and obtained by (21). Meanwhile, by Theorem 1 to 5, we can find, there is $\deg ef(x)/ex_n+1=\deg(f(x)df(x)/dx_n)=\deg f(x)$. This is the inevitable property.

Conclusions

In this paper ,we get the relevance of algebraic degree, correlation immunity and the annihilators for H Boolean functions with $w_t(f(x))=2^{n-1}+2^{n-2}$. As a result, we get some new conclusions about the compatibility of some properties such as propagation, correlation immunity, algebraic degrees of Boolean functions, and we also get a new and relatively simple method for solving the annihilators. It is shown that the most crucial factor that impacts and combines the above characteristics is the e-derivative $ef(x)/ex_n$ and a combination of $f(x)df(x)/dx_n$ and $ef(x)/ex_n$. It can be seen that the e-derivative play an important role while dealing with the compatibility among the different cryptography properties. The research in the current paper is fundamental and could be extended toward the problems on compatibility among the different cryptography properties of other types of H Boolean functions such as Bent functions, resilient functions, and rotational symmetric functions.

Keywords: Edge detection. Vehicle image. Background subtraction. YCbCr

Abstract. In this paper, we propose the spatial domain based vehicle detection scheme. This proposed scheme combines the Sobel edge detection method with background subtraction in YCbCr color space. The scheme detects the vehicle in Y(Luminance), Cb and Cr(chrominance) components of the vehicle image using background subtraction and combines the three images. Edge detection method determines edge information of the luminance component of the vehicle image. The image combined with edge detection and background difference is implemented filling and filtering operation. The robustness of the proposed scheme is analyzed considering different types of vehicle image.

Introduction

The real-time traffic flow information is an important support for ITS. Video detection is a modern and effective measure in detection of the traffic flow at a low cost. Therefore, vehicle detection based on vision has become a research focus nowadays[1-3]. Background subtraction as a kind of video detection has became an important method of researching and applying vehicle detection technology[4]. The color space representation has played a major role in image recognition. Furthermore, color has become more recently a major component in video vehicle detection applications[5-6]. Because YCbCr color space can obviate the evocable effect of variational illumination, many researchers use it in video vehicle detection[7]. Edge detection method can detect the profile of vehicle. In order to get complete vehicle information, this paper combines the Sobel edge detection method with background subtraction in YCbCr color space.

The paper is organized as follows: In Section 2 the edge detection algorithm is selected and explained. The proposed schemes are described in Section 3. The results and discussions are given in Section 4. The paper is concluded in Section 5.

Sobel edge detection algorithm

According to the different operator, edge detection algorithm is divided into Sobel edge detection method, Canny edge detection method, Roberts edge detection method, Prewitt edge detection method etc. To select an optimal edge detection operator, we compare the effects of different edge detection algorithm. On Y component the Sobel, Canny and Roberts edge detection operators are applied to different vehicle image. Fig.1 shows the detection results. Where, Fig. 1(a) show Sobel edge detection images; Fig. 1 (b) give Canny edge detection results and Fig. 1 (c) Roberts edge detection images. From Fig. 1 (b), we can see that Canny edge detection can detect complete profile of the vehicle, but many background noise components are detected simultaneously. In Fig.1(c), Roberts edge detection algorithm detects incomplete vehicle profile. The Sobel edge detection algorithm shown in Fig.1(a) can not only detect complete vehicle profile but also reduce the background noise. So the Sobel edge detection algorithm is adopted in this scheme.

This scheme uses the Sobel edge detection method to determine the luminance component edge information of the vehicle image. When operating an image with Sobel edge detection, the following steps are implemented. Firstly, use Sobel operator to calculate the horizontal gradient and vertical gradient. Secondly, combine the gradient information of two directions. Finally, apply the

threshold processing to judge image edge and output edge detection results. Fig.2 are Sobel edge detection operators. Fig. 2(a) is a 3*3 area of image, Fig. 2(b) and Fig. 2(c) respectively acts as Sobel gradient operator of vertical direction and horizontal direction.

Proposed scheme

In digital image processing, besides RGB color space model is often used in collecting vidicon image, there are also HIS and YCbCr color space models. In YCbCr model, Y is luminance component, Cb is the blue and Cr red color chrominance component. This color space can obviate the evocable effect of variational illumination, so in the paper the YCbCr color model is adopted. This scheme combines the Sobel edge detection method with background subtraction method to detect the moving vehicle. The proposed scheme uses the foreground vehicle image ForeI and background image BackI of size m×n as the original images. The two images are transformed into R, G and B components of size m×n. Then R, G and B components are transformed into Y, Cb and Cr components using following equations:

$$Y = 0.299 \cdot R + 0.587 \cdot G + 0.114 \cdot B \quad (1)$$

$$Cb = 0.596 \cdot R - 0.275 \cdot G - 0.321 \cdot B \quad (2)$$

$$Cr = 0.212 \cdot R - 0.523 \cdot G - 0.311 \cdot B \quad (3)$$

The scheme mainly includes segmenting moving vehicles and removing the noise of image. Fig.3 shows the flow diagram of detection algorithm.

Part 1. Segmenting moving vehicles

Input: The original foreground image ForeI and background imge BackI of size m × n. Output: Binaryzation image O of size m1 × n1.

1) Separate R, G and B components of size m × n from foreground and background image.

2) Transform R, G and B components into Y, Cb, Cr components using (1), (2) and(3).

3) Considering the real-time demand of processing image, segment the interesting regions from Y, Cb, Cr components of background and background image according to the relation between the installation position of vidicon and roadway to get interested images size of m1×n1.

4) Determine edge information of Y component using Sobel method to get Y'.

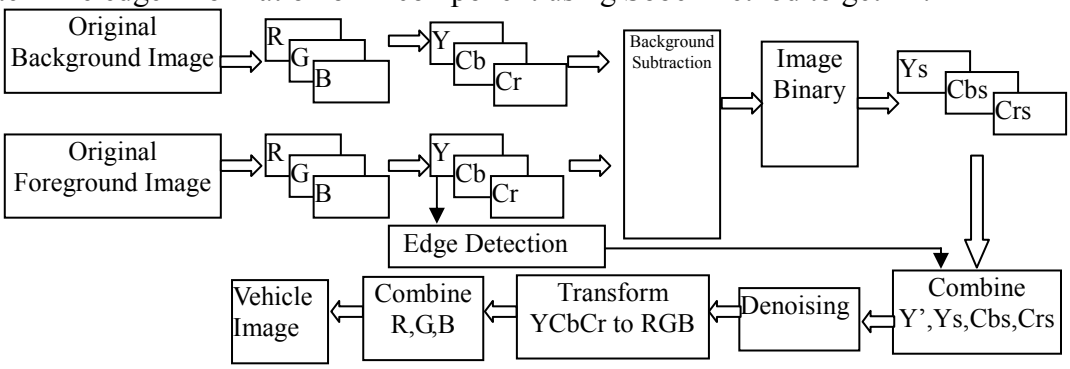

Fig. 3 Flow diagram of detection algorithm

5) Respectively subtract background image Y,Cb,Cr components from foreground image Y, Cb,Cr components.

6) Calculate the optimal threshold using following equation:

$$thy = \frac{\sum Y(i,j)}{m1 \times n1} + k \times \sqrt{\frac{\sum Y(i,j) - \frac{\sum Y(i,j)}{m1 \times n1}}{m1 \times n1}} \tag{4}$$

Where, thy is Y component threshold value, the first part is the mean value of the Y component, the second part is the root mean square of the Y component. k is an integer rang two to five. The equations of Cb and Cr components threshold values are the same with Y component threshold value. Segment image using these calculated threshold values we get three binaryzation images Ys,Cbs and Crs.

7) Combine edge detection image Y' and Ys,Cbs, Crs to generate image O.

Part 2. Denoise and output

Because the vidicon is commonly hanged on a high pole, noise caused by the slight moving vidicon is often included in the binaryzation image. When the texture of moving vehicle is simple, the detected object is easy to part and fall to pieces even has holes within an object. So noise removal is necessary. The main processes include:

8) Considering vehicle character, eliminate all regions falling short of vehicle character. In this arithmetic, the acreage, long and broad ratio are accounted.

9) Mean filter to get O1.

10)Transform Y, Cb, Cr components of image O into R, G, B components.

11) Combine R,G and B components to get result image and display the image in LCD screen.

Results and discussions

The series of experiments are conducted to analyze the algorithm on the vehicle images. In these experiments, the video images are captured from real traffic scene of a throughway. The collected speed is 30 frames per second and the size of every image is 640*480.

Fig.4 show different foreground vehicle images and corresponding processed images. In Fig.4,(a) and (f)foreground image;(b) and (g)YCbCr color space binaryzation image; (c) and (h) combined image of edge detection and binaryzation image; (d) and (i) the image of filling holes; (e) and (j) denoised image.From the images we can see that YCbCr binaryzation image combined with the edge detection information can get relatively complete vehicle image but include some background images and holes in vehicles(seen Fig4.(c)and (h)). Through filling operation some holes are filled with white(object) color and get complete vehicle images(seen Fig4.(d)and (i)).The mean filter operation is implemented to eliminate all regions falling short of vehicle character(seen Fig4.(e)and(j)). From the results we can see that the proposed scheme in this paper can detect complete vehicles.

Conclusion

We have proposed a spatial domain based vehicle detection scheme. The YCbCr components are considered to detect vehicle image. Sobel edge detection method determines edge information of

the luminance component of the vehicle image. We adopt background subtraction to get Y,Cb and Cr component images and do binaryzation processing. This scheme combines the Sobel edge detection method with background subtraction in YCbCr color space. The video vehicle detection scheme is analyzed by considering various types of image and the scheme was found robust to various types of image.
